Cooling.—When the wort has boiled the necessary time, it is turned into the hop-back to settle. The hop-back is a utensil made of wood or iron, and fitted with a false bottom of perforated plates; these plates retain the hops in the back, whilst the wort is drawn off into the coolers. The wort should be allowed fifteen or twenty minutes to settle in the back, and when run on to the coolers should be thoroughly bright. In many breweries coolers are not used, the wort running direct from the hop-back through the refrigerator into the fermenting tun. When practicable this is an excellent plan, for worts often take harm whilst lying exposed on the coolers. In every brewery of any note the worts are cooled artificially by means of a refrigerator. Of these there are several kinds, but all are constructed upon the same principle, which is that of allowing a thin stream of wort to trickle over pipes containing a running stream of water. The water is either run direct from the mains or is pumped by an engine from a well. In every instance it is necessary that the water shall be several degrees colder than the heat the wort is to be "pitched" at, as brewers call it, in other words, the heat at which the wort is let down into the fermenting tun. This "pitching heat" varies very much. Beers pitched at high heats, say from 62° to 66°, come soonest into condition, but do not keep so well. Under ordinary circumstances 60° appears to be the best heat at which to start fermentation, or, in the case of strong ale, 58°.

Fermentation.—The fermenting tun may be round or square, open or closed, and made of wood or stone. Stone squares are universal in the northern counties of England, but are rarely met with in the southern and midland counties. When beer is fermented in a stone or slate square, it should never be pitched at a lower heat than 66° or 68°; for these utensils are very cold, and therefore liable to check or stop the fermentation. Every fermenting tun should be fitted with an attemperator. The attemperator consists of a series of pipes fixed within the tun, and having its inlet and outlet on the outside. It should be possible to run hot or cold water through these pipes at any hour, so that the temperature of the gyle can be raised or lowered at pleasure. The work performed by that natural process which we call fermentation is the conversion of saccharine matter into alcohol. It plays a most important part in the brewer's art, and deserves his most careful attention. In order to obtain a quick and regular fermentation, the brewer employs yeast, or barm, as it is called in some parts of the country. Great care must be taken that the yeast used shall be perfectly fresh and healthy, for it must never be forgotten, that it is impossible to obtain a good fermentation from bad yeast. Yeast that comes from porter should never be used in pale or delicately flavoured ales, as it is apt to impart a burnt taste and high colour. The quantity of yeast required depends upon the strength of the wort and the quality of the water. Strong worts require more yeast than weak ones; and the same rule applies to hard waters as compared with soft. Worts of about 20 ℔ gravity should do well with 1 ℔ of yeast per barrel, whilst stronger worts require twice that quantity. As we have said, 60° seems to be the best heat at which to pitch wort, unless it is of a high gravity, or the fermenting tun be built in a very warm place, in which case the temperature of 58° will not be too low.

The appearance of a gyle of beer during the earlier stages of a good fermentation is very beautiful. At first the whole surface is covered with a thick white foam, which, within a few hours, curls itself into every imaginable shape and form. This increases in height, until it presents the appearance of a number of jagged rocks of snowy whiteness. With these the artistic beauties of the fermentation disappear, although the fine thick head of yeast which follows delights the eye of the practised brewer, for it tells him that his fermentation is drawing towards a successful end. But the progress of the fermentation must not be judged by appearances alone. Samples should be taken from the tun at least twice a day, and weighed with the saccharometer. By this means the brewer tells at what speed the sugar is being converted into alcohol; and when he considers the process has gone far enough, he stops it by taking away the yeast, which operation is termed cleansing. At the end of the first twenty-four hours, the gyle should attenuate 1 ℔ in every three or four hours, whilst the temperature should rise from 1° to 2° during the same space of time. The fermentation may proceed quicker than this without any harm ensuing; but if it does not reach the *minimum* speed of 1 ℔ in four hours, it may be said to be sluggish, and requires assisting. This is done by "rousing" the gyle every two hours with a utensil made for the purpose. Wort fermented in stone or slate squares must be roused every hour and a half, without exception. If unchecked the temperature of the gyle will rise to 76° or even 80°. Any heat above 72° is likely to affect the beer injuriously, for at that temperature the acetous fermentation commences. At the same time, beers for quick consumption may be allowed to rise a few degrees higher, and will perhaps be improved by the increase of temperature. The attemperator must be used to prevent the gyle reaching too high a heat.

Cleansing is the act of removing the yeast from the beer, in order to stop the fermentation. There are three modes of cleansing—*1st*, by simply skimming the yeast off as it rises to the surface; *2d*, by running the beer into casks, and then allowing the yeast to work out through the bung holes; and *3d*, on what is called the Union, or Burton system, which is the second plan with some improvements. When beer is cleansed in the second or third mode, it is necessary to keep the casks or Unions full to the bung. They must, therefore, be refilled every two hours, either by hand or by a self-acting apparatus invented for the purpose. Brewers differ as to the time when the operation of cleansing should commence; and, indeed, it is difficult to fix any limit, as much depends upon the character of the ale and the appearance of the fermentation. In the writer's opinion strong ales, worked in casks or on the Burton system, should be cleansed when they have attenuated down to 12 or 14 ℔; weaker beers and pale ales should be allowed to go quite 2 ℔ lower before being cleansed. Stout and porter should be cleansed rather earlier than any kind of ale, in order that they may drink full in the month. When all the yeast has worked out of the beer, it is ready for the last process.

Racking and Storing.—Ales intended for quick consumption should be racked so soon as clean, or they will be found flat and out of condition. A few of the finest hops should be put into the cask; and in the case of pale ale the quantity should not be less than 1 ℔ to the barrel. The finest strong and India pale ale should be stored between two and three months before being tapped, and even at that age, must be considered young. Ales intended to be stored some months should have a porous vent peg placed in the shive to keep the ale from fretting, and save the head of the cask from being blown out. (S. A. W.)

BREWSTER, Sir David, natural philosopher, distinguished especially for his original discoveries in the science of optics and his numerous and varied contributions to scientific literature, was born on the 11th December 1781 at Jedburgh, where his father, a teacher of high reputation, was rector of the grammar school. At the early age of twelve he was sent to the University of Edinburgh, being intended for the clerical profession. Even before this, however, he had shown a strong inclination for physical inquiries, which had been fostered by his intimacy with a "self-taught philosopher, astronomer, and mathematician," as Sir Walter Scott called him, of great local fame—James Veitch of Inchbonny. Veitch was particularly skilful in making telescopes, and may thus have had some influence in determining the precise direction of his young companion's future researches. Though he duly finished his theological course and was licensed to preach, Brewster's natural preference for other pursuits, combined with a constitutional nervousness, prevented him from engaging in the active duties of his profession. In 1799 he was induced by his fellow-student, Brougham, to study the inflection of light, repeating Newton's experiments; and from this date he carried on, almost without interruption, the course of original discovery in the science of physical optics which constitutes one of his chief claims to distinction. The results of his investigations were communicated from time to time in papers to the *Philosophical Transactions* of London and other scientific journals, and were admirably and impartially summarized by Professor James D. Forbes in his preliminary dissertation to the eighth edition of this Encyclopædia. The fact that other philosophers, notably Malus and Fresnel, were pursuing the same investigations contemporaneously in France does not invalidate Brewster's claim to independent discovery, even though in one or two cases the priority must be assigned to others.

The most important subjects of his inquiries are enumerated by Forbes under the following five heads:—1. The laws of polarization by reflection and refraction, and other quantitative laws of phenomena; 2. The discovery of the polarizing structure induced by heat and pressure; 3. The discovery of crystals with two axes of double refraction, and many of the laws of their phenomena, including the connection of optical structure and crystalline forms; 4. The laws of metallic reflection; 5. Experiments on the absorption of light. In this line of investigation the prime importance belongs to the discovery (1) of the connection between the refractive index and the polarizing angle, (2) of biaxal crystals, and (3) of the production of double refraction by irregular heating. These discoveries were promptly acknowledged by those best qualified to estimate their value. So early as the year 1807 the degree of LL.D. was conferred upon Brewster by Marischal College, Aberdeen; in 1815 he was made a member of the Royal Society of London, and received the Copley medal; in 1818 he received the Rumford medal of the Society; and in 1816 the French Institute awarded him one-half of the prize of three thousand francs for the two most important discoveries in physical science made in Europe during the two preceding years. Among the non-scientific public his fame was spread more effectually by the invention, in 1816, of the elegant philosophical toy, the kaleidoscope, for which there was so great a demand both in England and America that for some time the supply could not meet it. An instrument of higher interest, the stereoscope, which, though of much later date (1849–50), may be mentioned here, since along with the kaleidoscope it did more than anything else to popularize his name, was not, as has often been asserted, the invention of Brewster. Wheatstone discovered its principle and applied it as early as 1838 to the construction of a cumbrous but effective instrument, in which the binocular pictures were made to combine by means of mirrors. To Brewster is due the merit of suggesting the use of lenses for the purpose of uniting the dissimilar pictures; and, accordingly, the lenticular stereoscope, now in exclusive use, may fairly be said to be his invention. A much more valuable practical result of Brewster's optical researches may be traced in the vast improvement of the lighthouse system during the last half century. It is true that the dioptric apparatus was perfected independently by Fresnel, who had also the satisfaction of being the first to put it into operation, the French Government being in this, as in many other cases, quicker than the English to perceive the value of new scientific discoveries. But it is indisputable that Brewster was earlier in the field than Fresnel; that he described the dioptric apparatus in 1812; that he pressed its adoption on those in authority at least as early as 1820, two years before Fresnel suggested it; and that it was finally introduced into British lighthouses mainly by his persistent efforts. The tribute paid to his memory by his successor at the head of the University of Edinburgh was therefore as just as it was graceful:—"Every lighthouse that burns round the shores of the British empire is a shining witness to the usefulness of Brewster's life."

Brewster's own discoveries, important though they were, were not his only, perhaps not even his chief, service to science. The extent and variety of his contributions to scientific literature were little short of marvellous. He commenced literary work in 1799 as a regular contributor to the *Edinburgh Magazine*, of which he acted as editor at the age of twenty. In 1807 he entered on a much larger undertaking, which cost him long continued labour, and, especially towards its close, great vexation and anxiety. The chance suggestion of a friend, who knew his varied powers, led to the projection, under his editorship, of the *Edinburgh Encyclopædia*, of which the first part appeared in 1808, and the last not until 1830. The work was, as might have been expected, strongest in the scientific department, and many of its most valuable articles were from the pen of its editor. At a later period he was one of the leading scientific contributors to the *Encyclopædia Britannica* (seventh and eighth editions), the articles Electricity, Hydrodynamics, Magnetism, Microscope, Optics, Stereoscope, Voltaic Electricity, &c., being from his pen. In 1819 Brewster undertook further editorial work by establishing, in conjunction with Jameson, the *Edinburgh Philosophical Journal*, which took the place of the *Edinburgh Magazine*. After a time the title was again changed to the *Edinburgh Journal of Science*, sixteen volumes of which appeared under Brewster's sole editorship, with very many articles from his own pen. To the transactions of various learned societies he contributed from first to last between three and four hundred papers, and few of his contemporaries wrote so much for the various reviews. In the *North British Review* alone seventy-five articles of his appeared. A list of his larger separate works will be found below. Special mention, however, must be made of the most important of them all—his biography of Newton. In 1831 he published a short popular account of the philosopher's life in Murray's *Family Library*; but it was not until 1855 that he was able to issue the much fuller *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, a work which embodied the results of more than twenty years' patient investigation of original manuscripts and all other available sources.

Brewster's relations as editor brought him into frequent communication with the most eminent scientific men, and he was naturally among the first to recognize the benefit

that would accrue from regular intercourse among labourers in the field of science. In an article in the *Quarterly Review* he threw out a suggestion for "an association of our nobility, clergy, gentry, and philosophers," which was taken up by others and found speedy realization in the British Association for the Advancement of Science. Its first meeting was held at York in 1831; and Brewster, along with Babbage and Herschel, had the chief part in shaping its constitution. It was this service mainly that was referred to when it was said of him after his death that "the improved position of men of science in our times is chiefly due to Sir David Brewster." In the same year in which the British Association held its first meeting Brewster received the honour of knighthood and the decoration of the Guelphic order of Hanover. In 1838 he was appointed principal of the united colleges of St Salvator and St Leonard, St Andrews. Two of the highest honours of the scientific world were conferred upon him in 1849, when he filled the office of president of the British Association and was elected one of the eight foreign associates of the Institute of France in succession to Berzelius. In 1859 he accepted the office of principal of the University of Edinburgh, the duties of which he continued to discharge vigorously until within a few months of his death, which took place at Allerly, Melrose, on the 10th February 1868.

In estimating Brewster's place among scientific discoverers the chief thing to be borne in mind is that the bent of his genius was not characteristically mathematical. His method was empirical; he was a painstaking and accurate observer and classifier of facts rather than a theorizer; and the laws which he established, some of them, as has been pointed out, of prime importance, were generally the result of repeated experiment. To the ultimate explanation of the phenomena with which he dealt he contributed nothing, and it is noteworthy in this connection, that if he did not maintain to the end of his life the corpuscular theory he never explicitly adopted the undulatory theory of light These limitations, however, are to be taken as characterizing his genius rather than as detracting from it. Few will be inclined to dispute the verdict of Forbes:—"His scientific glory is different in kind from that of Young and Fresnel; but the discoverer of the law of polarization, of biaxal crystals, of optical mineralogy, and of double refraction by compression, will always occupy a foremost rank in the intellectual history of the age." In addition to the various works of Brewster already noticed the following may be mentioned:—Notes and Introduction to Carlyle's translation of Legendre's *Elements of Geometry* (1824); *Treatise on Optics* (1831); *Letters on Natural Magic*, addressed to Sir Walter Scott (1831); *The Martyrs of Science, or the Lives of Galileo, Tycho Brahe, and Kepler* (1841); *More Worlds than One* (1854). (See *The Home Life of Sir David Brewster*, by his daughter Mrs Gordon.)

BRIANÇON, a very strongly fortified town of France, the capital of an arrondissement in the department of Hautes-Alpes, situated on a hill about 4300 feet above the level of the sea, near the source of the Durance, in lat. 44° 53′ N. and 6° 47′ E. long. It commands the road across Mount Genèvre between France and Italy, and is well defended by its natural position; while the surrounding eminences are crowned with strong fortifications communicating with each other and the town by subterranean passages. The town itself is one of the highest in Europe, and the neighbouring village of St Veran has the loftiest situation of any in France. The principal buildings in Briançon are a church in the Italian style, the departmental prison, and a communal college. A single-arch bridge, 127 feet in span and 180 feet high, crosses the valley of the Clarée, affording access from the town to the principal parts of the fortifications. There is an extensive silk-factory in the old convent of St Catherine, which manufactures floss silk, stockings, hats, and other silk goods; and the other industrial articles in the town comprise small iron wares, leather, and lavender water. A considerable traffic is carried on in chalk, and in turpentine and other forest productions. The chalk, though known as Briançon chalk, is obtained at Fenestrelles in Piedmont; the Briançon manna is a kind of resin. Briançon is identified with *Brigantium*, a city of great antiquity and dubious origin, which became an important military post under the Romans. For a long time after the fall of the Roman empire it maintained itself as an independent republic, and was not united to France till 1349. Made over by the peace of Ryswick to the duke of Savoy, it was restored to France in 1713. In 1815 the town made a noble defence. Population in 1872, 3579.

BRIANSK, a town of Russia, in the government of Orloff, 98 miles E.N.E. of the city of that name, in 53° 15′ N. lat., and 22° 50′ E. long., on both banks of the Desna, opposite the mouth of the River Snezheta. It is divided into four parts by several smaller streams. The town is mentioned in 1146, and then bore the names of Briansk and Debriansk. It afterwards formed a separate principality, which came to an end in 1356 with the death of Prince Basil Alexandrovitch. After the Mongolian invasion Briansk and the whole Siever country fell under the power of the Lithuanians; but from time to time it was united with Russia, and finally became incorporated with the empire in the beginning of the 17th century in the reign of Michael Theodorovitch. Under the first Demetrius Briansk was taken by the rebels, but successfully resisted the attacks of the second impostor. Under the Empress Anna, according to the plan of Paul I., there was constructed a dock for the building of ships, but it was closed in 1739. In 1778 the town was made the capital of a department in Orloff, and in 1783 an arsenal, which still exists, was established for the manufacture of artillery. Briansk has thirteen churches, of which the cathedral was built in 1526, and restored in the end of the 17th century. In the sacristy is preserved a manuscript copy of the gospels in the writing of Michael Theodorovitch, which dates from 1637. In the convent of Peter and Paul is buried Oleg Romanovitch, prince of Chernigoff and Briansk, who lived in the 13th century. There are two high schools in the town, a hospital, and a dispensary; and the industrial establishments include rope-walks, tobacco-factories, brick-works, tallow-boiling works, flour-mills, and a brewery. A considerable trade is carried on, especially in wood, pitch, linseed-oil, and cattle, which are exported to Moscow and St Petersburg. There are markets twice a week, and one annual fair. In 1860 the population was 12,816, all of the Greek Church except 268 Catholics and 35 Jews. In 1867 it amounted to 13,881.

BRIAREUS, or ÆGÆON, one of the three hundred-armed (*Hekatoncheires*) sons of Uranus and Gaia,—his brothers being named Cottus and Gyges. The legends regarding them are various and somewhat contradictory. According to the most widely-spread myth, Briareus and his brothers were called by Zeus to his assistance when the Titans were making war upon Olympus. The gigantic enemies were defeated and consigned to Tartarus, at the gates of which the three brothers were placed. Other accounts make Briareus one of the assailants of Olympus, who, after his defeat, was buried under Mount Ætna. Homer mentions him as assisting Jupiter when the other Olympian deities were plotting against the king of gods and men. It would be difficult to determine exactly what natural phenomena are symbolized by the Hekatoncheires. They may represent the gigantic forces of nature which appear in earthquakes and other convulsions, or the multitudinous motion of the

sea waves. The latter interpretation is rendered more probable by the fact that Briareus is frequently called a marine deity, and is sometimes said to have been a son of Pontus and Gaia.

BRIBERY, as a public offence, may be defined as the administration of a bribe or reward, that it may be a motive in the performance of functions for which the proper motive ought to be a conscientious sense of duty. When this is superseded by the sordid impulses created by the bribe, a person is said to be corrupted, and thus corruption is a term sometimes held equivalent to bribery. The offence may be divided into two great classes,—the one characteristic of despotisms, where a person invested with power is induced by payment to use it unjustly; the other, which is an unfortunate characteristic of constitutional governments, where power is obtained by purchasing the suffrages of those who can impart it. The former offence is in every sense the more odious and formidable, and indeed it may be said, that until a country has outgrown it, there is no room for the existence of elective bribery, since the nations among which justice is habitually sold appear to be far below the capacity of possessing constitutional rights.

When Samuel in his old age challenges a rigid scrutiny of his conduct, he says, "Whose ox have I taken, or whose ass have I taken? or whom have I defrauded? whom have I oppressed? or of whose hands have I received any bribe to blind mine eyes therewith." And Amos, when denouncing the condition of the Israelites under Jeroboam, says, "They afflict the just, they take a bribe, and they turn aside the poor in the gate from their right." It is a natural propensity, removable only by civilization or some powerful counteracting influence, to feel that every element of power is to be employed as much as possible for the owner's own behoof, and that its benefits should be conferred not on those who best deserve them, but on those who will pay most for them. Hence judicial corruption is an inveterate vice of imperfect civilization. It is so deeply seated among Oriental races, that the attempts by controlling authority to eradicate it have been often futile. It has been the main impediment to the employment of natives in the British Eastern empire, since no external appearance of respectability, or apparent systematic routine of business, can be relied on as securities that the whole organization is not contaminated by systematic bribery. It is difficult to get the Oriental mind to understand how it is reasonable to expect the temptation of a bribe to be resisted. In the Russian empire this Oriental characteristic has had another conflict with the demands of a higher civilization. The organization of the Government requires that the empire should be honestly served by its official men, but their morality is of the humblest Oriental standard, and force will not change it. In no country, perhaps, has the offence been visited with more dire chastisement where it has been discovered, yet by the concurring testimony of all who are acquainted with Russian society, not only the official departments, but the courts of law are still influenced by systematic bribery. There is, perhaps, no other crime on which the force of law, if unaided by public opinion and morals, can have so little influence; for in other crimes, such as violence or fraud, there is generally some person immediately injured by the act, who can give his aid in the detection of the offender, but in the perpetration of the offence of bribery all the immediate parties obtain what they desire, and are satisfied.

The purification of the bench from judicial bribery has been gradual in most of the European countries. In France it received an impulse in the 16th century from the high-minded chancellor L'Hôpital. In England judicial corruption acquired a painful, but perhaps a wholesome renown, from the fate of the illustrious Bacon. In Scotland for some years after the Revolution the bench was not without a suspicion of interested partiality; but during the present century, at least, there has been in all parts of the empire a perfect reliance on its purity. The same may be said of the higher class of ministerial officers. There is no doubt that in the period from the Revolution to the end of Queen Anne's reign, when a speaker of the House of Commons was expelled for bribery, and the great Marlborough could not clear his character from pecuniary dishonesty, there was much corruption in the highest official quarters. The level of the offence of official bribery has gradually descended, until it has become an extremely rare thing for the humbler officers connected with the revenue to be charged with it. It has had a more lingering existence with those who, because their power is more of a constitutional than an official character, have been deemed less responsible to the public. During Walpole's administration there is no doubt that members of Parliament were paid in cash for votes; and the memorable saying, that every man has his price, has been preserved as a characteristic indication of his method of government.

One of the forms in which administrative corruption is most difficult of eradication is the appointment to office. It is sometimes maintained that the purity which characterizes the administration of justice is here unattainable, because in giving a judgment there is but one form in which it can be justly given, but when an office has to be filled many people may be equally fitted for it, and personal motives must influence a choice. It very rarely happens, however, that direct bribery is supposed to influence such appointments.

It does not appear that bribery was conspicuous in England until, in the early part of the 18th century, constituencies had thrown off the feudal dependence which lingered among them; and, indeed, it is often said, that bribery is essentially the defect of a free people, since it is the sale of that which is taken from others without payment. It is alluded to by Fielding and Smollett, and had become conspicuous in the days of Hogarth, who represents it in its double shape of demoralization; one picture shows a reckless expenditure of money among profligate expectants, whose demoralization is a systematic source of profit to them, while another presents us with the impoverished father of a family urged against his conscience to relieve the misery of his wife and children by the sale of his vote.

In England electoral bribery has been the subject of much legislation, which culminated in the Corrupt Practices Prevention Act of 1854 (17 and 18 Vict. c. 102). By this Act the following persons shall be deemed guilty of bribery, and shall be punishable accordingly:—

1. Every person who shall directly or indirectly, by himself or by any other person on his behalf, give, lend, &c., or offer, promise, or promise to procure, &c., any money or valuable consideration to or for any voter or any other person in order to induce any voter to vote or refrain from voting, or shall corruptly do any such act on account of such voter having voted or refrained from voting at any election.

2. Every person who shall similarly give or procure or promise, &c., any office, place, or employment to or for any voter or other person in order to induce him to vote, &c.

3. Every person who shall make any gift, loan, promise, &c., as aforesaid to any person to induce such person to procure the return of any person to serve in Parliament or the vote of any voter.

4. Every person who shall, in consequence of such gift, procure or engage, promise or endeavour to procure the return of any person or the vote of any voter.

5. Every person who shall pay any money with the

intent that it should be spent in bribery, or who shall pay money in repayment of any money wholly or in part expended in bribery.

Persons so offending are guilty of a misdemeanour (in Scotland, of an offence punishable by fine and imprisonment), and shall be liable to forfeit the sum of £100 to any person who will sue for the same, together with costs. Sect. 3 extends the offence (1) to persons who before or during an election shall receive or contract for any money, &c., for voting, or refraining, or agreeing to vote or to refrain from voting; and (2) to persons who, after the election, receive money, &c., on account of any person having voted or refrained, &c. Such persons shall be guilty of a misdemeanour and forfeit £10.

Treating is defined in Sect. 4. Every candidate who gives, procures, or pays for any expenses incurred for meat, drink, or entertainment, or provision to or for any person in order to be elected, or for being elected, or for the purpose of corruptly influencing such person to give or refrain from giving his vote at an election, &c., shall be deemed guilty of treating, and forfeit £50 to any person who shall sue for the same; and every person corruptly accepting such meat, drink, &c., shall be incapable of voting at such election. Persons found guilty of bribery, &c., or from whom penalties as above mentioned have been recovered, shall be struck off the list of voters by the revising barrister. Prosecutions and actions under the Act must be begun within one year. Other sections of the Act prohibit giving cockades to voters at elections, or supplying them with refreshments on account of their having polled or being about to poll. Any candidate for a county, city, or borough found guilty by an election committee of bribery, treating, or undue influence by himself or his agents shall be incapable of being elected or sitting in Parliament for such county, city, or borough, during the Parliament then in existence. Up to 1868 disputed elections were dealt with by committees of the House of Commons, but the Parliamentary Elections Act (31 and 32 Vict. c. 125) has transferred the jurisdiction to Her Majesty's judges (see ELECTIONS). The report of the judge is to have the same effect as the report of an election committee under the old law; and if he reports that corrupt practices have extensively prevailed, a commission of inquiry may be issued under 15 and 16 Vict. c. 57. Candidates reputed by the judge to be guilty of bribery shall be incapable of being elected to the House of Commons for seven years, and during the same period may not (1) be registered as voters; or (2) hold office under 5 and 6 Will. IV. c. 76, or 3 and 4 Vict. c. 108, or any municipal office; or (3) hold any judicial office, or act as justice of the peace. Other persons found guilty of bribery after having had an opportunity of being heard suffer the same disqualifications. Similar provisions against bribery, &c., at municipal elections are contained in the Act 35 and 36 Vict. c. 60.

If the election commissioners, appointed under 15 and 16 Vict. c. 57, report the extensive prevalence of corrupt practices, bills may be brought in for the disfranchisement of the constituency. Bridgewater, Beverley, Sligo, and Cashel were so disfranchised in 1870. Four boroughs—Totnes, Reigate, Great Yarmouth, and Lancaster—were disfranchised by the Representation of the People Act, 1867, for corrupt practices. In the case of a vacancy in a constituency where corrupt practices have prevailed at last election, the House may disfranchise it indefinitely, either by a resolution to that effect or by negativing the motion for a new writ.

The judges manifested great repugnance to the new jurisdiction conferred on them by the Elections Act, and vigorously remonstrated against it during the passage of the measure through Parliament. It was feared that the purity of the bench might be sullied by being brought into close connection with political contests. Public opinion, however, had distinctly condemned the House of Commons Election Committees, which where necessarily anything but judicial in character, and were, besides, tainted with the suspicion of being frequently actuated by political motives. Many petitions have now been tried by the judges, and in a manner which has given great satisfaction to the country. One consequence of the new system which might have been anticipated is the introduction of more precise definitions into the phraseology of election law. "Agency," for example, and "valuable consideration," have been treated by the judges according to the ordinary meaning of the words in courts of law, and candidates have been unseated for the acts of persons, technically their "agents," but personally unknown to them, and for gifts, generally reputed laudable, but legally falling within the definition of bribes. Bribery flourishes most vigorously in the English borough constituencies; and the secret voting introduced by the Ballot Act seems to have had very little effect on the practice, on account of the fidelity with which the corrupt voters keep their promises. In a recent election inquiry before commissioners, witnesses declared their belief that a quarter, or even more, of the constituency was permanently corrupt, and held the balance between the two political parties. Extensive bribery under the guise of charitable distributions of coal, provisions, &c., seems to prevail in many constituencies, and a still more indirect form is the payment of large subscriptions to public purposes. Recently, it has been observed, constituencies have shown a marked preference for wealthy candidates with some local connection.

BRICK, a kind of artificial stone made of baked clay. The usual form of a brick is a parallelopipedon, about 9 inches long, 4½ inches broad, and 3 inches thick. The art of brickmaking dates from very early times. We read that burnt brick was used in building the tower of Babel. The walls and various other buildings of ancient Babylon were made of burnt brick; several varieties of brick figure in Assyrian art, and most of the Assyrian literature was in the form of minute characters in baked clay (see BABYLON, BABYLONIA). Brickmaking formed the chief occupation of the Israelites during their degrading bondage in Egypt. The bricks were made of clay mixed with chopped straw, and were probably sun dried. We read (2 Sam. xii. 31) that David made the children of Ammon pass through the brick kiln; and while the meaning of the statement is doubtful, it is thought that the instruments mentioned in the context may have been used in preparation of the clay. Pliny informs us of three different kinds of bricks made by the Greeks. In Italy we have abundant evidence that the Romans used bricks largely; and it was they, probably, who introduced brickmaking into England. By the time of Henry VIII. the art had reached great perfection; and many fine brick buildings (*e.g.*, the older part of Hampton Court) are extant from that period. Previous to the great fire of 1666, many of the London houses consisted chiefly of timber framework, filled in with lath and plaster; but after the fire, brick was used almost exclusively in building. Much of the brickwork remaining from that time is finely

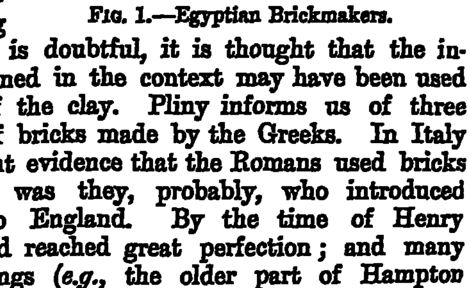

FIG. 1.—Egyptian Brickmakers.

carved with the chisel. From the latter part of last century (1784) till 1850, bricks in this country were subject to taxation. In Holland, where stone is scarce, bricks have been in use from a very early period, both for domestic and public buildings.

c- is The quality of bricks depends primarily on the choice of an earth. There are three principal classes of brick-earths:—(1.) Pure clays, consisting chiefly of alumina and silica, in various proportions, and with a small percentage of other salts, iron, lime, magnesia, &c.; (2.) Loams or sandy clays; (3.) Marls, or earths with a considerable proportion of lime. A paste of pure clay alone (made with water), while it may be easily moulded, will shrink and crack in drying and firing, in proportion to the excess of alumina over silica; but this can be remedied by mixture with a milder earth or with sand. Loams, again, are often so loose that they require the addition of lime as a flux. The London brickmakers add lime and ashes, or *breeze*, to their loams and marls, both as a flux and to prevent shrinking; such admixtures also, as will be seen, affect colour. Brick-earths are very various in composition. The proportion of ingredients in a good earth will be something like the following:—silica, three-fifths; alumina, one-fifth; iron, lime, magnesia, manganese, soda, and potash forming the other one-fifth. The clays of which fire-bricks for furnaces are made are almost entirely free from lime, magnesia, and like substances, which act as fluxes; they are found throughout the coal measures, immediately beneath the coal. The best, that of Stourbridge, will bear the most intense heat that can be produced, without fusion. The Welsh fire-bricks, and those of Windsor, Newcastle, and Glasgow, are other well-known varieties. The Dinas fire-brick consists almost entirely of silica; to this is added about one per cent. of lime, and the mixture, after moulding, is intensely heated. In Austria, a very refractory siliceous brick is manufactured by M. Khern, the chief ingredient being quartz of the highest possible degree of purity.

The colour of bricks is determined by the proportion of hydrated oxide of iron and other ingredients they contain, also by the degree of heat in burning. Where iron is present without lime or such substances, a moderate red heat makes the bricks red, the intensity varying with the proportion of iron; with more intense heat, the bricks, if slightly fusible, may be vitrified externally, and become greenish blue (*e.g.*, the blue bricks of Staffordshire). The presence of lime changes the red colour produced by iron to a cream brown, magnesia also arrests the development of red. Clays burning a pale red will burn yellow if mixed with a fusible white sand, such as is often found on heaths. Some clays, as those of Devonshire and Dorsetshire, burn of a clear white. The London malms give a rich brimstone yellow. The art of ornamental polychrome brick-work has of late years been much developed, especially by the German architects. The principal varieties of common bricks made in England are *place bricks*, *grey and red stocks*, *marl facing bricks*, and *cutting bricks*. The first two are used in ordinary walling. The marl facing bricks, made in the neighbourhood of London, are superior to the stocks, and used in the outsides of buildings. Cutting bricks, which are the finest kind of marl and red bricks, are used in arches over windows and doors.

ick-king. The process of brickmaking varies considerably in different localities. In the following account we shall, in the first instance, confine our attention to methods adopted in the vicinity of London, and thereafter note some of the peculiarities of other systems. The most common mode of preparing the clay, in the London district, is that of *malming*. Among the varieties of brick-earth found there *malm* is a substance that can be used for bricks without any addition. But it is now rare, and an artificial malm is made by mixing chalk and clay, previously reduced to pulp, and allowing the mixture to consolidate by evaporation. Bricks of the best quality are made with this alone; but for the commoner sorts some of the malm is added to the clay or loam, sufficient to make it fit for brick-making.

The earth is dug up in autumn, and placed on a level floor, banked round in order to retain the malm in the process of malming. Exposed during the winter, it is more or less broken up and pulverized by the frost, &c. The machinery for malming consists of two washing-mills, viz., the chalk and clay mills, which are placed together, not far from the brick-earth. The chalk-mill is a circular trough in which chalk is ground in water, by two heavy wheels with spiked tires, drawn round by horses. The pulp thus made passes by a shoot into the clay-mill, another and a larger circular trough, where it gets mixed with clay that is being cut and stirred in water by knives and harrows, also put in motion by horses. The creamy liquid malm passes through a grating into shoots which convey it to the brick-earth, over which it is distributed as equally as possible. It is now left to settle for a month or more, the water being drained off at intervals, till the mass is firm enough to bear a man walking over it. A thin layer of ashes, about 3 inches for every spit of earth, is spread over the surface (this process being technically called *soiling*), and the whole is now ready for the moulding season, which commences generally in April. Malming

The mass of earth, malm, and ashes is first *tempered*, or thoroughly turned over and mixed with the spade, while water is added to give it the proper consistence. The tempered clay is then conveyed to the *pug-mill*,—a conical tub, in which revolves (driven by horses) a vertical shaft with horizontal knives so inclined that the clay is slowly forced down to the narrow end by their motion. Several of these knife-arms are furnished with cross knives, which assist in the cutting and kneading process. The clay comes out laterally at the bottom as a uniform mass, and is ready for moulding.

The moulder stands at a table or stool, on which are placed some of the tempered clay in front of him, a little dry sand to the right and left, a small tub of water with the *strike* in it, a brick-mould, and a stock-board. Backwards from the stool extends the *page*, a pair of iron rails, on wood, on which the raw bricks are pushed away by the moulder. The *brick-mould* is a rectangular case of sheet-iron, without top or bottom, having the two longer sides strengthened with wood. The *stock-board*, supported on four pins in the moulder's stool, fits easily into the mould; it has often a solid elevation in the middle, for producing a hollow in the brick. The moulder receives from the clot-moulder (usually a woman), standing on his right, a piece of clay somewhat larger than a brick. Having sprinkled sand on the stock-board, and dashed the mould, after moistening it, in the left sand heap, he places the mould on the stock-board, and dashes the clay into it with force, then pressing it with his fingers so as to fill the angles. With the *strike* (a short, smooth piece of wood) he strikes off the surplus clay; then he turns the brick out of the mould on a thin board or *pallet*, rather larger than the brick, and slides it along the page to the taking-off boy, who stands ready to put the bricks on a barrow of special construction; on this, after sprinkling with sand, they are conveyed to the hack ground. The bricks are each carefully removed from the barrow between two pallets, and built up in *hacks*, about eight bricks high, and two in width (placed edgewise, and in an angular direction,—the hacks being about 11 feet apart, from centre to centre. They are covered with straw or reeds at night or in bad weather. When half dry the bricks are separated somewhat (*scintled*), to allow Moulding

free access of the air. The time taken in drying varies from three to six weeks.

rning. In the vicinity of London bricks are commonly burnt in *clamps;* the peculiarity of which process is that, as each brick contains in itself the fuel necessary for its vitrification, the *breeze* merely serves to ignite the lower tiers, and the heat gradually spreads over the whole. The general structure of a clamp is as follows :—A number of walls, or *necks*, three bricks thick, about sixty long, and twenty-four to thirty high, are built slantingly against a central upright wall, which narrows upwards. The sides and top are cased with burnt bricks. Cinders (or *breeze*) are distributed in layers between the courses of brick, the thickest strata being at the bottom. A single clamp will contain from 200,000 to 500,000 bricks. For firing the clamps, *live holes* or flues (9 inches by 7) are left in the centre of the upright, and at every seventh neck or so, extending throughout the thickness of the clamp. These are filled with faggots, and fired by a coal fire at the end of each vent; and the fire ignites the adjacent breeze. Once the clamp is fairly lighted, the mouths of the live holes are stopped with bricks and plastered over with clay, and the clamp burns till all the breeze is consumed, usually from three to six weeks. After cooling, the bricks are removed, sorted, perhaps, and stacked. (For a fuller account of the most approved methods of building clamps, the reader is referred to Mr Dobson's excellent little treatise on brick-making, to which we are indebted for many of the details given in this paper.)

ttingham. In the Nottingham district a very hard marl is often used in brickmaking; and as ordinary weathering and tempering would not make it sufficiently plastic, it is subjected to grinding between rollers, the hard lumps and pieces of limestone being thus crushed to powder, all pebbles and hard stones having been previously picked out by the hand. The wash-mill is only used in making arch-bricks, and the pug-mill is dispensed with, the tempering of the clay, after grinding, being done by treading and spade labour. Sometimes the clay is kept in damp cellars for a year or more to ripen. Brass moulds (technically called copper moulds) are used, and the moulder, after filling the mould, works over the clay, first on one side then on the other, with a flat implement called the *plane*. A boy takes the mould with its contents to the floor, where he turns out the brick, and then puts back the mould on the stool, the moulder meanwhile filling another mould. The bricks are sprinkled with sand on the floors, and turned twice at a few hours' interval, and are then taken by boys to the *hovel* or drying-shed, when they are built in hacks. They are burnt in kilns, which are made with four upright walls and a sunken floor. On the two sides of the kiln there are shallow pits with lean-to roofs to protect the fuel and fireman. The doorways are narrow openings at the ends, a step above the ground, and the fire-holes are arched openings opposite each other in the side of the kiln, lined with fire-bricks. Narrow openings or flues are left between the bricks, connecting the opposite fire-holes. Each brick has some free space round it for passage of heat. The fuel employed is coal.

tafford-hire. In the Staffordshire Potteries it is a common practice to pass the marl through several pairs of rollers, and then mix some three or four marls together, with water, by spade labour. For ordinary bricks the ground marl is mixed with marl that has been tempered but not ground. The pug-mill is employed for tiles and dust bricks,—the latter so called from coal dust being used when they are moulded. The bricks are moulded by the *slop-moulding* process, the mould being dipped in water only before using; the brick is emptied from the mould on the floor. (The other process is distinguished as that of *sand-stock moulding.*) The oven used in burning is of circular form, with spherical top, and will contain about 8000 bricks. Red, blue, and drab bricks are produced in the district, besides the dust brick just referred to, which is used for the paving of footways..

In Holland, the chief material used for bricks is the slime deposited in rivers and arms of the sea. It is collected in boats by men with long poles, having a cutting circle of iron at the end, and a bag net with which they lug up the slime. Hard bricks are made of a mixture of this slime with sand from the banks of the River Maas. The ingredients are well kneaded together, and the mixture is deposited in heaps. The mode of moulding and drying is similar to that used elsewhere. The kilns are square and will sometimes hold as many as 1,200,000 bricks. Peat turf is used in firing. Hollan

For an account of brickmaking in India the reader is referred to a paper by Major Falconnet, R.E., in the *Professional Papers on Indian Engineering*, May 1874.

Thus far only brickmaking by hand has been spoken of, but of recent years there has been no little activity in the invention of brickmaking machines, with a view to economy, certainty, and rapidity of production, and improvement in the quality and appearance of the bricks. It is only in brickmaking on a considerable scale, of course, that moulding by machinery can present much advantage over hand moulding, since the cost of moulding bears so small a proportion to the total cost. The various machines that have been offered to the public may be arranged in two classes,—those which operate on the clay (with moderate pressure) in a moist and plastic state, and those in which the material used is pulverized and dry, or nearly so. A denser brick, and one less liable to shrinking, is produced in the latter case; but much care is needed in preparation of the clay, and a much stronger compression is required, to ensure the proper tenacity. The different arrangements of rollers and pug-mills for *preparation* of the clay, whether plastic or dry, we need not here describe at any length. Rollers and pug-mill are sometimes combined, forming a composite machine. Two or more pairs of rollers are sometimes arranged one set under another, the closest at the bottom; and opposing rollers are driven at different speeds so as to produce a rub as well as a squeeze, thus promoting disintegration. As to that class of brickmaking machines proper in which plastic clay is used, we find, in some examples, a continuous length of clay forced out from a vertical or horizontal pug-mill through a suitable mouth-piece, and the column divided into bricks by wires or otherwise. Of mouthpieces, some are simple dies, or dies fitted with cores to make hollow bricks; in others the mould is lubricated by a constant stream of water; in others, again, the mouthpiece is made with two or four rollers covered with thick cloth, which are perforated with small holes, and filled with oil to lubricate the faces of the bricks. In cutting, a frame of parallel wires may be moved across, either while the clay is at rest, or while it is in motion, by the wires being moved obliquely at an angle to compensate for the speed at which the clay travels. Or the clay may be cut by radial wires of a wheel, or again by metallic discs. Another variety of treatment of plastic clay is that in which the clay is pressed from the pug-mill into moulds of the form of brick required. In one such machine, a mould-block, with two moulds, moves backwards and forwards under the pug-mill, one mould receiving a charge while the other is having the brick pressed out of it by a piston. In another, the moulds are arranged radially round the border of a circular table, which revolves under the pug-mill. There are piston rods in the mould which ascend an inclined spiral plane, and thus gradually lift the bricks out of the moulds, whence they are taken by a boy and placed on an endless band, which conveys them Brick-making machin

away. In another machine, also with revolving table, two moulds receive the charge of clay at once. While these are being filled the two that had just been filled are being subjected to considerable pressure, and the two bricks that had been pressed immediately before are in process of delivery out of the moulds, and on to a flat belt which takes them away. (This machine is also suitable for dry clay.) In yet another, a cylinder revolving under the pug-mill presents to it successively four brick-moulds, each of which, on reaching the lowest point, is made to deposit its brick on an endless band. The annexed drawing represents one of Messrs H. Clayton, Son, & Howlett's single delivery machines for brickmaking with plastic clay. After what has been said little description will be necessary. A is the pair of rollers, B the pug-mill, C the stream of issuing clay, which a little further on is cut across by

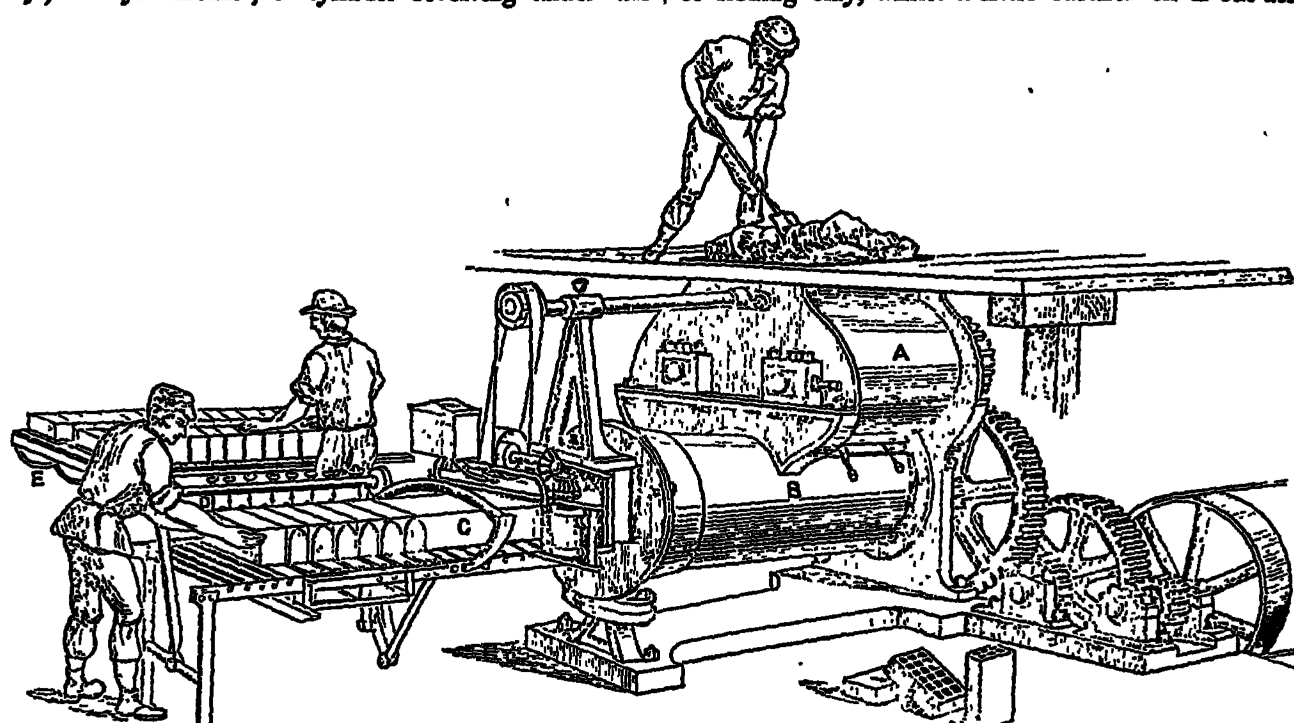

FIG. 2.—Brickmaking Machine for Plastic Clay.

means of the wire frame D. The bricks are then removed to the barrow E. These machines are often constructed for double delivery.

As an example of the second class of machines,—those for working dry, or half-dry, and non-plastic material,—we may take another machine constructed by Messrs Clayton. It affords a good practical solution of the problem of making bricks from coal shale, bind, fire-clay, or the like. The arrangement is shown in figs. 3 and 4. In fig. 3, A

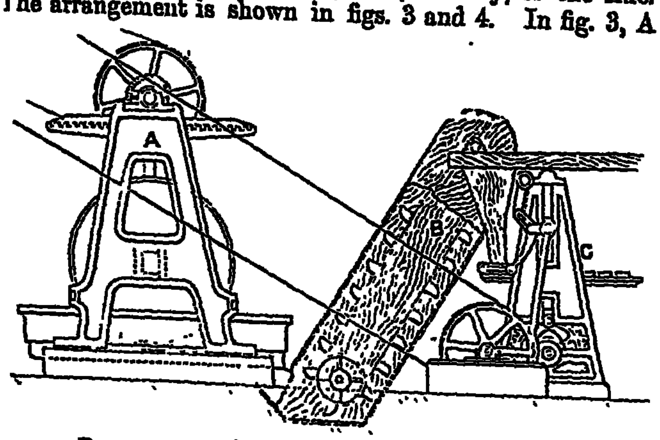

FIG. 3.—Section of Machine for Non-plastic Material.

is a pan roller mill, in which a pan containing the raw material is driven round under rollers; there are perforations in the bottom, through which the ground clay escapes, and is swept by arms into a general receiver, whence a band with buckets conveys it to the hopper of the moulding and pressing machines C, of which fig. 4 gives another view. Here the moulds are contained in a box at B, bolted between the standards. There are two sets of pistons, one above and the other below the brick-moulds, and they simultaneously press the top and the bottom of the brick in the mould. The lower pistons are attached to a cross bar which slides in vertical guides in the standards, and has friction rollers C on the lower extremities, in contact with which work two pressing cams D on the main shaft. The upper pistons E are attached as shown to a cross-head above, which is moved up and down in its guides by connecting rods and two cranks on the main

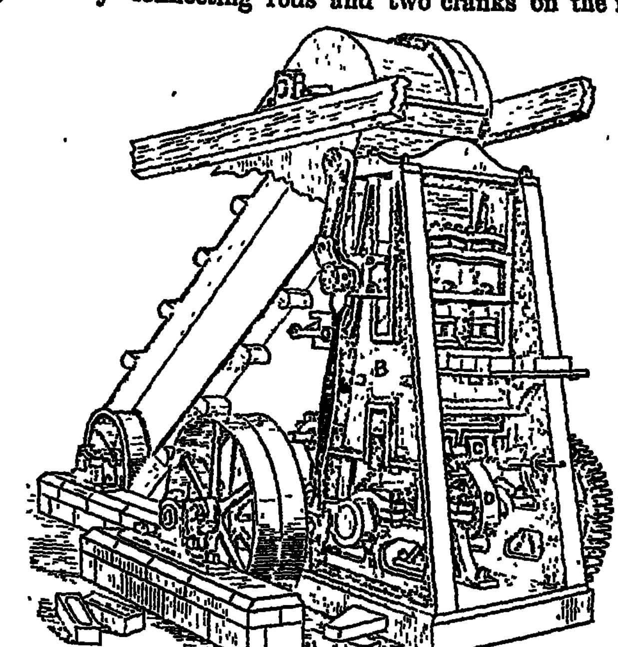

FIG. 4.—Part of Machine shown in section in fig. 3.

shaft. These pistons are hollow, and are heated by steam to prevent the brick-earth adhering to them. The prepared material is supplied to the two moulds by a feed-box which slides to and fro under the feeding hopper of the machine.

and thus passes alternately under it and over the moulds, conveying sufficient each time to fill the latter. The bricks are delivered from the moulds by the lower pistons, which are forced upwards by the complete revolution of the cams, and the newly-made bricks are forthwith moved forward by the approach of the feed-box with a fresh charge of the material. In another dry-clay machine constructed by Messrs Bradley and Craven of Wakefield, two or three distinct pressures can be given to a brick, and by this means the air is gradually forced out from the interstices, and the brick consolidated to a greater extent than can be effected by a single pressure.

The varieties of brickmaking machinery are too numerous to be separately noticed, however briefly, but the foregoing may suffice to illustrate the general principles involved in their construction. With suitable modifications, perforated or hollow bricks are frequently produced, on which there is a saving in cost of carriage, and also in mortar and labour.

'nburnt ricks. Among the objects at the International Exhibition of 1874 there were several varieties of brick prepared without burning, according to a process devised by Messrs Bodmer. They are made by intimately mixing certain materials of the nature of cements or mortars, and squeezing the mixture into the desired shape by hydraulic pressure in a specially-constructed machine. Sand and selenitic lime are the constituents of one kind of brick; these substances, together with Portland cement, of another; and a very serviceable kind of brick is prepared from blast-furnace slag, which, consisting chiefly of silicates decomposable by lime, is just as suitable for the purpose as the volcanic products, trass and pozzuolano, which have long been employed. The bricks give good results on application of the usual tests.

'loating ricks. The old invention of *floating bricks* (known to Pliny) was completely lost till M. Fabroni discovered they could be made from the earth known as fossil meal, which is abundant in Tuscany, and is found near Castel del Piano in the territories of Siena.

Ioffmann's ilns. For the drying and burning of bricks, the construction of kilns according to Hoffmann's method is a remarkable improvement of late years. These kilns are formed by a series of arched chambers connected by passages to one main chimney flue, each passage or flue having suitable dampers to regulate the heat at any desired point. Small coal, slack, or peat fuel may be used, which is fed in from the top of the kilns through small openings. The waste gases from the burning and cooling chambers are made to pass successively into other chambers and give out their heat before escaping to the chimney, thus completing the drying, and effecting a partial burning, of newly-made bricks before the actual firing of the chambers in which these latter are newly set. Such kilns are no doubt beyond the means of most brickmakers, but it is perhaps a question for consideration whether bricks must necessarily be burnt in immediate proximity to the spot where the clay is obtained.

In an instructive report on the manufacture of bricks, drawn up a few years ago by a committee of the Manchester Society of Architects, the following points were specified as requiring attention, in order to improve the character of the common brick:—(*a*) Greater care in cleaning the clay and in thoroughly tempering it; (*b*) variation in the size of moulds, so as to produce uniform sized bricks from various clays; (*c*) moulding the brick with material of such consistency that it may not become misshapen by the effects of its own gravity; (*d*) greater regularity of surface of the drying-ground; (*e*) protection from extreme variations of temperature and rain in drying; (*f*) less frequent and more careful handling in the process of drying, so as to preserve the edges; (*g*) a means of burning whereby the amount of firing shall be under control. In experiments on the absorption and retention of moisture, it was found that the bricks which parted most readily with their moisture at first were the longest in drying, and *vice versa*.

Tiles, being a thinner ware than bricks, have to be made of purer and stronger clay, and require more care in treatment; but the process of manufacture is not essentially different. The numerous varieties of tiles may be roughly arranged in three classes, viz., *paving tiles*, *roofing tiles* (including the flat plain tiles, the curved pantiles, hip, ridge, and valley tiles), and *drain tiles*. In weathering, the clay is spread in layers of about 2 inches thickness during winter, and each layer is allowed the benefit of at least one night's frost before the succeeding layer is put upon it. Sometimes the weathering is effected by sunshine. The comminuted clay is next placed in pits and allowed to mellow or ripen under water. Then it is passed through the pug-mill, and the tempered product, if necessary, *slung* (that is, cut in thin slices with a piece of wire fixed to two handles, in order to detect any stones), and then passed through the pug-mill again, after which it is generally ready for moulding. To take the case of *pantiles* (hand-moulded), the moulder turns the tile out of the flat mould on to the *washing-off frame*, on the curved surface of which, with very wet hands, he washes it into a curved shape. Then he strikes it with a semi-cylindrical implement called the *splayer*, and conveys it on this to the flat block where he deposits it, with the convex side uppermost, and, removing the splayer, leaves the tile to dry. The tile is afterwards beaten on the *thwacking-frame*, to correct any warping that may have occurred, and trimmed with the *thwacking-knife*. In the kiln, which is constructed with arched furnaces at the base of a conical erection called the dome, the tiles are closely stacked in upright position, on a bottom of vitrified bricks. The fuel used is coal, and the burning continues usually about six days. In making *pipe drain tiles*, the clay is first moulded to the proper length, width, and thickness, then wrapped round a drum; the edges are closed together, and the tile is carefully shaped by the operator's hand, sometimes assisted by a wooden tool. Tiles as well as bricks can be made by machinery; with suitable dies, almost any form of tile may be thus had, which is producible by the advance of a given section of clay parallel to itself. In other machines pressure is exerted on the clay in a mould. Tiles.

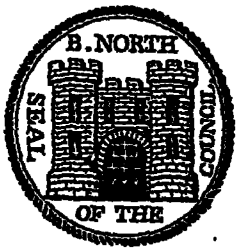
The manufacture of *tesseræ* and *encaustic tiles* has been brought to great perfection in recent times, through the enterprise especially of Mr Minton. It is a revival and extension of a very old art, which originated, probably, with the Greeks. The tesselated pavements of the Romans, of which many specimens are still extant, were formed of small pieces of stone or marble of various colours, bedded one by one in a layer of cement. The principle on which tesseræ are now made, is that dry and finely-powdered clay, compressed between steel dies, is changed into a very compact and hard solid body, a fact first observed by Mr Prosser in 1840. The solid pieces, which are thus produced in a screw-press, are enclosed in earthenware cases or pans, call *saggers*, and fired in a potter's kiln, after which they are ready for use, unless they are required to be glazed, in which case they are dipped in a glazing composition and again fired. The mode of setting the pieces differs essentially from the Roman method. In manufacture of the tiles called *encaustic*, in which various designs are produced by addition of clays of different colour from that of the ground, the clays first undergo sundry washings and purifications. A portion of the kind which is to form the ground first receives an impression, in the plastic state, from a plaster in relief. The bulk of the tile is made up Encaust tiles.

with coarser clay added in a frame, and this is solidified in a screw-press. Then comes the filling in of the design, which the maker does by spreading the coloured clay in a creamy or slip state on the indented surface. After a few days' evaporation, the surface is scraped or planed, and the tile passes successively to the drying house and the oven. The colours desired in encaustic tiles are sometimes those given by the clay in ordinary treatment, sometimes they are obtained by staining with manganese, cobalt, &c. The products of this branch of manufacture are much admired.

The fine ornamental bricks of various shape and colour known as *terra cotta* have of late been much used, especially in the facing of public buildings, and with the happiest effects. (A. B. M.)

BRIDAINE, JACQUES, a celebrated French preacher and home-missionary, was born in 1701 at Chuslan in the department of Gard. Though a rigid Catholic in principle, he gained the good-will of the Protestants of France by the boldness with which he advocated their cause on many occasions, and the personal kindness which he displayed towards many of their number during the persecutions to which they were exposed under the Regent Orléans and Louis XV. He accomplished no fewer than 250 evangelizing journeys through various parts of France, in the course of which he made himself universally popular, being possessed of a powerful though rugged eloquence. He was the author of a collection of *Cantiques Spirituels*, which has been frequently reprinted, and of five volumes of sermons, printed at Avignon in 1825. In the neighbourhood of this town he died in 1767.

BRIDGENORTH, a parliamentary and municipal borough and market town of England, in the county of Shropshire, on both sides of the Severn, 18 miles S.E. by E. of Shrewsbury. The river, which is here crossed by a handsome stone bridge of six arches, separates the upper from the lower town. The former is built on the acclivities and summit of a rock which rises abruptly from the river to the height of 180 feet, and gives the town a very picturesque appearance. The railway passes under by a long tunnel. On the summit is the tower of the old castle, leaning about 17 degrees from the perpendicular; two parish churches, one of which, St Leonard's, was rebuilt in 1862; and a large public reservoir. There are in the town a mechanics' institute, a public library—founded by the Rev. Mr Stackhouse, an infirmary, a jail, a theatre (1824), a market hall (1855), and a considerable number of schools and charities. It has manufactures of carpets, worsted, and tobacco-pipes, and some trade in agricultural produce. It returns one member to parliament. The population of the parliamentary borough amounted in 1871 to 7317; that of the municipal borough to 5876.



Arms of Bridgenorth.

Bridgenorth, or Brigge, is said to have been founded by Ethelfleda, the daughter of Alfred, and it was fortified with a castle and walls by Robert de Belesme, earl of Shrewsbury. On the earl's rebellion the town was besieged and taken by Henry I. in 1102; and in the reign of Henry II. the castle was dismantled. In 1646 the town, being held by a Royal garrison, sustained a remarkable siege by the Parliamentary forces, who at last obtained possession.

BRIDGEPORT, a seaport town in the county of Fairfield, Connecticut, United States, is situated on an arm of Long Island Sound, 58 miles N.E. of New York, in 41° 10′ N. lat. and 73° 11′ W. long. It has several iron-foundries and manufactures fire-arms, metallic cartridges, sewing-machines, carriages, harness, locks, blinds, &c. The coasting trade and the fisheries are both extensive. The bar at the mouth of the harbour, which is formed by the Pequonnock Creek, has 13 feet at high water. Bridgeport is the centre of an extensive system of railways, and steamboats ply between it and New York. The township was separated from Stratford in 1821, and the city, formerly called Newfield, was incorporated in 1836. Population in 1870, 19,835.

BRIDGES

§ 1. *Definitions and General Considerations.*—Bridges are structures designed to carry roads across streams, gullies, or roads. A viaduct may be distinguished from a bridge, inasmuch as the object of the former is to carry a road at a considerable elevation above the surrounding country, by means of structures, similar indeed to bridges, but in which the object of the open spans is to save expense rather than to cross some obstacle which could not be passed by a level road or embankment. The aqueduct is a structure similar to the viaduct, but employed to convey or support water. A culvert may be distinguished from a bridge as an opening, the primary object of which is to let water flow past a road or other obstacle, the object being similar to that of a large drain. A large culvert might be called a small bridge, and a bridge having long approaches with many spans might be called a viaduct. The present article will treat only of Bridges.

Every bridge may be divided into two parts, the *substructure* and the *superstructure*. The substructure of a bridge consists of foundations, abutments, and piers. The end supports of the bridge are the abutments, and the intermediate supports are called piers. Piers and abutments rest on foundations in the ground. A bridge of one span has no piers. The superstructure of a bridge consists of the roadway and the beam, arch, or chain used to carry the roadway from support to support.

The dimensions and design of a bridge depend on the nature of the obstacle to be crossed and on the traffic to which the road over the bridge is subject. The engineer is usually bound to design the cheapest structure which will perform the required duties; he has, therefore, in each case to consider whether a small number of large spans or a large number of small spans will be cheaper. Large spans will be desirable where foundations cannot be easily obtained, or where the height of the structure is great. The engineer has also to determine whether, considering the prices of materials, labour, and transport, one or other form of super structure is to be preferred. The traffic to be accommodated will determine the width of the bridge and the load which the superstructure must bear. In many cases it will also be the duty of the designer to endeavour to combine beauty with utility. Beauty does not require ornament or expense, but demands, what may be more difficult to supply, correct taste in the designer.

In Great Britain law prescribes the following minimum dimensions for the over and under bridges of railways. (An *over bridge* is one in which the road goes over the railway; an *under bridge* one in which the road goes under the railway.) *Over bridges.*—Width: turnpike road, 35 feet; other public carriage road, 25 feet; private road, 12 feet. Span over two lines (narrow gauge), generally about 26 feet; head room, 14 feet 6 inches above outer rail. *Under bridges.*—Spans: turnpike road, 35 feet; other public carriage road, 25 feet; private road, 12 feet. Head-room: turnpike road, 12 feet at springing of arch, and 16 feet throughout a breadth of 12 feet in the middle; for

public road, 12 feet, 15 feet, and 10 feet in the same places; private road, 14 feet for 9 feet in the middle; for exceptions the Acts must be consulted. In designing a bridge to cross a stream care must be taken to insure that the openings are suitable for the maximum floods.

The *load* which the superstructure of a bridge has to carry in addition to its own mass may be estimated as follows:—

1. For a *public road;* one hundredweight per square foot will represent the weight of a very dense crowd. This is greater than any load which ordinary carts or vans will bring on the bridge, but of late years traction engines and road rollers have been introduced, and a weight of perhaps 10 tons on each wheel on one line across the bridge ought in future designs to be provided for. The bridge must be strong enough to bear this maximum weight applied at any point, and also to bear all possible distributions of the crowd. A bridge might be fit to carry the crowd uniformly distributed over its surface, and yet fail when the crowd covered one-half of its length or width.

2. For a *railway;* the maximum passing load on each line of rails may be taken as the weight of a train composed exclusively of locomotives. The bridge must be fit to bear this load distributed in all possible ways along the line. For spans above 60 feet on the usual 4 feet $8\frac{1}{2}$ inches gauge this load may generally be taken as equivalent to 1 ton for each foot in length of each line of way, or in engineering language, "one ton per foot run." Where a very heavy class of locomotives is in use $1\frac{1}{2}$ tons per foot run must be provided for. For small spans the distribution of the load as a locomotive passes is such that the above allowance is barely sufficient. For very small spans of 8 or 10 feet the maximum passing load is a little more than the weight on the driving axle of the locomotive, or say 14 tons.

§ 2. *Classification.*—Bridges are classed, according to the design of their superstructure, as *girders, arches,* and *suspension bridges.* A beam of wood crossing a stream, a brick arch, and a platform hung to a flexible wire rope are common examples of the three types. The essential distinction between the three types may be said to be, that in all forms of the suspension bridge the supporting structure (*i.e.*, the wire rope in the above example) is *extended* by the stress due to the load; in all forms of the arch the supporting structure (*i.e.*, the ring of bricks in the above example) is *compressed* by the stress due to the load; and in all forms of the beam or girder the material is partly extended and partly compressed by the flexure which it undergoes as it bends under the load,—thus when a beam of wood carrying a load bends, the upper side of the beam is thereby shortened and the fibres compressed, while the lower side of the beam is lengthened and the fibres extended.

Beams or *Girders* may be of various materials,—wrought iron, cast-iron, and wood being chiefly employed.

Arches may be of masonry, or they may be of wrought or cast iron or steel, in which case the compressed sector of a ring is usually a continuous and stiff structure.

Suspension bridges are made of wire ropes or of separate links of wrought iron or steel pinned together so as to form a chain. The metal beam, arch, or suspension bridge may be a continuous structure or an open frame; we shall also find that in some designs the several simple types are combined so as almost to defy classification.

Whatever design be adopted, the strength or efficiency to carry a given load depends on similar considerations. The designer selects that form of superstructure which the principles of statics show to be most desirable; he calculates the maximum stress which the load can produce on each part, and then so distributes his material that the maximum intensity of stress on every part shall be a definite fraction of the ultimate strength of the material. In metal structures, where the above principle can be very perfectly carried out, this fraction varies from one-sixth to one-third, according to the certainty with which the stresses and strength of the materials are known. In stone structures the engineer has greater difficulty in calculating the stresses on each part, and relies more on empirical rules based on long experience.

I. Strength and other Properties of Materials employed in Bridges.

§ 3. *Classes of Stress.*—There are three kinds of stress, due to tension, compression, and shearing. Tension tends to cause failure by the extension or lengthening of the part strained; compression tends to cause failure by the crushing of the part strained; and shearing stress tends to cause failure by the sliding of one part of the piece across the other from which it is shorn off.

§ 4. *Tenacity, or Strength to resist Tension.*—When tension is applied to a rod or link of any material so as to be resisted equally by each element of any imaginary section in a plane normal to the direction of the pull, this section, which is called a *cross section,* is said to be subject to a stress of *uniform intensity.* This intensity p is equal to the quotient of the whole pull P divided by the area S of the cross section, or

$$1. \quad . \quad . \quad . \quad . \quad . \quad . \quad p=\frac{P}{S}.$$

The ultimate strength of a rod subject to uniform stress is proportional to the section S, and the ultimate strength of the material is measured by the maximum intensity of stress which it can bear, or in other words, by the stress which the unit area of cross section can bear; for example, if the unit of force employed be the weight of a ton, and the unit of area the square inch, the strength of materials will be measured in tons per square inch, or by the number of tons which will just tear asunder a rod one inch square, great care being taken that the load is so hung on the rod as to bear equally on all parts of the cross section.

The following table gives in tons or lbs. per square inch the ultimate strength f_t of some of the materials used in bridges:—

Table I.—*Tensile Strength of Materials* $= f_t$.

Name of Material.	Tons per sq. inch.
Wrought Iron Plates	20 to 25
" " Bars and Bolts	25 to 30
" " Wire	30 to 45
Steel Plates	30 to 40
Steel Rivets	41 to 48
Steel Wire	50 to 100
Cast-iron	6 to 8
Red Pine	5·1 to 6·3
Larch	4 to 5·5
Oak	4·5 to 8·5
Teak	6 to 9
	Lbs. per sq. inch.
Brick (specimens of)	250 to 300
Basalt "	1000
Sandstone "	285
Common Mortar	10 to 50
Hydraulic Mortar	85 to 140
Roman Cement, 12 months old	46
Portland Cement, 7 days old	270
" " 12 months old	350 to 470

The ultimate strength P_1 of a bar with the cross section S to resist a stress uniformly distributed over that section is given in terms of f_t by the expression—

$$2. \quad . \quad . \quad . \quad . \quad . \quad . \quad P_1=Sf_t.$$

Table I. gives some idea of the tensile strength of the materials, but for a full comprehension of the subject special treatises, or the article on the Strength of Materials,

must be consulted. No two specimens of any material ever give exactly similar results. The various brands of iron differ much; different specimens of steel differ still more; the strength is greater when the stress is applied along than when it is applied across the fibres. Iron or steel forged or drawn *down to a small cross section* is stronger than when in large masses; the material in small castings is stronger than in large castings run from the same batch of metal; the skin is stronger than the rest of a casting. The variations to be expected in timber are still greater than those in metals, and the values for stones or bricks must in each case be specially determined by experiment on the special kind to be used. These warnings are applicable to the subsequent tables, which give the strength of materials to resist other kinds of stress.

§ 5. *Strength to resist Crushing.*—The law given for tension applies to the compression of blocks, so that the strength f_c of a material to resist crushing may also be measured in tons per square inch. Thus the ultimate strength P_1 of a block of the cross section S, subject to a uniform stress, is given in terms of f_c the strength of the material per unit of section by the expression—

1. . . . . . . $P_1 = Sf_c$.

This equation is not applicable to blocks or struts of iron in which the ratio of the shortest side of the cross section to the length is less than about 1 to 5, nor to struts of timber in which this ratio is less than about 1 to 10. When this limit is passed the strut bends before failing (*vide* § 57), and whenever this occurs the essential condition that the stress shall be uniformly distributed no longer obtains. The flexure increases the stress on the inside of the curve assumed by the strut or pillar, and diminishes it on the outside; but the strut will fail as soon as *any part* of the cross section is subject to a crushing stress of greater intensity than f_c.

TABLE II.—*Ultimate Strength to resist Crushing* $= f_c$.

Name of Material.	Tons per sq. inch.
Wrought Iron	15 to 18
Cast-iron	37 to 65
Steel Plates	90
Red Pine	2·4 to 2·76
Larch	2·5
Oak	2·7 to 4·5
Teak	5·4
Bricks—	
	Lbs. per sq. inch.

Chalk	330 to 500
Béton	420 to 580

§ 6. *Strength to resist Shearing.*—Let a bar AD of any material be firmly supported on C, as shown in fig 1, and let a strong tool B, say of steel, descend upon it in the direction of the arrow, with force sufficient to sever the part D from the part A, so that the surface dividing the two parts is in the plane of the face of C. This tool is said to *shear* the bar, and the resistance which the bar opposes to this stress is called its strength to resist shearing. The tools practically used to shear are not quite square at the edge, and therefore *cut* slightly, but for true shearing the lower face ought to be square, and the tool should come down close

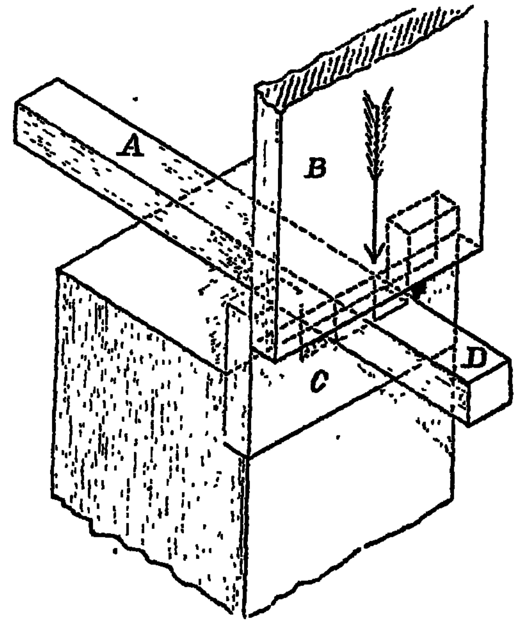

Fig. 1.

to the support, so that the inner face of the tool slides on the outer face of the support.

Fig 2. represents two iron links joined by an iron pin. If the links are pulled asunder the pin will be shorn

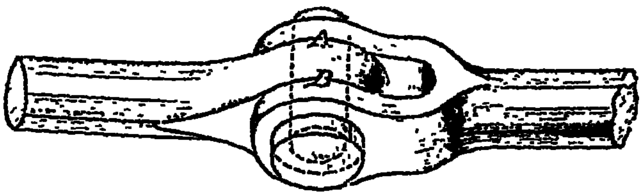

Fig. 2.

at two places, A and B, and the whole section shorn will be twice the cross section of the pin.

Fig 3 shows a joint where the pin would be shorn in four places—A, B, C, and D.

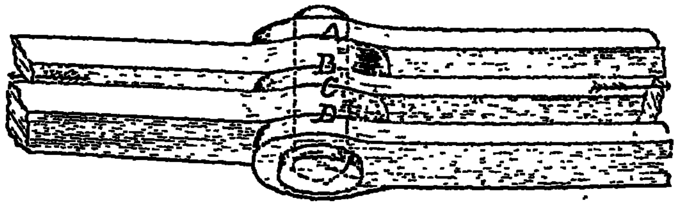

Fig. 3.

The strength of a piece of any material to resist shearing is usually assumed by engineers to be proportional to the cross section to be shorn through, and each material may consequently be said to have a certain shearing strength per square inch; in other words, the ultimate shearing strength of the material is the *intensity* of stress required to shear it asunder. If, therefore, P_1 be the ultimate strength of a bar of cross section S to resist shearing in n places, and if f_s be the ultimate strength of the material, we have the expression—

1. . . . . . . $P_1 = nSf_s$.

The assumption on which this equation is founded is not strictly correct; indeed, the actual shearing described does not correspond with any simple homogeneous stress, and the form of the cross section shorn through must exercise considerable influence on the strength of the piece to resist shearing. In a round pin the maximum intensity of shearing stress is $\frac{4}{3}$ of the mean intensity, and in a rect-

angular pin $\frac{3}{8}$ of the mean intensity. See STRENGTH OF MATERIALS.

The pins which join the links of suspension bridges, and the rivets which join the wrought iron plates of girder bridges, are subject to shearing stress, and the area to be shorn through must be made sufficient to bear the total shearing stress on that part of the structure. Wood is strong to resist tension, and would be much employed for ties but for the difficulty of taking hold of the ends of the tie in such a way that these ends shall not fail by being shorn.

Fig 4 shows the end of a balk of wood with a strap bolted to it. This strap would be torn off by the shearing

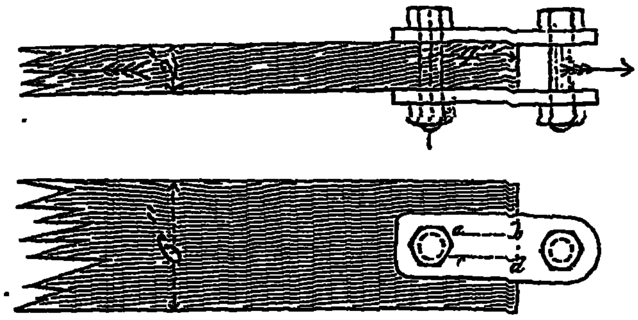

Fig. 4.

of the wood along the dotted lines *ab* and *cd*, with a stress which would be much less than that required to overcome the tenacity of the wood; for if the dimensions of the balk of pine are 6 in. by 2 in. with an inch hole, its tensile strength will be 10 × 5 or 50 tons, while if the bolt be 1 inch diameter, and be placed 4 inches from one end, it could be torn out by shearing 16 inches of the wood; now each inch will only resist a shearing stress of say 600 ℔, so that the bolt would be torn out with only 4·3 tons. Thus at least eleven such bolts, each 4 inches from its neighbour, and occupying 3 feet 8 inches in length of this balk, with an iron strap of corresponding length, would be required to render the full strength of the balk as a tie available. A similar difficulty is met with when timber is joined, as in fig. 5, where shearing would take place along the dotted lines AB or CD.

Fig. 5.

TABLE III.—*Ultimate Strength to resist Shearing* = *f*.

Name of Material.	Tons per sq. inch.
Cast-iron	14·5
Wrought Iron	22
Steel Rivets	30 to 36
Red Pine	·22 to ·35
Larch	·43 to ·75
Oak (British)	1

The strengths given here for wood are those obtained by testing the resistance to shearing along the grain.

The strength of wrought iron to resist shearing may be taken as practically equal to its strength to resist tension—an assumption which facilitates the design of rivetted and other joints.

The strength of steel to resist shearing is less than its strength to resist tearing in the ratio of three to four approximately. Rivets employed to joint steel plates require, therefore, to be larger or more numerous than those employed for iron plates of equal dimensions.

§ 7. *Elasticity.*—When a piece of any material is under tension or compression, it is lengthened or shortened by the stress, and the amount of extension or compression for the same length and stress varies with different materials. Approximately correct results are obtained by assuming that the extension or compression of a given piece of the material of uniform cross section, under a uniformly distributed stress constant throughout its length, is proportional to the length of the piece and to the intensity of the stress.

Let p be the intensity of the stress in tons per square inch, let l be the length of a specimen of a given material in any unit, and let e be the extension or compression observed in the same unit. Then the expression $\frac{pl}{e}$ is, on the above assumption, a constant quantity, and this ratio is experimentally found for many materials to be sensibly constant for stresses which do not approach the ultimate strength. This constant ratio E has received the name of modulus of elasticity, and is generally expressed in tons per square inch, this being the unit in which p is measured. Thomson and Tait (*Elements of Nat. Phil.*) call E the "measure of longitudinal rigidity," a better name than the modulus of elasticity. The actual extension or compression e of any piece of a structure is given by the expression—

$$1. \quad \ldots \ldots \quad e = \frac{pl}{E},$$

where p is in tons per square inch; e will be given in terms of the unit in which l is expressed.

TABLE IV.—*Modulus of Elasticity* = E.

Name of Material	Tons per sq. inch.	Name of Material.	Tons per sq. inch.
Wrought Iron	10,000 to 13,000	Slate	5800 to 7100
Iron Wire	11,500	Red Pine	650 to 850
Wire Ropes	6700	Larch	400 to 600
Steel Bars	13,000 to 19,000	Oak	585 to 780
Cast-iron	5250 to 10,000	Teak	1070

The modulus of elasticity is very generally assumed as equal for extension and compression, which is nearly true for wrought iron and steel under any stress to which these materials can be safely subjected. The principle of continuity shows that there can be no difference in the value of E for positive and negative stresses so long as these are small. The law according to which E varies as p changes is not accurately known for any material. When the stress is small the value of E appears to be more nearly constant in wrought iron than in cast-iron, but the change in the value of E corresponding to a change from a small stress to the ultimate stress is greater in wrought iron than in cast-iron. The values in the table cannot be depended upon to give very exact results, as the elasticity of different specimens of the same material varies considerably; the theory is wholly inapplicable when the breaking strain is approached; the engineer, however, seldom requires to calculate the extensions or compressions when the stress is even so great as one-third of the ultimate strength. For the same reason the engineer need seldom take account of the permanent set caused by stresses exceeding those within which the material may be considered perfectly elastic. B. D. Stoney, in his work on the theory of strains on girders, gives an excellent summary of what is known experimentally concerning *set* and the modulus of elasticity.

§ 8. *Strength to resist Tension or Crushing when the Stress is not Axial.*—When the resultant of a stress passes through the centre of surface of the cross section of the piece of a structure, and is normal to the cross section, the stress is called *axial*, and it is usually assumed that this stress will be borne uniformly by all the elements into which the surface of the cross section may be conceived as divided. This is not necessarily true, but it is approximately true for the forms usually employed by engineers. When the stress is not axial it cannot be considered, even approximately, as uniformly distributed; the greatest intensity of stress will occur towards that edge of the cross section which is nearest

to the point where the resultant meets the plane of the cross section. The following considerations allow the maximum intensity of stress to be approximately calculated in most of the cases which are practically met with. 1. Let the cross section (fig. 6) have an axis of symmetry XX_1, and let YY_1 be an axis passing through the centre of gravity of the surface at right angles to XX_1; the axis YY_1 will be called the *neutral axis*. 2. Let the resultant stress pass through some point A in the axis XX_1, at a distance x_0 from the axis YY_1. 3. Let the material be such that its modulus of elasticity is constant under all the intensities of stress which result from the given total stress; then calling the whole force P, the area of the cross section S, the mean intensity of stress p_0, the maximum intensity of stress p_1, the maximum distance of any point of the cross section from the axis x_1, and representing by I the moment of inertia (*vide* § 9) of the surface of the cross section round the axis YY_1, we observe—first, that

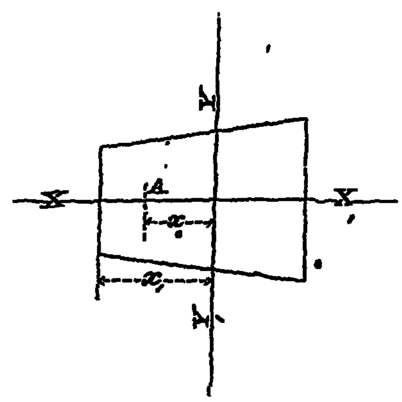

Fig. 6.

$$p_0 = \frac{P}{S};$$

and secondly, that the non-axial force may be assumed to produce a uniformly varying stress, the maximum intensity of which will occur at the distance x_1 from the neutral axis on the same side as x_0 is taken. This uniformly varying stress is equivalent to a uniformly distributed stress of the intensity p_0 and a couple of the moment aI, where a is the constant rate of increase of the stress. We also know by the principles of mechanics that the force P applied at a distance x_0 from the centre might be replaced by an equal force P at the centre and a couple of the moment Px_0. Hence we have—

$$1. \quad . \quad . \quad . \quad . \quad Px_0 = aI, \text{ or } a = \frac{Px_0}{I}.$$

But the maximum intensity of stress due to the couple will be $x_1 a$, *i.e.*, $\frac{Px_0 x_1}{I}$, and the maximum stress p_1 may be considered as consisting of two parts,—first, the mean intensity of stress p_0, and secondly, the maximum stress due to the couple. Hence we have—

$$2. \quad . \quad . \quad . \quad p_1 = p_0 + \frac{Px_0 x_1}{I} = p_0\left(1 + \frac{x_0 x_1 S}{I}\right).$$

This equation shows that the maximum intensity of stress increases very rapidly as x_0 increases, and it must be borne in mind that the ultimate strength of any member of a structure is determined, not by the mean stress, but by the maximum stress on any part, for when the part most strained yields the structure is weakened thereby, and this failure must continue to extend until the whole yields.

§ 9. *Note on the Value of* I, *the Moment of Inertia of the Cross Section.*—Suppose the cross section divided into a very large number of rectangles, so small that the distance x of the centre of each from the neutral axis may be taken as sensibly expressing the distance of every part of the rectangle; then I is the sum of the products of the areas of all the elementary rectangles each multiplied into the square of its distance from the neutral axis; or calling the area of the elementary rectangle $\Delta x \Delta y$,—

The subjoined table gives the values of I for some simple geometrical forms; the axis in all cases passes through the centre of gravity of the surface.

TABLE V.—*Moment of Inertia* = I.

Surface	Neutral Axis.	I.
Circle, radius r	Diameter	$\frac{1}{4}\pi r^4$
Square, side d	Parallel to one side	$\frac{1}{12}d^4$
Square, side d	Diagonal	$\frac{1}{12}d^4$
Rectangle with sides d and b	Parallel to b	$\frac{1}{12}bd^3$
Triangle, base b, height d	Parallel to b	$\frac{1}{36}bd^3$

Whenever a cross section can be conceived as obtained by the addition or subtraction of one surface to or from another, both surfaces having a common neutral axis, the value of I for that cross section is got by adding or subtracting the value of I for one surface to or from that for the other; thus for a ring surface, with external and internal radii r and r_1, the value of I is—

$$\tfrac{1}{4}\pi(r^4 - r_1^4).$$

The value I_1 of the moment of inertia of any plane surface S round an axis in its own plane parallel to the neutral axis, and at a distance x_0 from that axis, is given by the equation—

$$2. \quad . \quad . \quad . \quad . \quad . \quad I_1 = I + Sx_0^2,$$

where I is the moment of inertia of the surface round a neutral axis, *i.e.*, round a parallel axis passing through the centre of gravity of the section. We can thus obtain the value of the moment of inertia I of complicated cross sections whenever we can divide these into rectangles, circles, or triangles; for then, calling s_1, s_2, s_3, &c., the surfaces of each elementary part, x_1, x_2, x_3 the distances of the centre of each part from the neutral axis of the whole cross section, and I_1, I_2, I_3, the moments of inertia of each element calculated round its own neutral axis, we have the moment of inertia of the whole round its neutral axis—

$$3. \quad . \quad . \quad . \quad . \quad . \quad I_0 = \Sigma I + \Sigma s x^2.$$

§ 10. *Specific Gravity of Materials.*—In order to calculate the load due to the superstructure of a bridge, and the stability due to the weight of the abutments and anchorages of arches and suspension bridges, it is necessary to know the specific gravity of the materials employed—specific gravity being for the purposes of the present article defined as the weight of the material in lbs. per cubic foot. The following are the most useful numbers:—

TABLE VI.—*Weight per Cubic Foot of Different Materials*

Name of Material.	Weight of cubic foot in lbs.
Water (pure) at 39°·4. Fahr.	62·425
Basalt	187·3
Brick	100 to 135
Brickwork (ordinary)	112
Chalk	117 to 174
Clay	120
Granite	164 to 172
Limestone and Marble	169 to 175
Masonry	116 to 144
Mortar	86 to 119
Mud	102
Sandstone	130 to 157
Sand (damp)	118
Sand (dry)	88·6
Asphalt	156
Concrete (ordinary)	119
Concrete in cement	137
Earth	77 to 125
Slate	175 to 181
Trap	170
Cast-iron (average)	444
Wrought Iron (average)	480
Red Pine	30 to 44
Larch	31 to 35
Oak (European)	43 to 62

imperfect manner. To make the frame into a true beam, this tendency of the loaded frame to slip through between the others must be counteracted by *tongues*, T, T_1, T_2, projecting from one frame and working in a groove in the neighbouring frame (*vide* § 19). Each tongue should be made so that it does not abut against the bottom of the groove, and is thus incapable of resisting any horizontal force—it must neither prevent the whole beam nor any part of it from being extended or compressed longitudinally.

The structure will now be found capable of carrying weights as a beam. It deflects or bends as in fig. 11

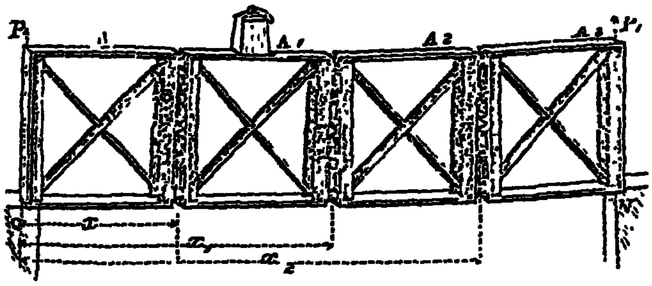

Fig. 11.

under the action of a load on A_1; all the pieces of india-rubber above the centre of the beam are then compressed; all those below the centre are then extended; and at the sections between the frames the horizontal internal forces are wholly met by the elastic reaction due to these horizontal extensions and compressions.

At any one section, say at a distance x_1 from the support Q, the pieces c_1 and d_1 are just as much compressed as the pieces $b_1 a_1$ are extended; the equal and opposite parallel resultants of these forces consequently constitute a couple, and the moment of this couple must be equal to the moment of the couple tending to bend the beam at this section, or to what is called the *bending moment*; now the *bending moment* in this simple case is due to the upward vertical reaction P_1 at N and the equal downward force with which the frame A_1 bears on the tongue T_1; for it is clear that, neglecting the weight of the frame, if a weight W on frame A_1 is borne by two forces P and P_1 at the two piers, the tongue next N must also bear a vertical force P_1 and the tongue next Q a vertical force P. The stresses borne by the india-rubber pieces are exactly the same as if the frame A_1 were firmly held, and a vertical force P_1 applied to pull up the right hand part of the beam, while the tongue T_1 acted as a hinge; the moment tending to turn the right hand part round in a left-handed direction would be $P_1 (L - x_1)$. This moment is resisted by the elasticity of the india-rubber, which must exert an equal and opposite moment round the same point. Calling s_1, s_2, s_3 the sectional areas of the pieces of rubber, and y_1, y_2, y_3 their distances from the axis where the section is neither extended nor compressed, and p_1, p_2, p_3 the intensity with which each piece is strained, the moment due to the elasticity of the pieces of rubber tending to turn back the left hand part of the beam in a right-handed direction will be Σpsy. Now, if the modulus of elasticity of the rubber is constant, the stresses p_1, p_2, p_3 will be proportional to their distance from the unstrained axis; thus if b_1 is 18 inches from the axis and c_1 only 9 inches, b_1 being shortened twice as much as c_1, the stress on b_1 will be twice that on c_1, and calling a the stress at unit distance from the axis we have $p_1 = ay_1$ and $p_2 = ay_2, p_n = ay_n$, so that we may write $\Sigma psy = a\Sigma sy^2$ as the expression for the moment of the elastic forces. Hence equating the bending moment and the moment of the elastic forces, we have—

1. . . . . $P_1(L - x) = a\Sigma sy^2$.

From this equation when the load is given we may determine a, and hence the intensity of the stress $p = ay$ at any distance y from the axis. If this intensity is less than the safe stress for the material, the beam is, at the section considered, strong enough to bear the load so far as the horizontal extending and compressing forces are concerned.

Thus if the dimensions of the beam be those given above and it be supported so that L may be 6 feet and the distance x_1 2 feet 3 inches, the distance y of the outermost piece of rubber from the unstrained axis 8 inches, the weight 50 ℔, and the section of the rubber in each row 2 inches (two cylinders side by side, each with a section of 1 inch) we shall have as the numerical values in the above equation, neglecting the weight of the frame itself (P_1 being nearly = 18·7), 18·7 × 45 in. $= a\,(4 \times 8^2 + 4 \times 4^2)$ from which $a = 2{\cdot}64$; then the force supported by each inch of either of the rows of rubber a_1 or d_1 will be $p = 8 \times 2{\cdot}64 = 21{\cdot}12$ ℔; the stress on each of the inner rows will be half this amount; the same equations give the load which (so far as that particular section is concerned) can safely be placed on the frame A_1 consistently with a given stress per square inch on the rubber. The strength required in the tongue T_1 is still more easily found, the stress tending to shear it off is P_1, and it must have a sufficient cross section to bear that shearing stress. Similar reasoning would allow us to calculate the strength of our beam at either of the two other sections where the india-rubber pieces and tongues are placed. The general relation between the external and internal forces in any beam is similar to that illustrated by the model; at any section the moment due to the elastic forces must balance the moment due to the external forces tending to bend the beam at that section. The problem, therefore, of determining the strength of a beam at any section resolves itself, so far as the horizontal forces are concerned, into finding expressions for these two moments and equating them. The equation thus stated will give the maximum horizontal stress thrown on the material of a given girder by a given load, or it will give the maximum load on a given girder consistent with a safe stress on the material, or if, as is generally the case in bridges, the load and maximum safe stress on the material are given, the equation will allow us to fix the dimensions required for the cross section of the beam so far as the *horizontal forces are concerned*. The provision to be made for resisting the shearing stress for which the tongues are required in the model will be explained in § 19.

In any solid beam the stresses do not divide themselves into horizontal and vertical components. This division is made by the engineer to simplify his calculations. In the beam the actual stress at any point will be the resultant of the horizontal stress (borne by the india-rubber in the model) and the vertical stress (borne by the tongue in the model). The diagram, fig. 12, shows the direction of the resultant stress at each point of a beam of rectangular cross section. The curves are called the lines of principal stress.

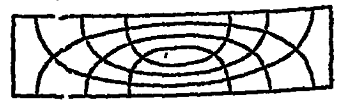

Fig. 12.

§ 14. *Bending Moment and Moment of Elastic Forces or Moment of Stress.*—The bending moment for a given section of a given beam under a given distribution and magnitude of load is the sum of the moments, taken relatively to the section, of all the external forces acting on one of the two segments into which the section divides the beam. It is a matter of indifference which segment is considered, but the moment on one segment will be positive and that on the other negative. Let x be the distance of the section from the left hand abutment Q of any beam of span L (fig. 13). Let P be the load borne by abutment Q, and P_1 the load borne by

abutment N. Let the load on the beam, including the weight of the beam, be divided into any number of equal or unequal parts. Let those loads which lie to the left of the

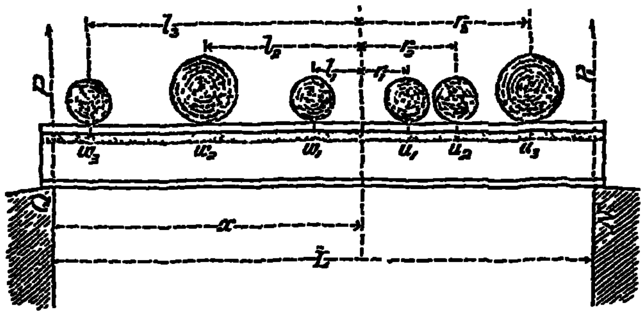

Fig. 13.

section be called w_1, w_2, w_3, &c., and let the distances of their centres of gravity from the section be called l_1, l_2, l_3. Let those loads which are to the right of the section be called u_1 u_2, u_3, and let their distances from the section be called r_1, r_2, r_3 &c. Let the bending moment at the section be called M, then by the above definition

1 . $M = Px - \Sigma wl = \Sigma ur - P_1(L-x)$.

This bending moment is resisted at the section by the elastic forces in the beam called into play by compression at the top and extension at the bottom, or, in other words, called into action by the stresses on the material. Limiting our consideration to those cross sections which have a vertical axis of symmetry, and to those materials which have a constant modulus of elasticity for tension and compression, it is easy to find a general expression for the moment of the elastic forces, which will hereafter be designated by the letter μ. Let the horizontal axis ZZ_1 (fig. 14) be a line along which the material is unstrained,—

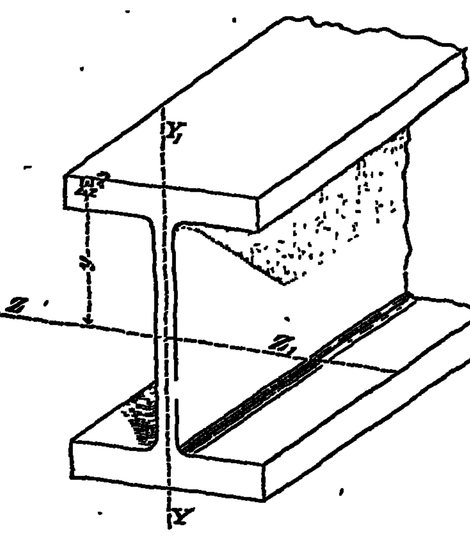

Fig. 14.

all the portions above this line being compressed, and all the portions below this line being extended. Conceive the section divided into little elementary surfaces, the area of each being equal to the product of the little elementary length Δy into the little elementary length Δz, the force exerted by the elasticity of this element will be proportional to its area $\Delta y \Delta z$ and to its distance y from the axis ZZ_1, for the longitudinal extension or compression is directly proportional to this distance; then calling a, as before, the rate at which the stress increases with the increase of y, or in other words the intensity of the stress at the unit distance from ZZ_1, we shall have for the force exerted by each element the expression $ay\Delta y\Delta z$. Now, as the section is not moved as a whole along the beam in either direction, we must have $\Sigma ay\Delta y\Delta x = 0$, that is to say, the sum of the positive must be equal to the sum of the negative forces. Let the constant quantity $a\Delta y\Delta x$ be conceived as the weight w of a thin plate of the area $\Delta y\Delta x$, the moment of this weight relatively to the axis will be wy, but as we have the sum of the moments $\Sigma wy = \Sigma ay\Delta y\Delta x = 0$, the axis ZZ_1 round which these moments are taken must pass through the centre of gravity of the section. This axis is called the *neutral axis* of the beam (*vide* § 18). The expression for the force exerted by each element being $ay\Delta y\Delta x$, the moment of this force, or, in other words, for the moment due to the stress, is given by the expression $ay^2\Delta y\Delta z$; then for the moment μ of all the forces round ZZ_1 we have—

2. . . . . $\mu = a\Sigma y^2\Delta y\Delta z = aI$,

where I is the moment of inertia of the surface of the cross section. This expression μ is Rankine's moment of resistance to flexure; it may also be called the moment of the elastic forces, or, as suggested by Professor Kennedy, the moment of stress.

The greatest intensity of stress p_1 occurs at the greatest distance from ZZ_1, or at the distance $\frac{1}{2}d$ if the depth of the beam be called d, and the axis ZZ_1 be equidistant from top and bottom. In this case we have—

$$p_1 = \frac{ad}{2}, \text{ or } a = \frac{2p_1}{d};$$

hence we may write for sections with two axes of symmetry, and for materials having equal strengths and constant moduli of elasticity under tension and compression—

3. . . . . $\mu = 2\,\dfrac{p_1 I}{d}$.

Now, the general condition of equilibrium between the external forces and the elastic forces at the section is simply $M = \mu$, hence when the beam does not break we have also—

4. . . . . $M = \dfrac{2p_1 I}{d}$.

Whenever the amount and distribution of load on a given girder is known the bending moment M is to be calculated from equation 1, and then equation 4 allows us to calculate p_1; or if we know the value of f, the ultimate strength of the material to resist tension and compression, this equation enables us to find what moment M_1 is required to break the beam at that section, and therefore what load distributed in a given way the beam can bear; thus we have—

5. . . . . $M_1 = \dfrac{2fI}{d}$.

In a beam of uniform strength the value of $\dfrac{2fI}{d}$ will at every section be equal to the value of M_1, the moment due to external forces at that section.

When the material is not equally strong to resist tension and compression, let f_t and f_c be the two strengths (per unit of cross section), but let the modulus of elasticity be assumed constant as before. Then, as above, the unstrained axis will be the axis passing through the centre of gravity of the section, and the intensity of stress at any distance y above or below that axis will be ay; let y_c be the distance of the uppermost element of the cross section from the horizontal axis, and let y_t be the distance of the lowermost element. Then the greatest stress will occur at the top if y_c be greater than y_t, but at the bottom if y_t be greater than y_c; since, however, the material is not equally strong to resist tension and compression, it does not follow that it will give way where the stress is greatest, and the beams will yield first at that edge where the ratio $\frac{y}{f}$ is greatest.

We must, therefore, on a beam of this kind ascertain whether $\frac{y_c}{f_c}$ or $\frac{y_t}{f_t}$ is the greater, and replace $\frac{d}{2}$ in equations 3 and 4 by the value of y in the larger of the two expressions. Having selected y and f in this manner, we have—

$$6. \quad \ldots\ldots \quad M_1 = \frac{fI}{y}.$$

§ 15. *Modulus of Rupture.*—If the above hypothesis of a constant modulus of elasticity in a given material under both descriptions of stress, and under stresses of all magnitudes, were accurate, we should require no fresh experiments to determine the values of f_c and f_t; these would be already known from direct experiments on tension or compression. For both wrought and cast iron beams of the maximum strength, such as will be described hereafter, experiment gives results closely in accordance with strengths calculated by equation 6; and for wrought iron beams the hypothesis appears to be approximately true when tested by experiment with any form of beam. But it is usual, in calculating the strengths of beams or bars of simple rectangular or circular cross section, to assume that y is equal to $\frac{1}{2}d$ and to employ equation 5 instead of equation 6. The imperfection of the theory is then to some extent corrected by determining f from direct experiments on solid rectangular bars. The value of M_1, I, and d being known, f is calculated from equation 5, and the number thus determined has received the name of modulus of rupture.

TABLE VIII.—*Modulus of Rupture = f (Rankine).*

Name of Material.	Lbs. per sq. inch.
Wrought Iron Plate Beams	42,000
Cast-iron Solid Bars	33,000 to 43,000
Fagersta Steel (Kirkaldy)	110,000 to 191,000
Red Pine	7100 to 9540
Larch	5000 to 10,000
Oak (British and Russian)	10,000 to 13,600
Indian Teak	14,770
Sandstone	1100 to 2360

Experiments on the modulus of rupture have generally been made by hanging weights at the centre of a rectangular bar, supported at both ends, and increasing the weights till the bar breaks. Then let b and d and l be the breadth, depth, and length of the bar in inches, and W the breaking weight. M is a maximum at the centre, and, neglecting the weight of the bar, is equal to $\frac{1}{4}Wl$; substituting the value of I for a rectangle in equation 3, we get

$$\mu = \tfrac{1}{6}fbd^2,$$

and equating M and μ we have—

$$1. \quad \ldots\ldots \quad f = \frac{3Wl}{2bd^2},$$

or, if the span is measured in feet and called L_1, while b and d are measured in inches, we have—

$$2. \quad \ldots\ldots \quad f = 18\,\frac{WL_1}{bd^2}.$$

Hence the modulus of rupture is stated by Rankine to be "eighteen times the load required to break a bar of 1 inch square, supported at two points 1 foot apart, and loaded in the middle between the points of support."

The use of a modulus of rupture determined by experiment on a special form of beam is not based on any satisfactory principle. The employment of this modulus is an imperfect means of correcting a defective theory. A different value is found for f when bars of different sizes or cross sections are tested. Even the same bar broken in different ways will give a sensibly different value for f. The use of this modulus is, however, convenient when great accuracy is not required.

§ 16. *Expressions for the Bending Moment caused by Special Distributions of Load.*—From equation 1, § 14 it is easy to deduce the following values for the bending moments in beams subject to various simple distributions of load:—

Case 1. Let a single load W be placed at the centre of a beam; let M_x be the moment at any section taken at the distance x from the nearest pier; let M_c be the moment at the centre of the span, we have—

$$1. \quad \ldots\ldots \quad M_x = \tfrac{1}{2}Wx,$$

$$2. \quad \ldots\ldots \quad M_c = \tfrac{1}{4}Wl.$$

M_c is the maximum moment at any section of the beam.

Case 2. Let a single load W be placed at the distance x_1 from the nearest pier; let M_{x_1} be the moment at the section where the load is applied—

$$3. \quad \ldots\ldots \quad M_{x_1} = W\frac{lx_1 - x_1^2}{l}.$$

M_{x_1} is the greatest moment which the load at that place produces at any part of the beam, and increases as the load rolls from the end to the centre in proportion to the product $(l - x_1)\,x_1$ of the parts into which the load divides the beam.

Case 3. Let the load be uniformly distributed along the beam so that each unit of length bears an equal load $w = \frac{W}{l}$; when the unit of length adopted is the foot, the quantity w is called the *load per foot run.* Let M_c and M_x be as before the moments at the centre of span, and at any distance x from the nearest pier, we have—

$$4. \quad \ldots\ldots \quad M_c = \tfrac{1}{8}wl^2,$$

$$5. \quad \ldots\ldots \quad M_x = \tfrac{1}{2}w\,x(l - x).$$

When a uniform passing load, such as is approximately represented by a train of locomotives, of length at least equal to the span of the bridge, comes on to a bridge at one end and passes over to the other, gradually covering the whole span, the bending moment reaches a maximum for all sections when the bridge is wholly covered. The bending moment at any section for a combination of loads is the sum of the moments at that section due to each load taken separately. When many different distributions of load have to be provided for engineers are in the habit of representing the bending moment for each load by a line, the ordinates of which are the bending moments at the sections, and the abscissæ the distances of the several sections from one point of support. The lines having been drawn for the several loads, it is easy by superposition to find the bending moment due to the combination, and thus to pick out for each section of the girder the maximum bending moment which any combination gives. Figs. 15, 15*a*, 15*b*, and 15*c* show diagrams giving the curve of bending moments for some simple distributions.

Fig. 15 shows the line of bending moments when a single

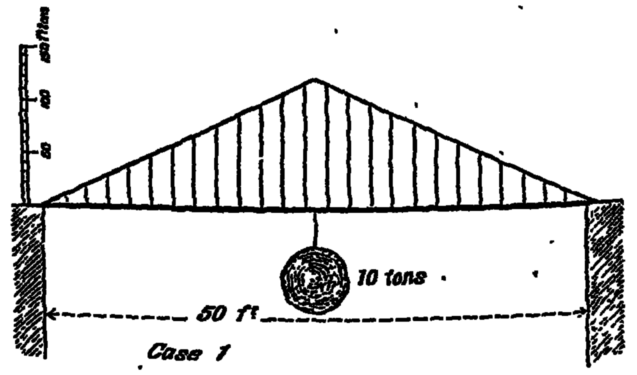

Fig. 15.

load of 10 tons hangs at the centre of a span of 50 feet. The vertical ordinates measured on the vertical scale give the bending moments at each section. Fig. 15*a* shows the curve of bending moments for a uniformly distributed load

of 1 ton per foot run on a span of 50 feet. The upper curve in fig. 15b shows the curve of bending moments

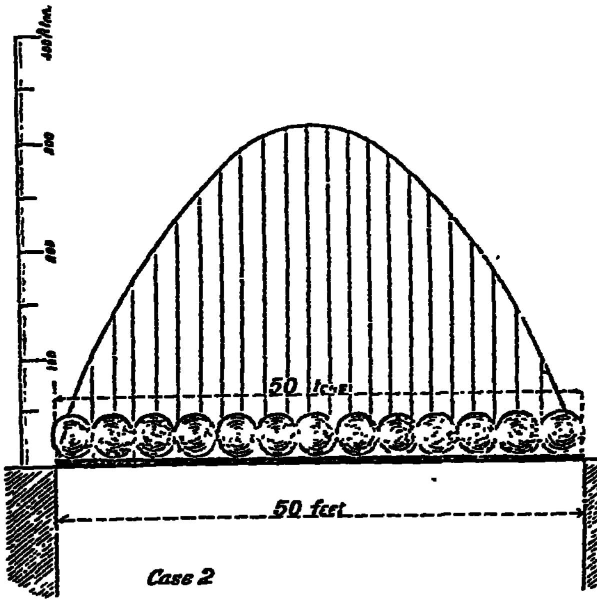

Fig. 15a.

when the loads of case 1 and 2 both occur at once. This curve is obtained by adding the ordinates in case 1 to those in case 2. Fig. 15c shows the four separate lines of

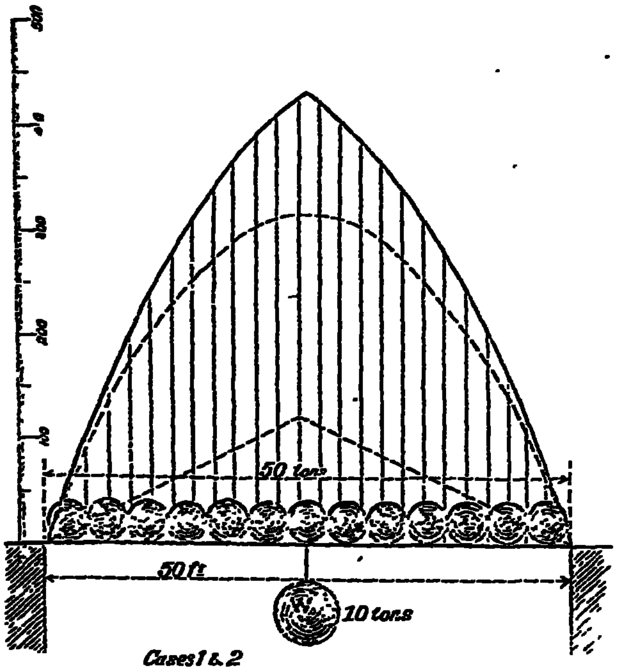

Fig. 15b.

bending moment for four separate weights, and the broken upper line is the line of bending moments for the case when the four loads all rest at once on the beam; it is got by simply adding at each point of the span the four ordinates due to the four loads considered separately. The curve in fig. 15a and the curve ABCD in fig. 15c are parabolas.

The bending moment at any section is reckoned as *positive* when the external forces on the beam tend to turn the right hand side of the beam in a left-handed direction (or in the direction opposite to that followed by the hands of a watch), in other words, when the bending moment tends to bend the beam downwards between the supports. We shall hereafter see that in beams with more than two supports the bending moment is at places *negative*, tending to bend the beam up; the curve of bending moments is drawn below the datum line where the moments are negative. Fig. 25a gives an example of a curve of bending moments of this class.

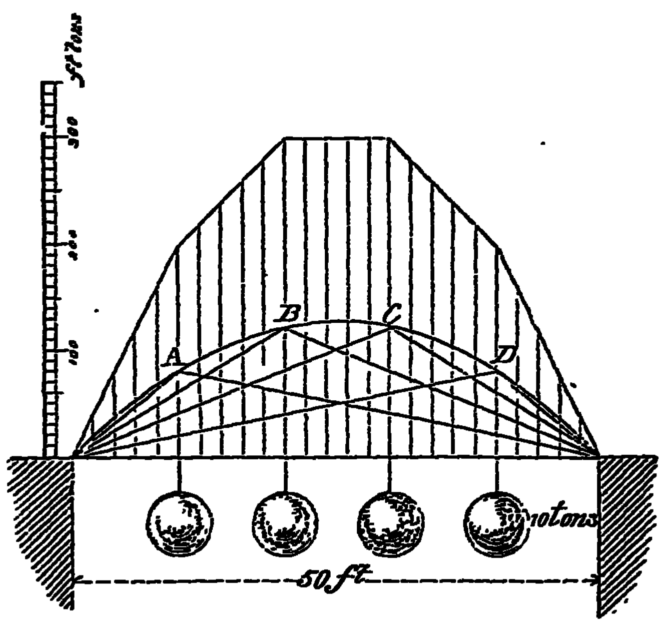

Fig. 15c.

§ 17. *Moment of Elastic Forces.*—On the hypothesis above stated, viz., that for any one material the modulus of elasticity may be taken as constant for all stresses, and assuming that our investigation is to be confined to those cases in which the cross section of the beam has a vertical axis of symmetry, and in which the centre of gravity lies at a point equidistant from the top and bottom of the beam, the general equation—

$$\mu = a\mathrm{I} = 2\frac{p_1\mathrm{I}}{d},$$

(3, § 14), allows simple expressions of the value of μ to by obtained for all practical cases by substituting for the ratio $\frac{2\mathrm{I}}{d}$ its value in terms of the dimensions of the cross section. Thus, for a rectangle of the depth d and breadth b,

$$\frac{2\mathrm{I}}{d} = 2\frac{bd^3}{12d} = \frac{bd^2}{6} = \frac{\mathrm{S}d}{6},$$

where S is the area of the cross section. The following are the values for the commonest forms of cross sections.

TABLE IX.—*Values of* $\frac{2\mathrm{I}}{d}$ *for various Cross Sections.*

Form of Cross Section.	$\frac{2\mathrm{I}}{d}$ In Terms of Linear Dimensions of the Cross Section.	$\frac{2\mathrm{I}}{d}$ In Terms of the Area of the Cross Section (S) and the Depth.
Square, side b	$\frac{b^3}{6}$	$\frac{\mathrm{S}b}{6}$
Rectangle, breadth b depth d	$\frac{bd^2}{6}$	$\frac{\mathrm{S}d}{6}$
Circle, radius r	$\frac{\pi r^3}{4}$	$\frac{\mathrm{S}d}{8}$
Hollow circle, external radius r, internal r_1	$\frac{\pi(r^4 - r_1^4)}{4r}$	$\frac{\mathrm{S}d}{4}$ when r_1 differs little from r.
Hollow rectangle, internal depth d_1, breadth b_1	$\frac{bd^3 - b_1d_1^3}{6d}$	$\frac{\mathrm{S}d}{2}$ when moment of web is neglected, and S is taken as area of cross section of flanges only, and d_1 differs little from d.

Substituting the modulus of rupture f (Table VIII.), for p_1 in equation 3, § 14, we can from the above values of $\frac{2I}{d}$ calculate the ultimate strength of any given cross section to resist any given bending moment. Thus, if we wish to know what breadth we must give a bar of wrought iron 3 inches deep, supported at points 3 feet apart, so that it may break with 2000 lb at the centre, we find the maximum bending moment from equation 2, § 16; and we find the value of μ from equation 3, § 14, by the help of table IX. Then equating M and μ, we have—

1. . . . . . $\frac{1}{4}WL = \frac{1}{6}fbd^2$,

from which $b = \frac{6WL}{4d^2f} = \frac{6 \times 2000 \times 36}{4 \times 9 \times 42000} = \cdot 286$.

Since the strength of the beam is directly proportional to the values of $\frac{2I}{d}$, table IX. shows us how to dispose of the material in the cross section so as to obtain the maximum strength. The expression for a rectangle shows that the strength is proportional to the breadth of a beam, but to the square of its depth; and therefore, as appears in the second column, for the same quantity of material the strength of a rectangular beam increases simply as the depth, so that a deep narrow beam is preferable to a square or to a broad and flat one. The circular cross section is weak compared even with the square (the ratio for the same quantity of material is ·846 to 1). The hollow tube is stronger than the thin rectangular plate of the same depth and *cross section*, but clearly the material is much best applied when wholly used in the form of two thin flat plates, separated from one another by a web of the maximum depth d which can be practically allowed. Thus the hollow rectangle is the form preferred for large girders, the material intended to resist the bending moment being placed in the top and bottom members of the girder, and kept apart by vertical webs, which add somewhat to the moment μ, but which are chiefly employed to resist shearing stress, as will be presently shown.

The I section, fig. 16, is that employed for small girders; the moment of its elastic forces is exactly the same as that of a hollow rectangle, having the same values for b, d, and d_1, and having a value for b_1 equal to $2b_2$ in fig. 16 It is usual to neglect the strength to resist bending moment given by the vertical web, and to design the girder so that the top and bottom plates are alone sufficient to meet this stress.

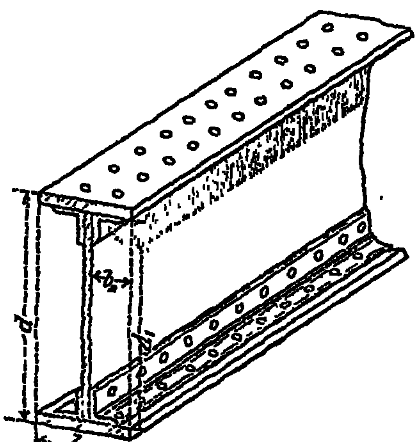

Fig. 16.

The model, fig. 10, shows at once that to obtain the full resistance from the material employed to resist tension or compression consistently with a given depth, it must all be placed in two horizontal plates at the extreme top and bottom of the beam; moreover, if $\frac{1}{2}$S is the sectional area of the top or bottom member, and f is the stress it will bear (assumed equal for tension and compression), the maximum moment which the elastic forces can exert is the sum of the moments due to the top and bottom members about the axis or tongue, *i.e.*, $2(\frac{1}{2}f\mathrm{S} \times \frac{1}{2}d)$ or $\frac{1}{2}f\mathrm{S}d$; or dismissing the idea of an axis through the centre of gravity of the section, we may (to refer again to the illustrative model) take the moment of the elastic forces round the line running through the top row of india-rubber pieces looked upon as a fulcrum, and then the moment of the bottom row will be as before $\frac{1}{2}f_t\mathrm{S}d$, and will be the *whole moment* of the elastic forces. Similarly, by taking the bottom row as the fulcrum, we see that the moment due to the top row will be the same. This moment calculated in either way is the *whole* moment of the elastic forces. This latter mode of considering the moment in the simple case of an I or hollow rectangle, enables us to find the value of the moment of elastic forces for those cases in which the ultimate strength may not be the same for tension and compression. Thus, assume that the strength of wrought iron to resist tension, or f_t, is 25 tons, and its strength to resist compression, or f_c, is 20 tons, then calling S_t the area of the bottom member at the section considered, and S_c the area of the top member, we have for μ the two values 25 S_td and 20 S_cd; whichever happens to be the smaller will represent the available value of the moment of the elastic forces. Consequently we must, in order not to waste material, design the beam so that the ratio of the material in the upper member to that in the lower member shall be 5 to 4. That this ratio ought to be adopted is evident from the fact that the strength of the beam will be limited by that of the weaker member. No structure is perfectly designed unless it will when overstrained give way simultaneously in every part. The foregoing theory, the soundness of which is borne out by experiment, tacitly assumes that, although the strength differs, the modulus of elasticity is constant for tension and compression. For example, if the flanges are made with sections bearing to one another the proportion of 4 to 5, the neutral axis (neglecting the web) will, assuming E constant, be at a distance from the top or larger flange equal to $\frac{4}{9}$ths of the depth; then the intensity of stress varying directly as the distance from the neutral axis will for the two flanges be in the desired ratio of 4 to 5. Thus we see not only that the I, or hollow rectangle, has the advantage of being the best form for a girder, but that it allows us easily to arrange the material to the best advantage, even when its strengths to resist tension and compression are dissimilar. Values of the modulus of rupture given above are therefore not to be applied to this design of beam, but the values of f_t and f_c are to be taken from Tables I. and II. In the case of cast-iron the member under tension is made with six times the cross section of the member under compression, the reason being the same as that for making the ratio of the upper and lower members of the wrought iron beam 5 to 4. When a cast-iron beam is thus designed, the moment which any section can exert will for a given depth be proportional to the area S_t of the lower flange. Professor Hodgkinson verified this theory experimentally, and found that the ultimate value of the moment due to elastic forces expressed in lbs and inches for beams thus designed was $\mu = 16500\ \mathrm{S}_td$. The value of the constant agrees closely with the tensile strength of cast-iron. The experiments by Professor Hodgkinson are therefore consistent with the assumption, that although the strength of cast-iron is very different in resisting tension and compression, nevertheless the modulus of

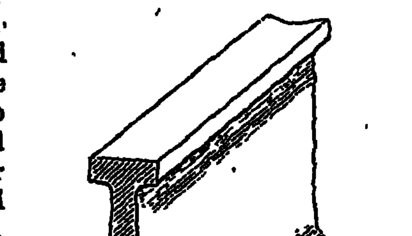

Fig. 17.

elasticity is equal under the two kinds of stress. Fig. 17 shows the cross section usually adopted for cast-iron girders.

§ 18. *Neutral Axis.*—The line ZZ_1, fig. 14, perpendicular to the plane in which a beam is bent, and passing through the centre of gravity of any given cross section, is called the *neutral axis* of the beam at that point. The surface containing all the neutral axes is the *neutral surface.* Practical engineers sometimes apply the term neutral axis to the longitudinal line showing the neutral surface on a side elevation, but in this article, as in Rankine's works, the words will be used as defined above.

When the assumption is made that the modulus of elasticity is the same for any given material whether under tension or compression, notwithstanding any difference in the ultimate strength to resist tension or compression, then it follows, as has been shown, that the neutral surface of a bent beam will separate it into two parts, one of which is compressed while the other is extended. The neutral axis in any cross section then contains the only part of the material which is neither extended nor compressed.

If, however, the average value of E for stresses varying between zero and the maximum intensity of compression to which the beam is subjected be different from the average value between zero and the maximum intensity of tension, then the neutral axis as above defined will not be the *unstrained* axis; the neutral axis is determined as soon as the cross section of the beam is known, being independent of the material used; the unstrained axis may differ in beams of the same cross section but made of different materials; for if the average of E be greater say for compression than for tension, this will raise the unstrained axis above the neutral axis. It is not improbable that the position of the unstrained axis may vary in the same beam with loads similarly distributed, but of different magnitude, and also with different distributions of load. Until experiments shall have accurately determined the relation of E to the intensity of stress we have no means of determining accurately the position of the unstrained axis. Even when E is constant the neutral axis, as above defined, will not always in practice correspond with the unstrained axis; for instance, in a beam which was not only bent across, but also compressed endways, the unstrained surface would no longer contain the neutral axis as above defined. The unstrained surface might be near one edge of the beam, or, indeed, if the general compression were large and the bending small, the whole beam might be under compression, so that no part was unstrained. By restricting the use of the words neutral axis to the above definition, and using the words unstrained axis, or unstrained surface, for the second idea all ambiguity will be avoided.

The actual position of the unstrained axis in any beam of any material subject to a bending moment depends on the relative values of the modulus of elasticity for the material under all stresses positive and negative, great and small; but as the simple hypothesis of a constant modulus is borne out by experiment in the most important materials, it is unnecessary to pursue this subject further.

§ 19. *Shearing Stress.*—The theory hitherto given shows the relation between longitudinal stresses (such as are resisted by the india-rubber in the model) and the load on the girder; but in designing a girder we have also to provide for the shearing stress or transverse force tending at each imaginary cross section to make the more heavily loaded of the two parts into which it divides the bridge slide down past the other. This shearing stress was resisted by the tongues of the model. The total shearing stress at any section is the sum of all the vertical forces acting on the beam on one side of the section. The shearing stress at any section will be called positive if the sum of the external forces on the right hand part of the beam tends to lift that portion up. Diagrams may be conveniently used to show shearing stresses, and, as in the case of bending moments, the shearing stress at any section due to two or more loads is simply the algebraic sum of the shearing stresses due to each load.

Example 1. Load W at centre between supports (fig. 18); weight of beam neglected. The shearing stress is

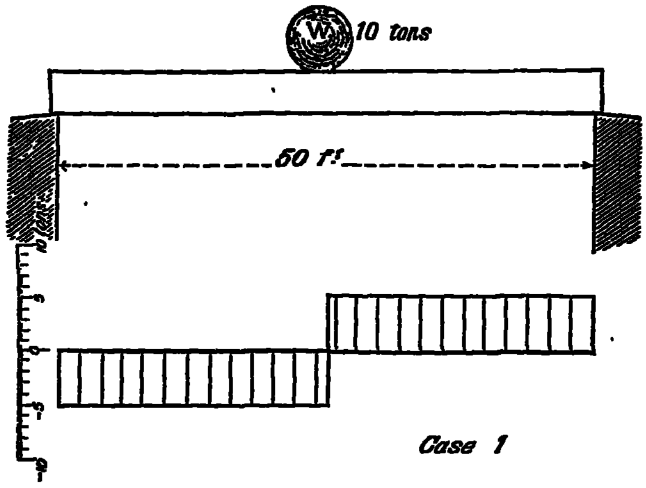

Fig. 18.

equal to $\frac{1}{2}W$ all along the beam, being the reaction at one pier; the stress is positive to the right of the load, negative to the left.

Example 2. Uniformly distributed load w per foot run (fig. 18a). The shearing stress is $\frac{1}{2}wL$ at the points of

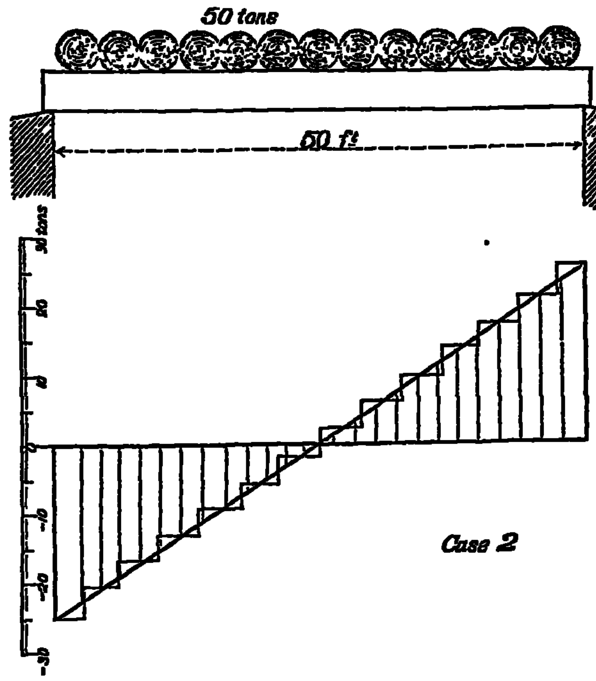

Fig. 18a.

support, and zero at the centre of the span; at any section distant c from the centre of the beam it is wc.

Example 3. A single load rolling from right to left of a beam of span L (fig. 18b). When the load is at the distance x from the right hand support the shearing stress to the right of the load is $W\frac{L-x}{L}$, and to the left it is $-\frac{Wx}{L}$. The maximum stress for each section occurs when the load reaches that section; it is positive for the right half, and negative for the left half of the beam.

Example 4. Uniform advancing load of w per unit of length

(fig. 18c). When the load covers a length x measured from the right hand pier, the shearing stress at all points beyond x towards the left is $-\frac{wx^2}{2L}$; when x is greater than $\frac{1}{2}L$

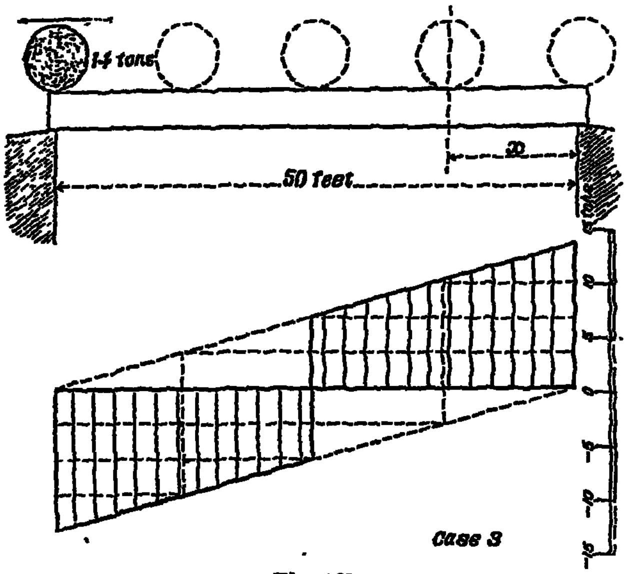

Fig. 18b

the above expression gives the maximum stress which can occur on that section with any distribution of the given uniform load. Thus the maximum shearing stress at the left end occurs when the whole bridge is loaded, and is $-\frac{1}{2}wL$; the maximum stress at the centre occurs when the bridge is half loaded, and is equal to $-\frac{1}{8}wL$. The maximum shearing stresses on the other half of the beam occur when the load comes on from the left side, and covers more than half of the beam; these stresses are equal in amount to the stresses in the left half, but are positive in sign.

The scales in figures 18, 18*a*, correspond to the shearing stresses in examples 1 and 2 for a span of 50 feet and loads of 10 tons and 1 ton per foot run respectively. The scale in fig. 18*b* corresponds to the shearing stresses in example 3 with a single passing load of 14 tons. The scale in fig. 18c, example 4, gives the maximum shearing stress which the advancing load of one ton per foot run can produce at each section. As a train leaves a bridge it produces the same shearing stresses as when it comes on to the bridge from the opposite end, the same portions being similarly loaded. The maximum shearing stress due to a passing load of this kind changes its sign at the centre of the span, as appears by diagram 18c.

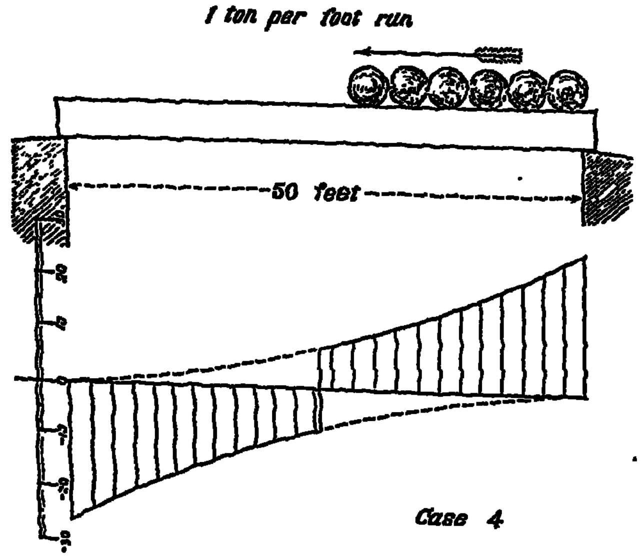

Fig. 18c.

In I girders with solid vertical webs the shearing stress is practically all borne by the web unassisted by the top or bottom members, it being clear that these would fold down at the sides under a small fraction of the total stress. Sufficient material is therefore employed in the web or upright plates to reduce the intensity of the stress to the desired amount. The shearing stress may, however, when the web is a thin iron plate, cause failure by crumpling the web, or causing it to buckle, instead of by shearing it across. This tendency is prevented by stiffening the web with angle or T irons rivetted to the sides. Mathematical analysis has not yet been very successfully applied to the determination of the amount of stiffening required; experience has given a sufficient number of examples to guide the practical designer. In cast-iron girders the web is generally much in excess of the strength required to resist shearing.

§ 20. *Factor of Safety.*—In designing a girder the load which it will have to carry is multiplied by a number called the factor of safety, varying from 3 to 6, and the girder is so designed that it shall not yield at any point with less than the load thus multiplied. If, for instance, the girder is practically to carry 1 ton per foot run, it is designed so that at no place shall it *break or yield injuriously* with less than say 5 tons per foot run. The multiplier is called the *factor of safety*. The factor of safety is required to allow for imperfections in the material as compared with picked specimens, for the wear and tear by which the strength of a structure is gradually reduced, for unforeseen loads, for jars and vibrations, for imperfection of theory, and for the sake of obtaining stiffness. This last property might be the subject of calculation, and in some cases must be separately examined. The particular factor employed depends on the judgment of the engineer. A larger factor of safety is required for a passing or moving load than for a permanent load, there being a greater uncertainty as to the stress which may be caused by vibrations or impulses due to what is sometimes called a live load. Moreover, the mere presence of a large permanent load tends by its inertia to diminish the dangerous effect of the impulses or stresses due to the passing load, so that the factor of safety should be chosen with reference to the ratio $\frac{\text{max. passing load}}{\text{max. permanent load}}$ being larger as this ratio increases. Rankine recommends that the factor of safety should for the moving load be double that employed for the permanent load. Sometimes the factor is more conveniently employed as a divisor to deduce the safe stress f_1 from the ultimate strength f of the material, rather than as a multiplier for the load. Thus the same number of square inches will be obtained in the tension member of a wrought iron girder to bear 1 ton per foot run, whether we use in the calculations 25 tons as the value of f, the ultimate strength of the material, and a load w of 5 tons per foot run, or if we use 5 tons as f_1, the safe stress on the material, and a load w of 1 ton per foot run; in short, if we call the factor of safety K, we may in equation 5, § 14, use $KM = \frac{2fI}{d}$, or making $f_1 = \frac{f}{K}$, we may write

$$1. \quad \ldots \quad M = \frac{2f_1 I}{d}.$$

The same remark applies, of course, to equation 6, § 14.

§ 21. *Weight of Girders and Roadway.*—When two girders are employed for each line of way on a railway, the weight of the iron girders per foot run will, with the usual proportions, probably lie between 0·0017L tons and 0·0025L tons, L being the span in feet. It follows from the theory given above, that for similar beams the quantity of material in the whole girder will be proportional to the square of the length, and, therefore, the quantity per foot run will be proportional to the

simple length. The constants given above are derived from practice. The weight of girders for a common road, if placed from 7 to 8 feet apart, will be nearly the same as for railway girders of the same span. The weight of a cast-iron railway girder (two girders per way) will be about 0·005L tons per foot run. The weight of the *roadway* in a railway bridge will probably be from 0·14 to 0·22 tons per girder, or double this for each line. For a turnpike road with metalling the weight will much exceed this, and should in each case be computed.

§ 22. *Design of a Girder.*—(1.) From the span and load to be carried the engineer will determine the material and form to be employed. Cast-iron may in some districts be the cheapest material for girders under 30 feet span. Wrought iron I girders are very generally employed for spans of from 30 feet to 100 feet; beyond that span lattice or framed girders are more usually employed. For extreme spans exceeding, say, 300 feet, a hollow rectangle or tubular bridge may be used, carrying the road on its top or inside the tube. The depth of the cross section is limited by the consideration that the web must be sufficiently stiff not to buckle; but for this consideration the deeper a girder could be made the better. In practice the depth is made from $\frac{1}{8}$th to $\frac{1}{15}$th of the span. The engineer will also determine whether he will keep the depth of the girder constant throughout or diminish the depth at the ends. It is impossible to graduate the material so as to give absolutely uniform strength at all sections, but by diminishing the depth towards the ends, some material may be saved without attenuating the top and bottom members to such an extent as to be inconvenient. When the general character of the design has thus been settled, the engineer will compute the probable weight of the girders and roadway or total permanent load; he will next determine the passing load for which he intends to provide.

(2.) The value of M, the bending moment, must next be computed for a sufficient number of cross sections of the beam, and for various distributions of load. For a small cast-iron girder of uniform cross section a single value of M will be sufficient, computed for the section at the centre when the girder is wholly covered with the greatest uniform load and also supports the greatest single load at the centre of the span. When, as in larger girders, the design is intended to give a structure of approximately equal strength throughout, the maximum value of M should be found for eight or ten sections; this maximum value will be that obtained when the bridge is wholly loaded with its maximum uniform load and has the maximum single load resting just over the section in question.

(3.) The maximum shearing stress must next be calculated for each of the above sections. The designer will bear in mind that the maximum stress occurs at the points of support, and that at the centre it is greatest when the bridge is half covered with the passing load.

(4.) The engineer can now compute the number of square inches S_c and S_t required at each section in the upper and lower members consistently with the factor of safety he chooses to employ; this he obtains from the expressions—

$$1. \quad . \ . \ . \ . \ . \ . \ . \quad S_t = \frac{M}{f_1 d},$$

$$2 \quad . \ . \ . \ . \ . \ . \quad S_c = \frac{M}{f_2 d}.$$

It is here assumed that the best and strongest form of girder is employed, but if a mere square or circular beam is to be used, the cross section will be obtained by equating the values of M and μ, using a safe modulus of rupture f_1.

(5.) The web will next be designed by giving it such a thickness as will, with the depth already fixed, supply the number of square inches required to reduce the stress per square inch to the *safe* or *proof* shearing stress, say 4 or 5 tons on wrought iron. When the web is a thin wrought iron plate it must be stiffened with ⊥ or angle irons. In a cast-iron girder the web must have at least the number of square inches required by the shearing stress, but the exigencies of the foundry generally require a design resulting in a great excess of strength in this part of the beam, except in beams which are tapered towards the ends, as in fig. 19. With these beams care must be taken that

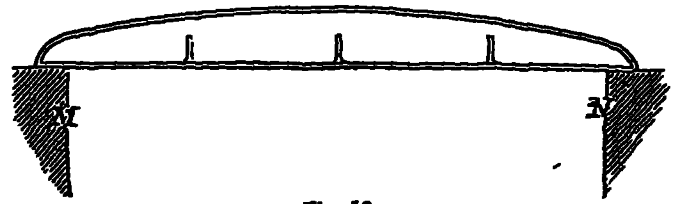

Fig. 19.

the taper is not carried to excess so as to leave insufficient metal to resist the shearing stress at M and N.

§ 23. *Practical Details.*—The designer must be practically acquainted with the forms in which his materials can be best procured. He must know the sizes in which iron or steel plates can be produced, and the forms best adapted for castings. Thus, in cast-iron beams the thickness of the web is at the bottom made equal to the thickness of the lower flange, and at the top to the thickness of the upper flange, in order to avoid permanent internal strains, which would result from unequal rates of cooling after being cast, if sudden changes of thickness in the metal were allowed. The engineer must also be familiar with the methods adopted of joining the several parts, as with the rivetting of wrought iron, the bolting together of large castings, the jointing of wood-work. He should also be acquainted with the various methods in which roadways are constructed and supported on existing bridges, and the manner in which the girders are braced one to another, so as to prevent vibration and lateral deflection due to the pressure of the wind. The examples of bridges described hereafter will give some information on these points. In long girders provision must be made by rollers, sliding plates, or suspension links for the expansion and contraction due to changes of temperature. The range in Great Britain may be taken as about 45° C. If the ends of the girder could be firmly secured at a constant distance apart this change of temperature would produce a stress of about 6 tons per square inch in wrought iron, and 3 tons per square inch in cast-iron. The result in practice would be that any attempted fastening of stone or iron work would be torn loose.

§ 24. *Deflection.*—When a bridge has been erected its deflection at the centre under a known passing load is generally observed with the object of ascertaining whether the work has been properly done, for it is assumed that any defective material or bad jointing would increase the deflection beyond that calculated on the assumption of sound material and perfect workmanship. Sometimes the practical test applied is a rough one, a certain fraction of an inch being allowed per foot of span as a safe deflection. If an inspector of bridges, having authority, chooses to limit the deflection to a constant fraction of the span, the ratio of the depth to the span must be made sufficiently great to give the desired stiffness and maintained constant for all spans; equation 5 below shows that when p_1 is kept constant and d is a given fraction of L, the deflection v will be proportional to the span. For the proof or maximum possible load, Rankine gives as the result of practice a value for the deflection of from $\frac{1}{200}$L to $\frac{1}{600}$L; but one foot deflection in a span of 200 feet would certainly be exces-

sive. A depth equal to or greater than $\frac{1}{12}$th of the span is certain to give sufficient stiffness, and the usual method is to assume the depth and then to observe whether experiment gives a deflection agreeing with that found by calculation. The calculation is made by finding the radius of curvature of the beam at a series of sections, and then determining the curve assumed by the whole beam either by integration or by an approximate graphic method. When the curve is known the deflection or versed sine is found either from the equations of the curve, or by actual measurement on the diagram to be presently described. Let R be the radius of curvature of the neutral surface of a beam at a given section, under a load producing a maximum stress p_1 at the outer elements of the section at a distance y_1 from the neutral surface. Consider a short length x of the beam fig. 20. Before deflection the length of the

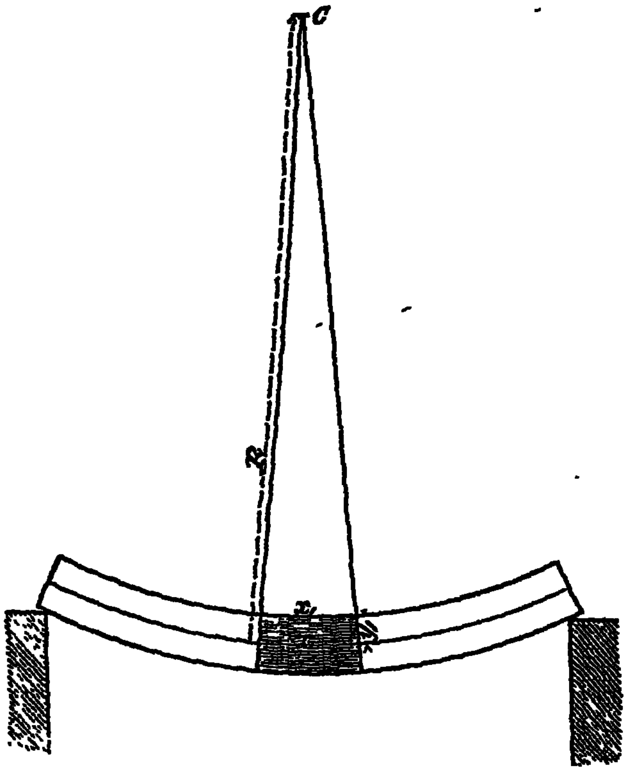

Fig. 20.

outer element is equal to x, but after deflection (if we consider the upper member) the length of the outer element will be shortened to x_1, while the length of the element in the neutral surface remains equal to x. By similar triangles we have $x : x_1 = \mathrm{R} : \mathrm{R} - y_1$, or $\mathrm{R} = \frac{y_1 x}{x - x_1}$, but $x - x_1$ is the extent to which the most compressed element is shortened, and by the definition of the modulus of elasticity we have $\mathrm{E} = p_1 \frac{x}{x - x_1}$, hence

$$1. \quad . \quad . \quad . \quad . \quad . \quad . \quad \mathrm{R} = \frac{\mathrm{E}y_1}{p_1},$$

from which the radius of curvature at any section can be obtained in terms of E, y_1, and p_1, all known quantities with a given cross section, material, and load. Another form of the same expression, which is sometimes more convenient, is obtained by remembering that $\mathrm{M}_1 = \frac{p_1 \mathrm{I}}{y_1}$, hence

$$2. \quad . \quad . \quad . \quad . \quad . \quad . \quad \mathrm{R} = \frac{\mathrm{EI}}{\mathrm{M}_1},$$

where M is the bending moment which will produce p_1. If p_1 is made equal to f_1 the maximum safe stress on the material, equation 1 or 2 gives the minimum safe radius of curvature.

We will first consider the special case in which the beam under consideration is of *equal depth and uniform strength* at all cross sections, and which we will call a beam of class 1; these conditions can only be fulfilled by any one beam for a given constant distribution of load; the beam of uniform strength for a load at the centre, for instance, will clearly not be the beam of uniform strength for a uniformly distributed load. In beams of class 1 for a given load, both y_1 and p_1 are constant, and therefore R, by equation 1, will also be constant throughout the whole length of the beam, or, in other words, the beam will bend into a circular arc. The approximate expression for the versed sine of an arc having a chord L and radius R will therefore give the deflection, and we have

$$3. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad v = \frac{\mathrm{L}^2}{8\mathrm{R}},$$

and employing for R the value given by equation 1, we have

$$4. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad v = \frac{\mathrm{L}^2 p_1}{8\mathrm{E}y_1}$$

and if $y_1 = \frac{1}{2}d$, we have

$$5. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad v = \frac{\mathrm{L}^2 p_1}{4\mathrm{E}d}.$$

If for p_1 we substitute f_1, the maximum safe stress for the given materials, equation 4 or 5 will give the maximum safe deflection, which may be called v_1; we observe, then, that the safe deflection for a beam of this class will be proportional to the square of the span, and inversely proportional to the depth of the beam.

In beams of class 1, the deflections which different loads produce will be simply proportional to the values of p_1 produced by those loads; thus, for a given distribution of load, the deflection will be simply proportional to the load; if we change the distribution of the load, keeping the total load constant, the same rule will give the solution; for instance, since a load uniformly distributed produces only half the stress p_1 which would be produced by the same load at the centre of a beam of the same span and cross section, we see that the uniformly distributed load will produce only half the deflection that would be produced by the same load at the centre of a beam of the same span and same *section at the centre* (both beams belonging to class 1). It would *not* be correct to say that a load uniformly distributed would produce half the deflection produced by the same load at the centre of the *same beam*, because the same beam cannot be uniformly strong throughout its length for two different distributions of load.

We may compare the deflections produced by the same load on various beams of similar cross section as follows:—By equation 4, § 14, we see that for a given moment M, p_1 is proportional to $\frac{d}{\mathrm{I}}$; moreover, for equal loads, the moment M at any cross section similarly placed will be proportional to L; hence we may write

$$p_1 \propto \frac{\mathrm{L}d}{\mathrm{I}} \propto \frac{\mathrm{L}}{bd^2}.$$

Substituting this expression for p_1 in equation 5, we have

$$6. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad v \propto \frac{\mathrm{L}^3}{bd^3},$$

an equation which expresses the fact that, for beams of class 1, the deflection produced by a given total load similarly applied will be proportional to the cube of the length, and inversely proportional to the breadth and to the cube of the depth. (In I girders the expression breadth must be understood as proportional to S, the section of the flange.)

Passing from beams of class 1 to beams in general, the

fundamental difference to be observed will be that the curve assumed by the neutral surface will not be that of a circular arc, so that equation 1 is no longer true. Where, however, the law according to which R varies can be stated algebraically, integration will give the value of v.

Combining equations 2 and 3 for class 1, we have $v = \frac{1}{8}\frac{M_1L^2}{EI}$, and as $M_1 \propto LW$, we have $v \propto \frac{WL^3}{EI}$. Now this proportional equation can be shown to hold good for beams of uniform cross section and uniform depth, which may be called beams of class 2, also for beams of uniform cross section and uniform breadth, which may be called beams of class 3, hence for the three classes of beams we may write

$$7. \quad . \quad . \quad . \quad . \quad . \quad . \quad v = n\frac{WL^3}{IE},$$

where n will have different values in the three classes and for each distribution of load.

Similarly it can be proved, that where beams are so designed that the loads produce the same maximum value p_1 of the stress on the outer elements, we have the deflection proportional to $\frac{p_1L^2}{Ey_1}$,—equation 4 being one case of the general law; we may therefore write

$$8. \quad . \quad . \quad . \quad . \quad . \quad . \quad v = n_1\frac{p_1L^2}{Ey_1},$$

where n_1 is a constant differing for each class of beam and each distribution of load.

Table X. gives the values of n and n_1 for the three classes of beam, and for two distributions of load. The value of p_1 in the case of a beam of uniform cross section applies to the stress at the centre; the stresses elsewhere in that beam will be less.

TABLE X.—*Values of* n *and* n_1.

Description of Beam.	W at Centre.		W uniformly distributed.	
	n	n_1	n	n_1
Uniform strength and depth..	$\frac{1}{32}$	$\frac{1}{8}$	$\frac{1}{64}$	$\frac{1}{8}$
Uniform strength and breadth	$\frac{1}{24}$	$\frac{1}{6}$	0·0178	0·1427
Uniform cross section..........	$\frac{1}{48}$	$\frac{1}{12}$	$\frac{5}{384}$	$\frac{5}{48}$

In any actual bridge girder the deflection should lie between the value calculated for the beam of uniform strength and that calculated for the beam of uniform cross section.

§ 25. *Graphic Method of finding Deflection.*—Divide the span into any convenient number n of equal parts of length l, so that $nl = L$; compute the radii of curvature R_1, R_2, R_3 for the several sections. Let measurements along the beam be represented according to any convenient scale, so that calling L_1 and l_1 the lengths to be drawn on paper, we have $L = aL_1$; now let r_1, r_2, r_3 be a series of radii such that $r_1 = \frac{R}{ab}$, $r_2 = \frac{R_2}{ab}$, &c., where b is any convenient constant chosen of such magnitude as will allow arcs with the radii r_1, r_2, &c., to be drawn with the means at the draughtsman's disposal. Draw a curve as shown in fig. 21 with arcs of the length l_1, l_2, l_3, &c., and with the radii r_1, r_2, &c. (note, for a length $\frac{1}{2}l_1$ at each end the radius will be infinite, and the curve must end with a straight line tangent to the last arc), then let v be the measured deflection of this curve from the straight line, and V the actual deflection of the bridge; we have $V = \frac{av}{b}$, approximately. This method distorts the curve, so that vertical ordinates of the curve are drawn to a scale b times greater than that of the horizontal ordinates. Thus if the horizontal scale be one-tenth of an inch to the foot, $a = 120$, and a beam 100 feet in length would be drawn equal to 10 inches; then if the true radius at the centre were 10,000 feet, this radius, if the curve

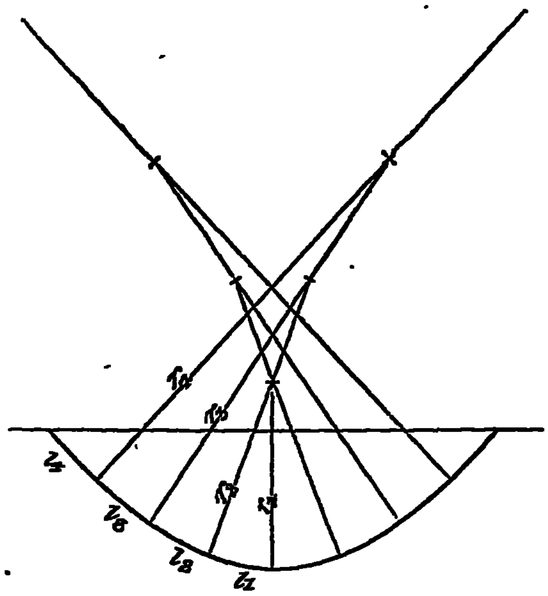

Fig. 21.

were undistorted, would be on paper 1000 inches, but making $b = 50$ we can draw the curve with a radius of 20 inches. If we now measure the versed sine of an arc drawn with a length 10 inches and a radius 20 inches, we shall approximately find it equal to 0·64 inches, hence $V = \frac{120 \times \cdot 64}{50} = 1{\cdot}54$ inches. The vertical distortion of the curve must not be so great that there is any very sensible difference between the length of the arc and its chord. This can be regulated by altering the value of b. In fig. 21 distortion is carried much too far; this figure is merely used as an illustration, and is not to be taken as an example.

§ 26. When a girder has more than two supports it is called a *continuous girder*. The distribution of the stresses in a continuous girder differs very materially from that in a simple girder, as will be at once apparent by the inspection of fig. 22, which shows the way in which a continuous

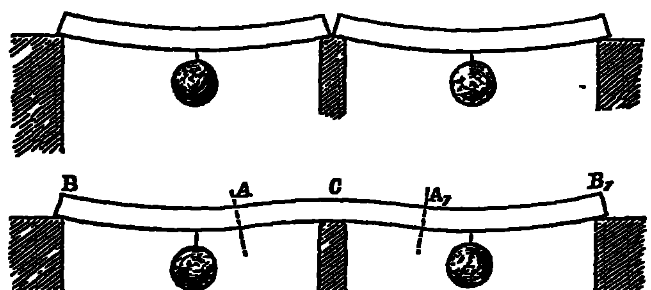

Fig. 22.

girder of two spans and two simple girders bend when employed to carry equal weights across equal openings. The continuous girder when both spans are loaded is bent upwards at C over the centre pier; in other words, the bending moment at this and neighbouring points is negative. The direction of the flexure changes at certain sections, as at A and A_1, *i.e.*, the bending moment is positive on one side of these sections, negative on the other side; and at the section where the direction of flexure changes the bending moment is *nil*. Again, when only one of two simple girders is loaded, the girder over the second span is not bent in either direction, but with the continuous girder there may be a negative bending moment produced throughout the whole unloaded span as shown in fig. 23. Con-

tinuous girders require less material for the same depth, span, and permanent load than simple girders; but the difference is hardly worth consideration, except in large

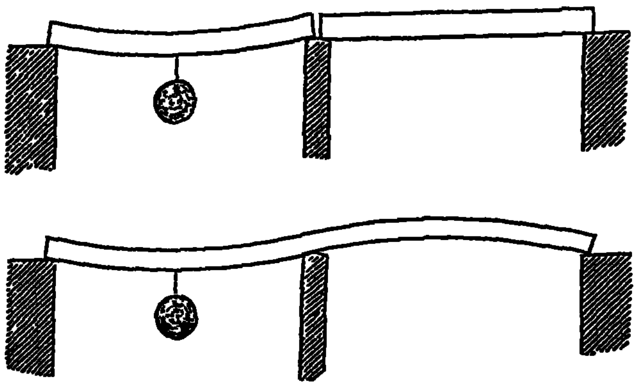

Fig. 23.

spans where the weight of the structure is great as compared with the weight of the passing load. The necessity of allowing the girder to expand and contract freely with changes of temperature limits the general use of large continuous girders to two spans.

Consider a continuous girder having an indefinite number of supports equally spaced; let the girder be of constant depth, uniformly loaded, and so proportioned as to be of uniform strength at all sections. The method of designing such a girder has not yet been shown, but it may be admitted that the design is possible. Then, as we have already seen (§ 24), the curvature assumed by the girder will everywhere be constant, *i.e.*, the curves will be circular arcs of constant radius. The points of inversion of flexure A and B (fig. 24) must therefore in this case

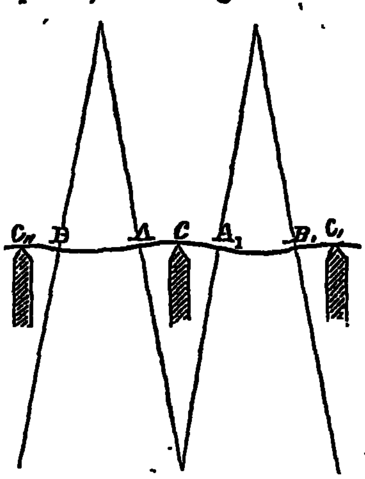

Fig. 24.

be at a distance from C and C_{11}, equal to one quarter of the span; for $AA_1 = AB = A_1 B_1$ &c., and C bisects AA_1. At B and B_1 there is no moment of flexure. The girder might here be cut through, and if the ends B and B_1 were pinned on to the rest of the girder by pins capable of bearing the shearing stress, nothing would be changed in the curvature of the girder nor in the distribution of stress. Quite similarly, we may suppose the ends B and B_1 of the portion $BACA_1B_1$ to rest directly on supports or piers introduced for the purpose, the rest of the imaginary girder being wholly removed. We shall then have (fig. 25) the curve assumed by a continuous girder of two spans of constant depth and uniform strength. The points AA_1 of inversion of flexure will be at a distance CA from the middle pier equal to one-

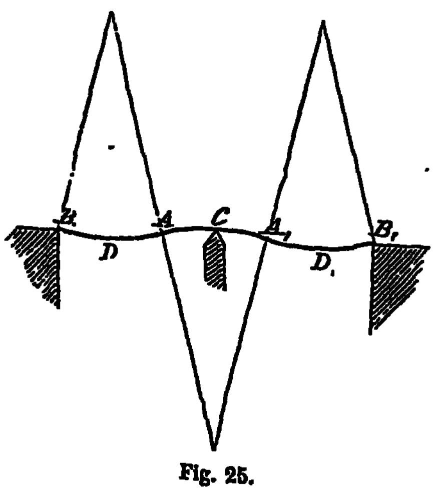

Fig. 25.

third of the span. The top and bottom members at A and A_1 might vanish (if only one distribution of load were to be carried), for at this point there is only a shearing stress and no bending moment. The girder is, as it were, made up of three girders: BA and A_1B_1 hang on to AA_1, which is supported in the middle; half the weight of AB is borne by the pier B; half the weight of A_1B_1 is borne by the pier B_1; the rest of the weight between B and B_1 is borne by the middle pier. Thus let L be the length of one span in feet, w the load per foot run, P the load borne by each of the end piers, and P_c the load borne by the centre pier, then we have—

1. . . . . $P = \frac{1}{3}wL$,
2. . . . . $P_c = \frac{4}{3}wL$.

The curve of bending moments can now be calculated for each girder precisely as for a simple girder; the moment at any section is equal to the sum of the moments of all the external forces on one side of the section; the beam between A and B will be subject to bending moments equal to those produced by a uniform load on a simple girder if the span BA be similarly loaded. Between A and A_1 the moments will be negative, *i.e.*, the left-handed moment produced by the downward action of all the weights to the left will exceed the right-handed moment produced by the upward reaction of the pier at B (or of the two piers B and C if the section considered lies to the right of C). The full black line in fig. 25*a* shows a curve of bending moments for this case.

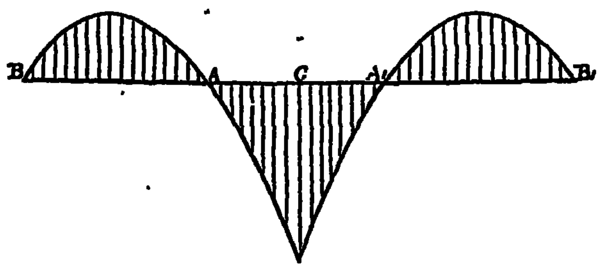

Fig. 25*a*.

The maximum moment is negative and occurs over the centre pier; let it be called M_c. The maximum positive moment occurs at a distance from B equal to one-third of the span; let this moment be M_d. Then we have—

3. . . . . . . $M_c = -\frac{1}{6}wL^2$,
4. . . . . . . $M_d = \frac{1}{18}wL^2$.

The shearing stresses F_b, F_d, F_a, F_c, at the points B, D, A, and C, are

5. . . . . . . $F_b = F_a = \frac{1}{3}wL$,
6. . . . . . . $F_d = 0$,
7. . . . . . . $F_c = \frac{2}{3}wL$.

Fig. 26 gives a diagram of the shearing stresses for two

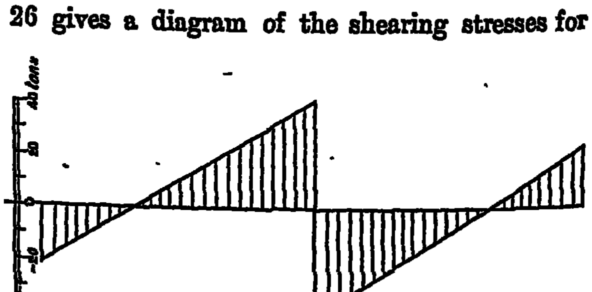

Fig. 26.

spans of 60 feet, with a uniform load of 1 ton per foot run.

When the beam is of uniform depth and uniform cross section, the curves in which it deflects are no longer circular; the defect of strength over the centre pier has

the effect of increasing the curvature over it, and shortening the distance AA_1; analysis shows that in this case the point of inversion of flexure will be at a distance from the centre pier equal to ·2683L; then the length of the part of the beam subject to a positive bending moment will be ·7317L, instead of ·66L as when the beam was of uniform strength; the load on each of the end piers will be ·36585wL; the load on the centre pier 1·2685wL; and we have—

8. . . . . $M_e = \cdot 1341wL^2$,

9. . . . . $M_d = \cdot 0669wL^2$,

10. . . . . $F_b = F_a = \cdot 36585wL$,

11. . . . . $F_d = 0$,

12. . . . . $F_c = \cdot 6341wL$

In any actual bridge uniformly loaded the values of the moments and shearing stresses will be intermediate between those given for a beam of uniform strength and those for a beam of uniform cross section. It must be observed that the above theory assumes that the girder is unstrained when being built as a whole; if, as is often the case, the separate spans are separately built and lifted into position, and then joined on the piers, special provision must be made to bring the desired bending moment over the piers into existence; it is obvious that merely joining the two independent beams in the upper part of fig. 22 will not make these into a continuous girder, such as is shown in the lower figure,—to do this, besides joining the upper and lower flanges, we must pull the top flanges together over the piers and put the lower flanges under compression. This may be done practically by tilting one end, or both ends, before the junction at the centre is made, and afterwards allowing the ends to sink until the curve assumed by the girder shows that the required distribution of stress has been attained. The complete analysis of the problem of continuous girders of any number of spans equal or unequal with any number of loads has been given by Mr Heppel (*Proc. R. S.*, 1870–71).

§ 27. *Allowance for Weight of Beam. Limiting Span.*—When the weight of the beam is a considerable and uncertain part of the whole load, it can be allowed for as follows. Design a beam of the desired depth and span, fit to carry a total load equal to the external or passing load W_1; calculate the weight of this beam and call it B_1; the beam so designed will really be fit to carry an external load $W_1 - B_1$. Let b_1 be the area of any cross section of this beam; let b be the area of cross section required at the same point for the beam of weight B actually necessary to carry a total load W. Then since the strength of the properly proportioned girder of constant depth and span is simply proportional to the quantity of metal employed, and therefore to the area of cross section, we have the proportion $b : b_1 = W_1 : W_1 - B_1$, or

1. . . . . . . $b = \dfrac{W_1 b_1}{W_1 - B_1}$.

The weight B is given by the expression—

2. . . . . . . $B = \dfrac{B_1 W_1}{W_1 - B_1}$.

The whole load W is given by the expression—

3. . . . . . . $W = \dfrac{W_1^2}{W_1 - B_1}$.

For any given design of beam there is a limiting length which cannot be exceeded (the beams of different spans being assumed to be *similar* in the geometrical sense). Let $L_{\prime}$ be the limiting length of a beam of a given design which for the span L weighs B, and carries a gross load W, then the ratio of B to W can be shown to increase in direct proportion to the length of the span until this ratio reaches unity. Hence—

$$\frac{B}{W} \cdot \frac{B_{\prime}}{W_{\prime}} = L : L_{\prime},$$

or when

$$\frac{B_{\prime}}{W} = 1,$$

4. . . . . $L_{\prime} = \dfrac{WL}{B}$.

III. Suspension Bridges.

§ 28. *Varieties of Suspension Bridges.*—A very simple form of suspension bridge has long been used in Peru and Thibet. Two ropes are hung side by side across the gorge to be passed, a rude platform is laid on the ropes, and the dip of these is sufficiently small to allow the bridge to be crossed by men or beasts passing down from the one side to the centre and up to the opposite bank. The modern suspension bridge consists of two or more *chains*, from which a level *platform* is hung by suspension *rods*. The chains may in some cases be secured directly to the sides of the chasm to be crossed, but the configuration of the ground seldom allows this to be done. The chains, therefore, usually pass over *piers*, as in fig. 2, Plate XIX., and are led down on either side to an *anchorage* at a considerable distance from the piers. The chains between the piers and the anchorage are generally used to support part of the platform. The chains where they pass over the piers rest on *saddles*, which are made of two different types. One construction, shown in fig. 27, allows the chain to slip backwards and

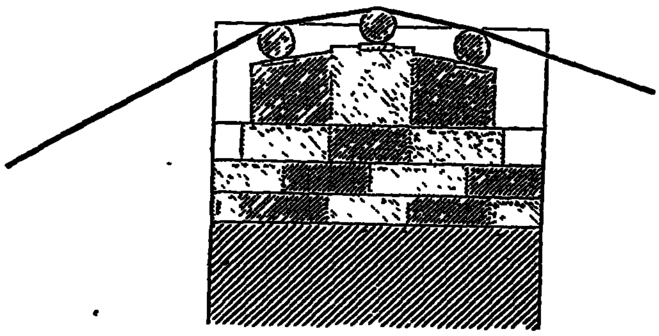

Fig. 27.

forwards over it with comparatively little friction, so that the stress on the rope may be taken as equal on both sides of the saddle. In the second type, as shown in fig. 28,

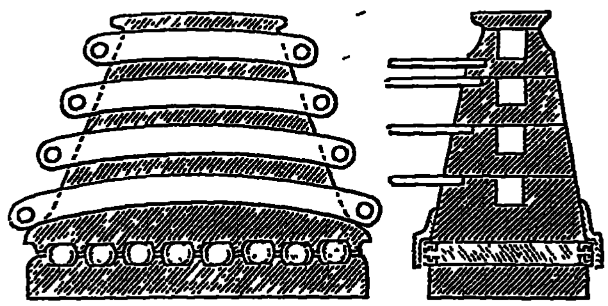

Fig. 28.

the chain is secured to the saddle, which, however, is free to move horizontally on the top of the pier. With the first form of saddle the resultant pressure on the pier will not be vertical unless the chain leaves the pier with an equal inclination on each side, and even when the bridge is designed with an equal slope of chain on both sides of the pier, a change in the distribution of weight due to any passing load will cause some departure from the equal slope of the chains, and therefore from the truly vertical pressure on the piers. This departure is easily allowed for in the design of the pier. The friction on the saddle renders the

assumption of equal stresses on each side slightly incorrect, and with this type of saddle care must be taken to provide against the wear produced by the motion of the chain. With the second type the use of rollers under the solid saddle leaves the motion of the saddle very free; the resultant pressure on the pier is always sensibly vertical, and the chains may leave the pier at any angle, equal or unequal. The chain must in no case be rigidly attached to the pier unless the support itself is free to rock on its base, as in fig. 29, where

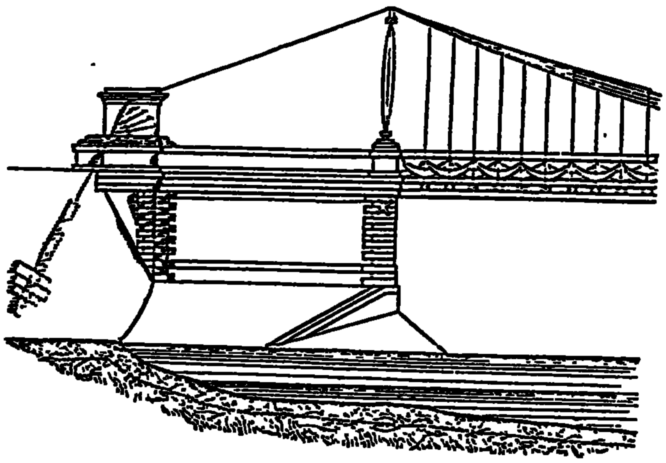

Fig. 29.

the place of the pier is taken by cast-iron struts, working on a horizontal axis.

Suspension bridges are chiefly used for very large spans, because, as we shall find, they can be constructed to carry the same load with a less weight of material than a beam or girder, subject, however, to the disadvantage of flexibility or deformation under a passing load,—a disadvantage which is very serious where, as in small bridges, the passing load is a large proportion of the whole load, but which is of less importance where the chief load to be carried is the weight of the structure itself. We will first consider the usual or simple suspension bridge, as shown in fig. 2, Plate XIX., and will then pass to the various modifications introduced to remedy its defects.

§ 29. *Form of Chain with given Load.*—Let the platform be hung from the chain by equidistant vertical rods; then the load may be treated as hanging from each joint where the rods are attached, and will consist at each joint of the weight of one subdivision of the chain and of one subdivision of the platform and its load. If the position of the vertical tie-rods be assumed as definite relatively to the points of suspension, so that the assumed loads on the joints act at known distances from the points of support, a form of chain, which will remain in equilibrium (or undisturbed) under these loads, can easily be found by the following graphic method:—

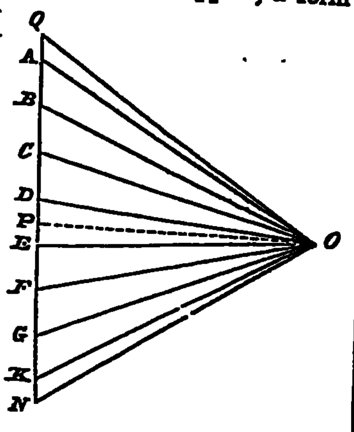

Fig. 30.

Let the vertical line QN (fig. 30) represent the whole load to be carried, and the subdivisions QA, AB, BC, CD, &c., the loads referred to each joint of the chain (QA and NK will be the portion of the load referred directly to the saddle or point of support, and will be simply half the weight of the piece of chain between the saddle and the joint pin). Let QP and NP be the weights carried by each pier,—equal if the distribution of load is symmetrical, otherwise to be determined as for a girder. Let a horizontal line, PO, represent the horizontal component of the tension to be allowed on the chain, or the whole tension on that part of the chain the tangent to which is horizontal; join O with Q, with A, B, &c.; then the lines OA, OB, &c., give the slopes of each successive link as shown in fig. 31, where the line parallel to OA in fig. 30 lies between the two spaces containing the letters O and A in fig. 31, similarly

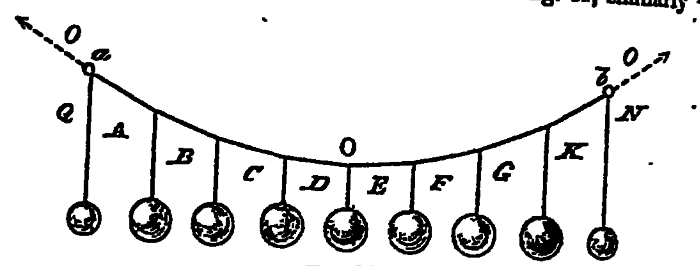

Fig. 31.

the line parallel to OB in fig. 30 is represented by the link between the two spaces lettered O and B in fig. 31, and so forth. The line in fig. 31 lying between O and Q parallel to OQ in fig. 30, represents the direction of the force on the point of support a, being equal and opposite to the resultant of the tension on the first link and the weight carried directly by the support. The triangle QOA (fig. 30) is the polygon of forces in equilibrium at the point of support a (fig. 31). The triangle OAB is the polygon of forces in equilibrium at the first joint, and similarly each component triangle of fig. 30 represents the equilibrated forces at one joint of the chain in fig. 31. This theorem is one example of the general theory of reciprocal figures, which will be treated hereafter under the general head of "Frames," § 53.

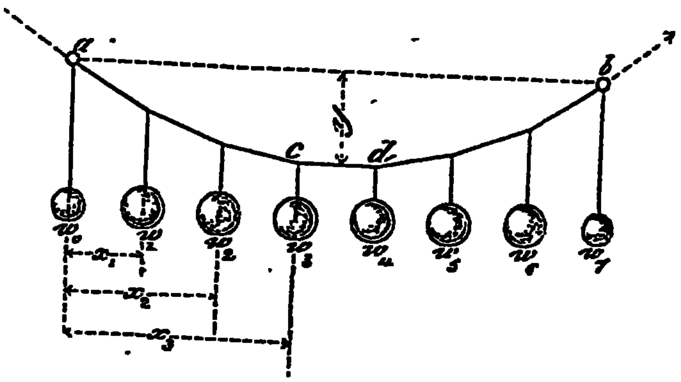

Fig. 32.

When the maximum dip is given instead of the horizontal component of the stress, it is easy to find the latter from the former by the method of moments when the point is known where the chain will be horizontal; for then, let the link cd, fig. 32, be horizontal; let the dip be called y, and let the distances of weights w_1, w_2, w_3, &c., from the point of support a be called x_1, x_2, x_3, &c., and let the horizontal tension represented by PO in fig. 30 be called H. Then taking moments round the point a, we have—

1. . . . . $Hy = \Sigma wx$,

from which H can always be found.

When the length is given of each link (or portion of the chain between the joints where the platform is suspended), and consequently the length of the whole chain, the problem of determining the form assumed under any distribution of load is difficult, for the proportion of the load carried by each pier and the position of each load relatively to the piers vary when the form of the chain varies. The problem may be solved tentatively, but it is seldom attempted.

The converse problem of finding the load which will keep a chain in equilibrium when the dimensions and curve are given is perfectly easy.

From a point O, fig. 30, draw a series of lines parallel to the given links. At any convenient distance, OP, draw a vertical line cutting the lines diverging from O at the points Q, A, B, C, D, &c. The vertical loads required to keep the chain in equilibrium are proportional to the lengths QA, AB, BC, &c.

§ 30. *Relation between the Curve of Bending Moments and the Curve assumed by a Loaded Chain.*—The vertical ordinates at the joints of an equilibrated chain, measured from a horizontal axis passing through the two points of support (these being at the same level), are proportional to the bending moments for similarly chosen sections of a girder similarly loaded.

Let us consider any joint, say that at which w_3 is hanging in fig. 33. Let V be the vertical component of the resultant pull on the left

hand pier, and H the horizontal component. We know that the vertical component is equal to the whole reaction at the pier

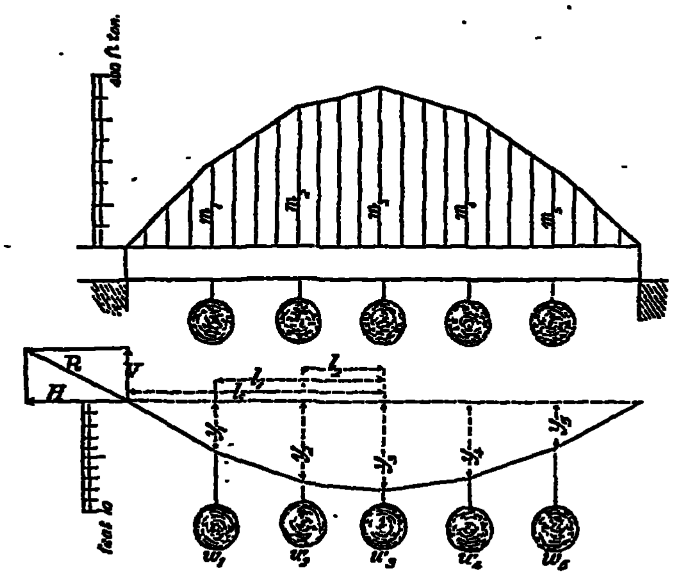

Fig. 33.

when the same load is carried by a girder; then, taking moments about the joint in question, we have—

1. . . . . . $Hy_3 = Vl_0 - w_1l_1 - w_2l_2$,

but the second member of the equation is the bending moment m_3 for the section at a distance l_0 from the pier in a girder of similar span and similarly loaded, therefore, whatever may be the value of H, the values of y_1, y_2, y_3, &c., are proportional to the bending moments. If, then, a curve of bending moments with the ordinates m_1, m_2, m_3, &c., be drawn for a given distribution of load, we can, with a pair of proportional compasses, construct any number of equilibrated curves, by making the values of y in these curves simply proportional to the values of m in the curve of bending moments, and by selection among these a curve of any required length may be found. If H be unity, the ordinates y_1, y_2, y_3, &c., are equal to the bending moments.

§ 31. *Chain Loaded uniformly along a Horizontal Line.*—If the lengths of the links be assumed indefinitely short, the chain under given simple distributions of load will take the form of comparatively simple mathematical curves known as catenaries. The true catenary is that assumed by a chain of uniform weight per unit of length, but the form generally adopted for suspension bridges is that assumed by a chain under a weight uniformly distributed relatively to a horizontal line. This curve is a parabola.

From equation 1, § 30, remembering that Σwl in this case will be equal to $\frac{wL^2}{8}$, we see that the horizontal tension H at the vertex for a span L (the points of support being at equal heights) is given by the expression—

1. . . . . $H = \frac{wL^2}{8y}$,

or, calling x the distance from the vertex to the point of support,

$$H = \frac{wx^2}{2y}.$$

The value of H is equal to the maximum tension on the bottom flange, or compression on the top flange, of a girder of equal span, equally and similarly loaded, and having a depth equal to the dip of the suspension bridge.

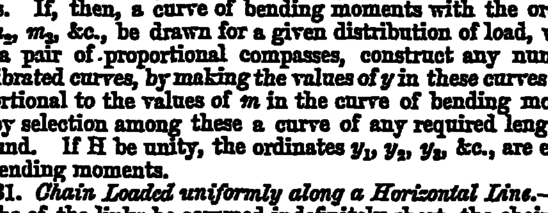

Fig. 34.

Consider any other point F of the curve, fig. 34, at a distance x from the vertex, the horizontal component of the resultant (tangent to the curve) will be unaltered; the vertical component V will be simply the sum of the loads between O and F, or wx. In the triangle FDC, let FD be tangent to the curve, FC vertical, and DC horizontal; these three sides will necessarily be proportional respectively to the resultant tension along the chain at F, the vertical force V passing through the point D, and the horizontal tension at O; hence

$$H : V = DC : FC = \frac{wx^2}{2y} : wx = \frac{x}{2} : y,$$

hence DC is the half of OC, proving the curve to be a parabola.

The value of R, the tension at any point at a distance x from the vertex, is obtained from the equation—

$$R^2 = H^2 + V^2 = \frac{w^2x^4}{4y^2} + w^2x^2,$$

or,

2 . . . . . . $R = wx\sqrt{1+\frac{x^2}{4y^2}}$

Let i be the angle between the tangent at any point having the co-ordinates x and y measured from the vertex, then

3. . . . . $\tan i = \frac{2y}{x}$.

Let the length of half the parabolic chain be called s, then

4. . . . . $s = x + \frac{2y^2}{3x}$.

The following is the approximate expression for the relation between a change Δs in the length of the half chain and the corresponding change Δy in the dip:—

$$s + \Delta s = x + \frac{2}{3x}\left\{y^2 + 2y\Delta y + (\Delta y)^2\right\} = x + \frac{2y^2}{3x} + \frac{4y\Delta y}{3x} + \frac{2\Delta y^2}{3x},$$

or, neglecting the last term,

5. . . . . $\Delta s = \frac{4}{3}\frac{y\Delta y}{x}$

and

6. . . . . $\Delta y = \frac{3}{4}\frac{x}{y}\Delta s$.

From these equations the deflection produced by any given stress on the chains or by a change of temperature can be calculated.

If the points of support are not at equal height (fig. 35) call the heights above the vertex y and y_1, and the horizontal distances of

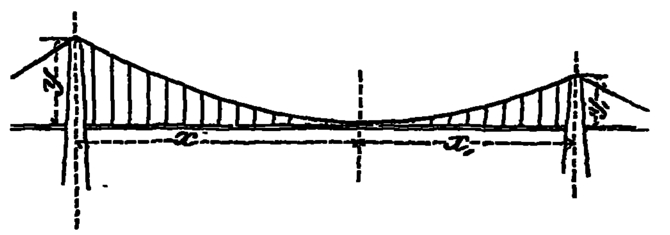

Fig. 35.

the vertex from the points of support x and x_1; let y and y_1 be given, and x, x_1 unknown.

The horizontal stress at the vertex will be the same as if the bridge were composed of two symmetrical halves, each having a span $2x$ and a dip y, or of two symmetrical halves, with a span $2x_1$ and a dip y_1; in other words—

$$H = \frac{wx^2}{2y} = \frac{wx_1^2}{2y_1},$$

hence

7. . . . . $\frac{x^2}{y} = \frac{x_1^2}{y_1}$,

or,

$$x : x_1 = \sqrt{y} : \sqrt{y_1};$$

thus, to find the horizontal position of the vertex, we have only to subdivide the span in the ratio $\sqrt{y} : \sqrt{y_1}$; we may then calculate the strains on one side of the vertex as for half a bridge with the span $2x$ and the dip y, and on the other side of the vertex as for half a bridge with the span $2x_1$ and the dip y_1. The device of piers of different heights may be used with advantage when it is desired to throw a larger portion of the weight of the bridge on one pier than the other, because of a difference in the soundness of the foundations, or for other reasons. The stresses on the loaded and unloaded portion of the chains between the piers and the anchorage are easily determined by methods similar to those which have been given for the stresses on each part of the main span. The same methods also give the direction of each successive link, and of the final links leading to the anchorage.

§ 32. *Practical Details.* — The chains of suspension bridges are either long wire ropes or true chains made of links pinned together. Wire ropes allow the strongest known material to be adopted, namely, steel wire, which

can be bought in large quantities of a quality which does not break with less than a stress of from 55 to 60 tons per square inch of section; charcoal iron wire of the sizes used will bear 40 tons per square inch; common sizes of wire for the purpose are from 0·16 to 0·14 inches, or say, No. 9 or 10 Birmingham wire gauge. Three or four thousand wires are not unfrequently used in one cable, and it is very essential that each wire shall take an equal part of the whole stress. It used to be thought necessary to ensure this by straining each wire separately either over the actual piers, or piers similarly placed, and binding them together when hanging, strained by their own weight with the dip proposed for the bridge. It was also thought essential that each rope should be an aggregate of parallel wires, not spun as in a hempen rope. Experiment has shown, however, that wire ropes spun with machines which do not put a twist into each wire, but lay it helically and untwisted, and with no straight central wire, are as strong as wire ropes of equal weight made with straight wires. They are, however, much more easily made. A number of ropes of this kind may, therefore, with more convenience and economy be bound together into one cable in the manner previously practised for single wires. Care should be taken to fill every interstice of the ropes with a bituminous compound.

When the chains are made of links of iron their ultimate strength cannot be taken as more than 30 tons per square inch, even if the very best material is secured. It is doubtful if this ultimate strength can at present be surpassed by steel links, for although many steel links of greater strength could certainly be obtained, occasionally a comparatively weak link will be produced even by the

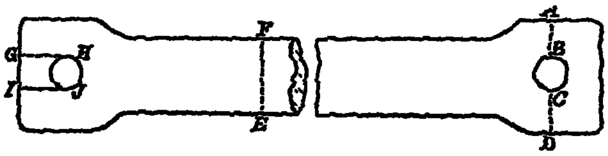

Fig. 36.

best manufacturers. In designing the links care must be taken to provide sufficient cross section at the eye, AB+CD, fig. 36, as well as at EF. The diameter of the pin BC must be such as will allow it to resist the shearing stress on it, and the surface of the pin and eye from B to C must be sufficient to bear the crushing stress. Otherwise, although the pin may not be shorn it may be squeezed flat, and the head of the link may bulge out and be much distorted under the stress. To obtain the necessary surface, without unduly increasing the diameter of the pin, the link may be rolled with a head

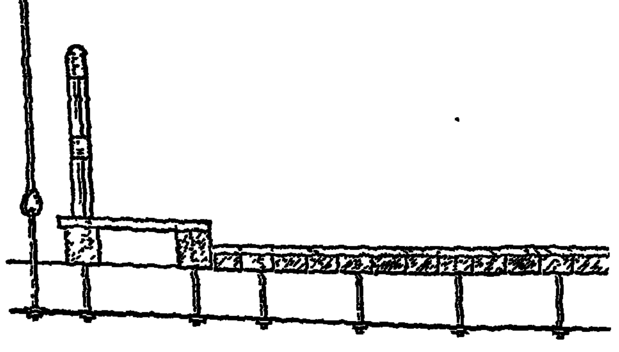

Fig. 37.

broader than the body of the link. The section at GH and IJ must also be sufficient to resist shearing. When two or more parallel chains are used, care must be taken that the rods suspending the platform bear equally on the several chains. Fig. 37 shows a plan of securing this. Chains of unequal dip should not be used to support one platform, for the strain cannot be equally divided between them, inasmuch as they must deflect unequally with any passing load, or with any increase of temperature.

§ 33. *Merits and Defects of Suspension Bridges.*—The great merit of a suspension bridge is its cheapness, arising from the comparatively small quantity of material required to carry a given passing load across a given span. This merit may be easily seen by considering an elementary example. A man might cross a chasm of 100 feet hanging to a steel wire 0·21 inches in diameter, dipping 10 feet; the weight of the wire would be 12·75 ℔. A wrought iron beam of rectangular section, three times as deep as it is broad, would have to be about 27 inches deep and 9 inches broad to carry him *and its own weight.* It would weigh 87,500 ℔. An iron I beam of the best construction, 10 feet deep, would weigh about 120 ℔, without allowing anything for the stiffening of the centre web which would in practice be required. In each case four feet in length have been allowed for bearings at the ends of the span. The enormous difference would not exist if the beam and wire had only to carry the man, although even then there would be a great difference in favour of the wire; the main difference arises from the fact that the bridge has to carry *its own weight.* The chief merit of the suspension bridge does not, therefore, come into play until the weight of the rope or beam is considerable when compared with the platform and rolling load; for although the chain will for any given load be lighter than a beam, the saving in this respect will for small spans be more than compensated by the expense of the anchorages. In large spans the advantage of the suspension bridge is so great that we find bridges on this principle of 800 or 900 feet span constructed at much less cost per foot run than girder bridges of half the span. The disadvantages of the suspension bridge are, however, very great. A change in the distribution of the load causes a very sensible deformation of the structure; for the chain of the suspension bridge must adapt its form to the new position of the load, whereas in the beam the deformation is hardly sensible, equilibrium being attained by a new distribution of the stresses through the material. This flexibility of the suspension bridge renders it unsuitable for the passage of a railway train at any considerable speed. The platform rises up as a wave in front of any rapidly advancing load, and the masses in motion produce stresses much greater than those which could result from the same weights when at rest; moreover, the kinetic effect of the oscillations produced by bodies of men marching, or even by impulses due to wind, may give rise to strains which cannot be foreseen, and which have actually caused the failure of some suspension bridges. On the 16th of April 1850 a suspension bridge at Angers gave way when 487 soldiers were passing, and of these 226 were killed by the accident. Another danger peculiar to suspension bridges is that the platform may be lifted by the wind, when its oscillation will produce most dangerous strains. This accident may be prevented by tying the platform down to the piers or abutments. Lateral oscillation produced by the wind is also dangerous, and even gathered ice and snow may be a serious increment to the load on these bridges, forming a much more considerable fraction of the whole weight than where the supporting structure is itself massive. Suspension bridges must be well cross-braced to resist the action of the wind. They can be much stiffened laterally by placing the chains in inclined planes, converging downwards to the platform.

§ 34. *Modifications of the Simple Suspension Bridge.*—Many efforts have been made to design a bridge which

shall combine the lightness of the true suspension bridge with the stiffness of the girder. Mr Dredge's design with sloping rods (fig. 38) gives a somewhat stiffer structure

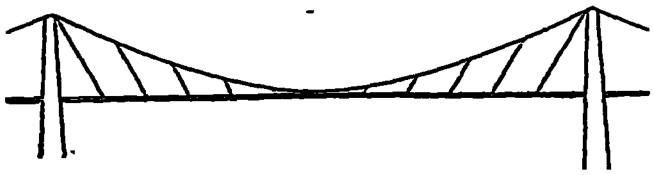

Fig. 38.

than the bridge with vertical suspension rods; the inclined rods throw a strain on the platform, which must be resisted either by ties along the central portion, or by struts abutting against the piers. The stresses on each part will be shown under the heading "Compound Structures" (§ 62).

The design fig. 39 has been proposed by many, but is

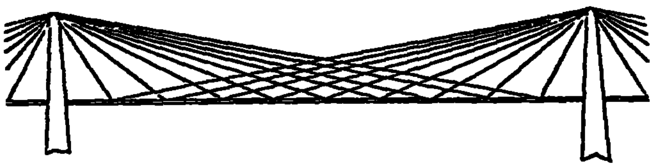

Fig. 39.

worthless. The object of the proposers is to support each part of the platform by rods which are quite independent of other parts of the structure, and which, being originally straight, do not alter their form under stress. The unequal stretching of the long and short rods under a stress, or with a rise of temperature, is a radical defect. Mr Ordish has proposed a plan in which the road is supported by sloping tie rods, arranged like the struts in fig. 87, inverted. Flexible chains, like that of an ordinary suspension bridge, carry the weight of these tie rods by vertical rods, which keep the sloping rods straight. The chain in this form is not subjected to unequal loading. Various forms of bridge have been proposed, in which, as in figs. 76 and 78, two chains are braced together. These may be made thoroughly stiff bridges, with a moderate increase in the amount of metal required for the flexible bridge. They will be described under the head of "Frames." Stiffness has also been obtained in some structures by using an auxiliary girder to stiffen the platform. This is best effected by the use for each chain of two girders, each half the length of the platform. These girders are placed as in fig. 40, being hinged together by a strong pin at B, and

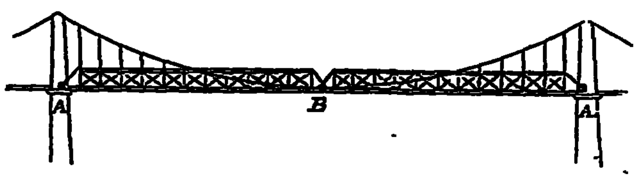

Fig. 40.

held down by pins at A and A_1, which should, however, be left free to move horizontally. These girders are not sensibly strained by the rise and fall of the chains due to a fall or rise of temperature; they can also deflect freely as a whole when the chain is deflected under strain; nevertheless, they serve to distribute the weight of a passing load over the chain, so that it cannot be sensibly distorted. Rankine has given the following rule for designing these stiffening girders. Let w_1 be the greatest rolling load per foot run; let x be the half span of the chain; let M be the greatest bending moment which the auxiliary girders will have to resist (*i.e.*, at the centre of each); let F be the greatest shearing force (at the end and central pins), then

1. . . . . . . $M=\frac{1}{16}w_1x^2$,

and

2. . . . . . . $F=\frac{1}{4}w_1x$.

Each auxiliary half girder is in fact to be designed as a beam of half the span of the bridge, and capable of carrying half the passing load per foot run (but not its own weight). This plan of stiffening is quite effective, but adds considerably to the weight and cost of the whole structure; for not only have we to provide these extra girders, but extra material in the chains to carry this extra dead load.

§ 35. *Maximum Span.*—If we assume that wire can be obtained which will safely bear 15 tons per square inch, a rope (or single wire) with a dip of $\frac{1}{12}$th of the span would safely bear its own weight over a span of about one mile, and would not break till the span exceeded 4 miles. With a dip of $\frac{1}{7}$th of the span a steel wire rope of the best quality would not break until the span exceeded 7 miles. These lengths are not given as indicating practical spans for bridges, but to show the limits which with our present materials cannot be exceeded, however light the passing load may be.

IV. The Arch.

§ 36. *General Description.*—An arch may be of stone, brick, wood, or metal. The oldest arches are of stone or brick. They differ from metal or wooden arches, inasmuch as the compressed arc of materials called the *ring* (fig. 41, London Bridge), is built of a number of separate pieces

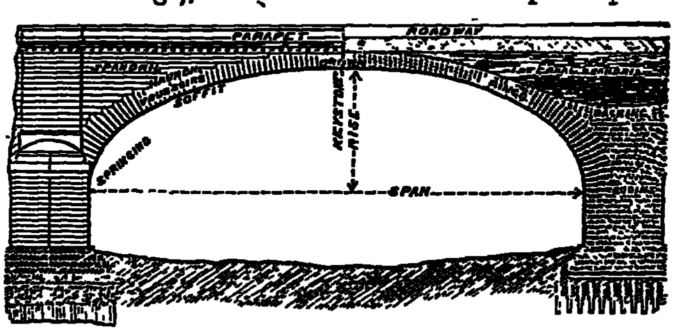

FIG. 41.—Half Elevation and Half Section of Arch of London Bridge.

having little or no cohesion. Each separate stone used in building the *ring* has received the name of *voussoir*, or archstone. The lower surface of the ring is called the *soffit* of the arch. The *joints*, or bed-joints, are the surfaces separating the voussoirs, and are normal to the soffit. A brick arch is usually built in numerous rings, so that it cannot be conceived as built of voussoirs with plane joints passing straight through the ring. The bed-joints of a brick arch may be considered as stepped and interlocked. This interlocking will affect the stability of the arch only in those cases where one voussoir tends to slip along its neighbour. The ring springs from a course of stones in the abutments, called *quoins*. The plane of demarcation between the ring and the abutment is called the *springing* of the arch. The *crown* of the arch is the summit of the ring. The voussoirs at the crown are called *keystones*. The *haunches* of the arch are the parts midway between the springing and the crown. The upper surface of the ring is sometimes improperly called the extrados, and the lower surface is more properly called the intrados. These terms, when properly employed, have reference to a mathematical theory of the arch little used by engineers. The walls which rest upon the ring along the arch, and rise either to the parapet or roadway, are called *spandrils*. There are necessarily two outer spandrils forming the faces of the bridge; there may be one or more inner spandrils. The *backing* of an arch is the

masonry above the haunches of the ring; it is carried back between the spandrils to the pier or abutment. If the backing is not carried up to the roadway, as is seldom the case, the rough material employed between the backing and the roadway is called the *filling*. The *parapet* rests on the outer spandrils. The abutments and piers have the same signification as in other bridges. The masonry arch differs from the superstructure of other bridges in the following respect: it depends for its stability on the presence of a permanent load specially arranged, and so considerable in amount that the changes produced in the direction and magnitude of the stresses by the passing load are insignificant. The theories of the masonry arch often neglect the passing load entirely, and simply teach the student how to distribute the permanent load, so that the voussoirs may be in equilibrium. The permanent load consists of the ring, the backing, the filling, the spandrils, and the roadway. Inasmuch as the ring is that part of the structure which by its special strength and arrangement carries the superstructure in the same sense as a beam or chain carries it, the arch in this article will be treated simply as a ring of voussoirs springing from two abutments and loaded with weights, some permanent and some passing. Where the backing strengthens the arch, it becomes virtually part of the ring.

§ 37. *Equilibrium of a Single Voussoir.*—A block, such as a voussoir, ABCD, fig. 42, resting on one of its surfaces, such as the joint AB separating it from the next voussoir, is in equilibrium when the resultant of all the forces acting upon it (including its own weight) falls within the supporting surface, while the direction of this resultant makes an angle ϕ with the normal to the surface less than the angle of repose; (the tangent of the angle of repose is the coefficient of friction).

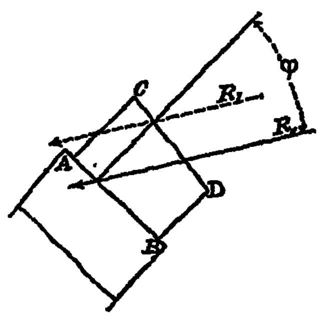

Fig. 42.

If the resultant, as $R_{\prime}$, falls without the surface, the block will heel over, pivoting on the edge A. If the resultant, as $R_{\prime\prime}$, although falling within the surface of which AB is the trace, is yet much inclined to the normal, the block ABCD will slide up on the joint AB without heeling over. The block, if used as the voussoir of a bridge, must not only be in equilibrium under the forces applied to it, but must also be of sufficient strength to resist these forces. The intensity of crushing stress due to the external forces must nowhere exceed the safe crushing strength of the material. This latter condition would in most arches be fulfilled by an extremely thin ring of stones or brick if the resultant passed through the geometrical centre of the joint AB in a direction normal to it. In that case the stress on the joint would be a uniformly distributed stress; if, however, the resultant stress passes near one edge, the intensity of stress at that edge will be much greater than elsewhere, and would indeed be infinite if the resultant passed exactly through the edge at A or B; while, therefore, the condition of equilibrium is satisfied if the resultant passes within either edge of the voussoir at no great inclination, the condition of strength requires that this resultant shall not cut the joint very near the edge, and the common practical rule is that it shall always fall within the middle third of the joint. This rule is based on the condition that the pressure on a joint shall nowhere be negative; in other words, that no tension shall occur at any part of any joint. The principles explained in § 8 show that the minimum stress on any joint $p_1 = p_0 - \frac{Px_0x_1}{I}$, or that the stress will be zero, when $p_0 = \frac{Px_0x_1}{I}$. Let d be the depth of the rectangular joint, and b the breadth; then

$$I = \frac{bd^3}{12}, \text{ and } x_1 = \frac{d}{2}, \text{ and } p_0 = \frac{P}{bd};$$

hence

$$\frac{P}{bd} = \frac{12Px_0d}{2bd^3}, \text{ or } \frac{d}{6} = x_0,$$

an equation expressing the condition that the centre of pressure lies at the edge of the middle third; any greater value of x_0 will give a negative value to p_1. We shall see that the actual resultant is, according to the theory practically in use, indeterminate within certain limits; it is therefore useless to attempt to calculate the exact maximum stress on any one stone. In the rest of this article the *ring* is to be held to mean the *middle third* of the actual masonry, or brick ring, wherever the theory requires that the blocks are to resist practical loads. As bridges are subject to a sensibly equal load on all parts of their breadth between the parapets, it is usual to consider a portion of the ring one foot in width, each other strip being under precisely similar conditions. Similarly the joint may be spoken of for convenience as the line which is its trace, and the edge as the point which is its trace.

The external forces which act on any voussoir are—1st, the vertical force, being the resultant of its own weight and the load which is directly over it; 2d, the thrust from the voussoir above it; and 3d, the reaction from the voussoir on which it rests (fig. 43). It is sometimes difficult to determine exactly what portion of the superincumbent load a voussoir may properly be said to carry, but a sufficient approximation is obtained for practical purposes by assuming that the mass vertically above any voussoir is carried by the voussoir when the back of the voussoir is not much inclined. If the materials had little cohesion, the direction of the force produced by the load would not be vertical, but inclined at an angle depending on the coefficient of friction; in practice, the direction of the force is uncertain and even variable with changes in the condition of the superincumbent filling. If, however, the stability of the arch is calculated with a reasonable margin or coefficient of safety, on the hypothesis that the force produced by the load is vertical, there is every probability that the arch will be stable under any actual stress which may arise in practice.

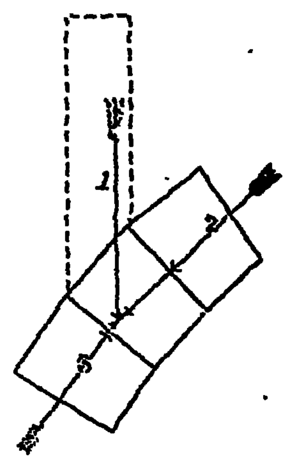

Fig 43.

§ 38. *Equilibrium of any three Voussoirs; Equilibrated Polygon.*—The simplest arch would be an arch of three voussoirs resting on two abutments, and any actual arch consisting of many voussoirs may be considered as composed of successive triplets, the voussoirs on each side of which act as abutments. If, therefore, we can show the conditions of equilibrium for three voussoirs we shall have determined the conditions for the whole ring.

Let three voussoirs be taken from any part of the ring (fig. 44), and let the lines 1, 2, and 3 represent the position of the resultants of the three known loads w_1, w_2, and w_3 (including the weight of the voussoirs) borne by each voussoir.

Let NA represent the position of the reaction t due to the abutting voussoir on one side. Let A be the point where the prolongation of the line NA cuts the line 1; then if the magnitude of the

forces t and w_1 are known, these determine the magnitude and direction of the equilibrating force t_1, which must act at A to balance them. Let the direction AB and the magnitude of the force t_1 be

Fig. 44a.

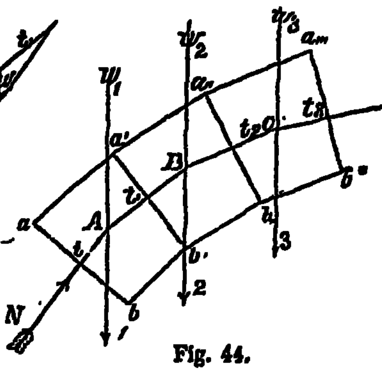

Fig. 44.

found by the ordinary parallelogram of forces, as in fig. 44a, and let B be the point of intersection of the direction of this force with the line 2; then the direction and the magnitude of the equilibrating force t_2 can be found as for t_1; similarly the direction of this force gives the point C by its intersection with the line 3, and finally we obtain, by the resolution of forces, the direction, magnitude, and position of the force t_3, by means of which the reaction of the second abutment will keep the system in equilibrium. When the position and magnitude of t are known, the position and magnitude of all the other forces are determinate; the conditions of equilibrium are that *the lines NA, AB, BC, and CQ, shall not cut the joints above* or below the edges a or b, for in that case the blocks would heel over on the edge beyond which the resultant passed; also, the direction of the lines NA, AB, &c., must be such as not to exceed the angle of repose with the normal to the *joints, otherwise* one stone will slip on the other. The abutment producing by its reaction the force t_3 must not yield with a less force than t_3, and must not be pushed forward so as to produce a greater force than t_3. The line NABCQ, if inverted, is in form identical with that which a cord would assume, loaded at the points A, B, and C, with the loads 1, 2, and 3, and having the direction of NA determined. This line will, in the rest of this article, be called an *equilibrated polygon*.

When the joints are supposed indefinitely near, or the voussoirs thin sheets, the equilibrated polygon becomes a curve called a *linear arch*.

The reasoning applied to three blocks is clearly applicable to any number, and we may therefore say that any series of loaded voussoirs will be in equilibrium when a reaction of known magnitude and direction is applied at one abutment, provided the equilibrated polygon required by this reaction and the given loads can be drawn so that its sides cut all the joints within the ring (or within the

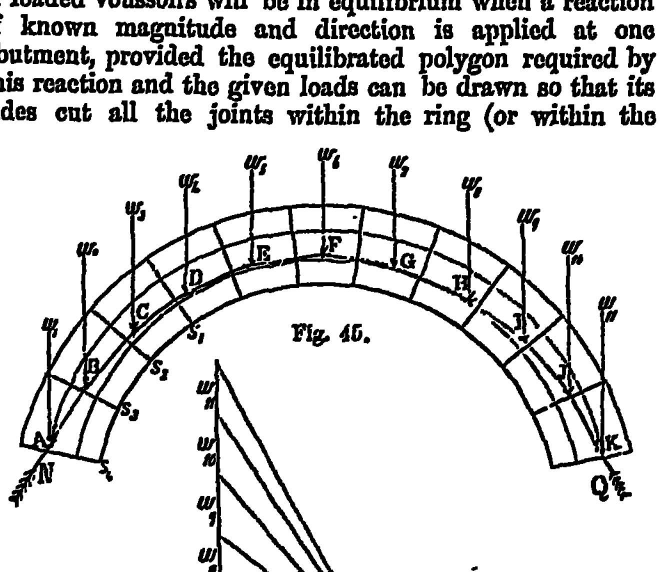

Fig. 45.

Fig. 45a

middle third, where strength is an element of the question*)* *at an angle greater than the complement of the angle of* repose for the material used. An equilibrated polygon, ABC... ..Q, for a complete arch is shown in fig. 45 Fig. 45a is the diagram giving the slopes KJ, JI, &c., as for the loaded chain fig. 30 and 31.

§ 39. *It will be shown in next paragraph that the arch* will be in equilibrium if with any value of the horizontal thrust h an equilibrated polygon can be drawn fulfilling the conditions required. In most arches equilibrated polygons fulfilling these conditions can be drawn with values of h *varying between two limits differing* by a considerable amount. In that case the smallest value of h will be the true value, and give the true stresses; for the abutments being inert will not give back a greater thrust than is just required to balance the structure. This would render the thrust h determinate if the equilibrated polygon might actually approach the true edge of the ring, but as this would require infinitely strong materials, we are still left in uncertainty as to the true value of h, but may feel sure that it will be the smallest value consistent with a safe stress on the material. If we provide abutments capable of reacting with a force h sufficient to keep the equilibrated polygon (where it cuts the joints) within the middle third, our abutment will certainly be amply strong enough, and this is the value of h to be adopted in all practical calculations of the stability of an arch.

In the example with the three voussoirs it is clear that equilibrium would be obtained with very widely different reactions t at the one abutment. And this fact is also true for a bridge of many voussoirs. The vertical component (which may be called v) *of this total thrust t is* indeed determinate if we suppose the point where t cuts *the joint to be known, being the same as the vertical reac*tion from a beam carrying the same weights and supported at the points where t and v cut the abutments; but the horizontal component or horizontal thrust, which has been called h, cannot be determined by any considerations hitherto mentioned.

§ 40. *Experimental Demonstration that the Equilibrium of a series of Voussoirs is stable if any Equilibrated Polygon can be drawn fulfilling the conditions stated above.*—Let us suppose an arch, fig. 48, to be constructed, the bed-joints of which are not plane but curved, so that each stone touches its neighbour only along a horizontal line, the trace of which in a drawing may be called the *point of contact.* Such an arch will differ from an ordinary arch in this respect, that the centre of pressure at joints will be shown by the points of contact, while the stones will be able by rolling to alter the points of contact if not in equilibrium. In such an arch the voussoirs in the first place may be put together so as to touch at any desired series of points, but the forces called into play when external support is withdrawn will rearrange the voussoirs so as to bring them into equilibrium, if any equilibrated arch consistent with the loads can be drawn so that the lines forming it cut the joints inside the ring, and a model will show the points of contact, or, in other words, the places where these lines cut the joints. (It is assumed that the obliquity of the sides of the polygon to the joints which they cut is insufficient to produce slipping.)

An actual model shows the action very prettily, but the following considerations will easily allow the student to see how it is that the voussoirs always arrange themselves so as to build a true arch.

Suppose, first, that the arch consisted merely of three stones, fig. 46, and that the weight on the centre one was so great that the linear arch, or equilibrated polygon, became sensibly two inclined straight lines like rafters. As soon as the voussoirs are left to themselves, the pressure at the surface a_2 b_2, and the reaction at the surface a_1 b_1, will lie in one straight line, which, *meeting a similar* straight line from the other abutment, will give one equilibrated polygon, satisfying the required conditions; but if the horizontal force required for this polygon is not supplied by the abutments, the two *forces* at joints 1 and 2 will, as shown by the small straight arrows, constitute a couple tending to turn the stone A round, so that the point of contact at joint 1 will be lower, and the point of contact in joint 2 will be higher than before. The same action will occur in stone C, and the result will be that the weight may be balanced with a smaller horizontal force. At the

same time the rotation of the stones A and C, coupled with the descent of B, tends to push back the abutments N and Q, and therefore to increase their horizontal reaction supposing them to be stable. If the abutments N, Q continue to yield, the stones A

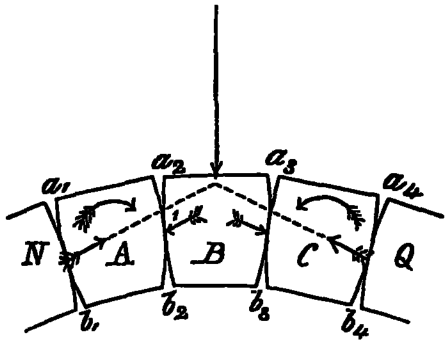

Fig. 46.

and B will continue to turn until the points of contact reach a_2 and a_3, or b_1 and b_4. The horizontal thrust which the abutments require to meet will therefore diminish as the stones turn, and the little structure will only fail to support the weight in case the abutments N and Q are insufficiently strong or stable to supply the minimum thrust consistent with an equilibrated polygon

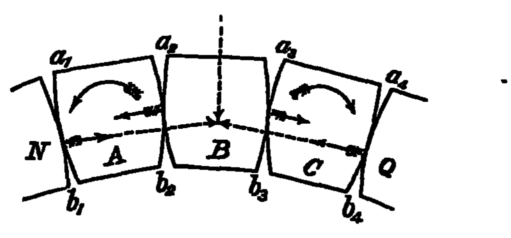

Fig. 47.

cutting the joints inside the ring (or in case the polygon cut the joints at such an angle that the stones slip). If, on the other hand, the abutments were so made as to press in upon A and C with a greater horizontal force than is consistent with two lines of pressure passing through the actual points of contact, then, as in fig. 47, the direction of the couples on the stones A and B would be reversed, and they will roll round so as to bring the points of contact more nearly into the position required to meet an excessive horizontal thrust, and at the same time the changed position of the stones, by allowing N and Q to come forward, will tend to relieve or diminish the original excessive horizontal thrust, where this is due to the elasticity of the stones N and Q, or of the stones supporting these abutments. The structure will not fail unless the points of contact reach a_1 and a_4, or b_2 and b_3, when the structure would fail by the sides being squeezed in, and the stone B being lifted up out of the arch. This could not happen with stones of the proportions shown in fig. 47, as before the limiting position was reached, the points of contact would lie on a straight line corresponding to an infinite horizontal thrust. In conclusion we see that, whether the horizontal force supplied by the reaction of the abutting stones be too small or too great, the three voussoirs tend to move so as to adapt the centre of pressure and the actual horizontal force to one another. The equilibrium produced is stable, that is to say, if by some external force the arrangement of the blocks is slightly disturbed, when the force is removed the blocks return to their original position. In the above demonstration it is assumed that the blocks when first put together touch at some point not far from the centre of the bed,—a condition corresponding to reasonably good fitting in the case of the plane joints of a stone arch before the centring is removed.

If a model be prepared (fig. 48), having a number of voussoirs of wood with their bed-joints slightly curved and roughened, the result of the above theory will be very clearly and beautifully seen. The action explained in the case of three blocks holds good for any three, and therefore for the whole series. If an additional weight is placed at the crown, as in fig. 48, the crown is a little lowered, but the curve passing through the lines of contact rises at the crown and is lowered at the haunch by the rotation of the blocks, until the lines of contact at the joints arrange themselves, so that the resultant pressures forming the imaginary polygon pass through these lines of contact. If the extra load be placed at the haunches the crown rises, but the points or lines of contact between the voussoirs are lowered at the crown and raised at the haunches, as in fig. 48a. If one haunch only is weighted, the curve passing through the lines of contact rises at that haunch and is lowered at the other, as in fig. 48b; if the model be distorted by the hand it oscillates up and down on each side of the position of equilibrium, as a string similarly loaded would do. Figures 48, 48a, and 48b are taken from photographs of a model. (It should be remarked that the abut-

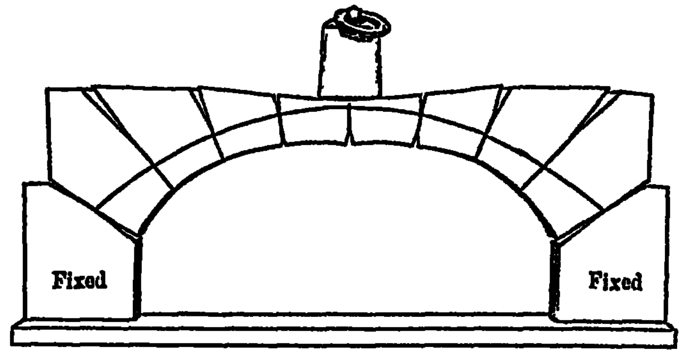

Fig. 48.

ments were screwed to the supporting board; it is obvious that otherwise they would not have been in equilibrium.) The general character of the curve passing through the points of contact may be easily conceived by thinking of a string similarly loaded and

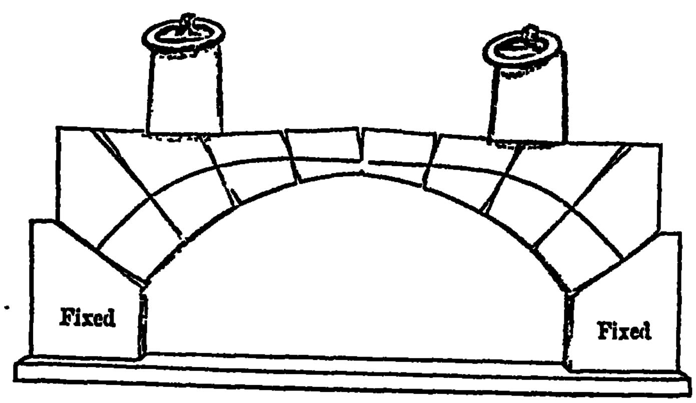

Fig. 48a.

inverted. The equilibrated arch will be one of those forms which a string might take when similarly loaded, but when the load is changed, the length of the curve will not be constant in the arch, whereas it must be constant with any given chain. The curve pass-

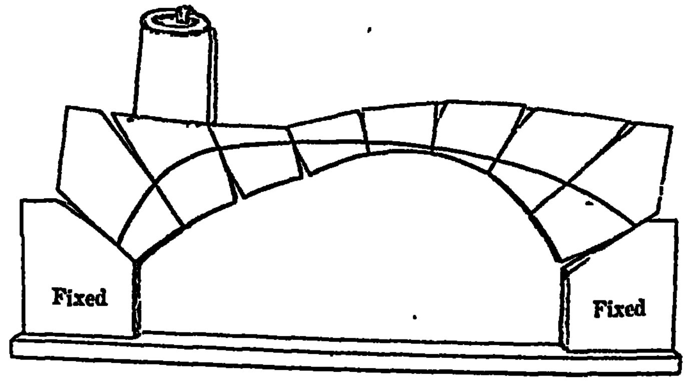

Fig. 48b.

ing through the points of *contact* corresponds with what Moseley called the line of resistance. The direction of the pressure is not necessarily tangent to this curve, but in the ordinary form of bridge it is nearly so.

In the model each voussoir is free to roll, because the bed-joints are curved. In an actual bridge the bed-joints are plane, nevertheless, the stones do turn round to adapt themselves to the pressure, but the result of this rotation is to render the compression along the upper and lower halves of the stone unequal. One edge is more compressed than the other; the couple tending to turn the voussoir, and actually allowed to do so in the model, is met by an equal and opposite couple, due to the unequal compression of the stone.

This couple is the necessary result of a pressure which is not axial, *vide* § 8; an equilibrated polygon cutting the joints at various distances from the centre is therefore as correct an indication of the actual forces present in a practical arch with flat joints as in the model with curved joints; but we must remember that where the joints are flat, the pressure will be unequally distributed wherever the line of the equilibrated polygon does not cut the centre of the

joint. Greater or less elastic resistance in the stone corresponds to greater or less curvature in the surface of the joint. A small distortion of the arch will restore equilibrium when the curvature is great, or when the stone has a high modulus of elasticity. The ring with plane bed-joints is in stable equilibrium, and adapts itself to new distributions of load for precisely the same reasons as the model with curved joints, but in the one case the couple called into play to move the voussoir is actually cancelled by the new position which the points of contact assume; in the other case it is balanced by the equal and opposite couple resulting from the resistance to motion due to the hardness of the stone.

The preceding paragraph showed how to determine whether an arch was in equilibrium when a known reaction was applied at one abutment; the experiment and reasoning now given show that the incipient yielding of an arch under loads will produce a reaction at the abutments suited to keep the whole ring in equilibrium, provided only an equilibrated polygon can be drawn, cutting the joints within the ring at suitable angles.

§ 41. *Practical Investigation of the Stability of a given Arch under a given Load—Joint of Rupture.*—This investigation resolves itself into finding that equilibrated polygon or linear arch which can be drawn within the (middle third of the) ring from the crown to the *lowest possible joint* of the ring (or to the springing if this be possible). This lowest possible joint must in any case be treated as the springing of the arch, and if the linear arch goes out of the (middle third of the) ring above the actual springing, as will be the case in all semicircular or elliptical rings, masonry must be provided in the backing capable of taking the actual thrust into the abutment and constituting the real arch, which often differs widely from the form indicated by the ring of stones in the face. The linear arch in a circular or segmental bridge loaded simply by its own weight generally has a smaller radius of curvature than the ring at the crown, and a much larger radius towards the haunches. Consequently, the longest linear arch which can be drawn within the ring will approach the upper surface of the ring at the crown and the soffit towards the haunches.

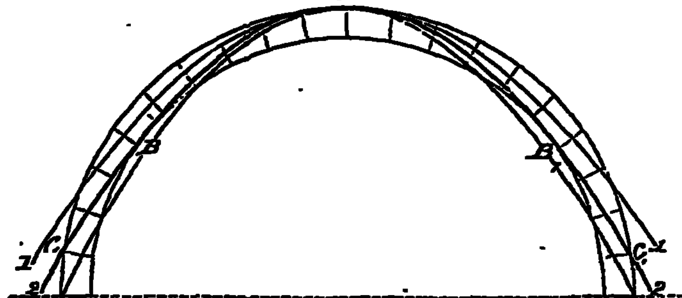

Fig. 49.

Fig. 49 shows a series of linear arches, all drawn for the same load, and all tangent to the upper surface of the crown of the arch, differing only in being the result of different horizontal thrusts. The curve drawn with a thick black line, tangent to the soffit, is clearly the longest linear arch which can be drawn within the ring. Any smaller value of the horizontal thrust h would give a linear arch like curve 3, and any larger value of h would give a linear arch like curve 1, and both these values of h are incompatible with equilibrium for the whole arch down to joint C; if, therefore, the arch fails by the yielding of the abutment, or of the lower portion of the ring, the failure will first be apparent at the joints A and B, where this black line is tangent to the ring, and at joint C, where the linear arch cuts the back of the ring. Smaller values of h will keep the stones in equilibrium above and below joint B, but unless the arch below the joint B, as well as the abutment, can resist the tendency of the arch to spread, or, in other words, supply *at least* the horizontal reaction h required for this linear arch, the joint B will open at the top, the centre joint A will open at the bottom, the joint C will open at the back, and the crown fall in as shown in fig. 49*a*. The joint B, where the longest linear arch is tangent to the soffit, is called the *joint of rupture*. The value of h required to make a linear arch tangent to the back of the ring at the crown pass through the edge of the joint of rupture at the soffit, is larger than the value of h required to give a linear arch passing through the edge of any other joint at the soffit; at the same time, it is the smallest value of h consistently with which the arch can remain in

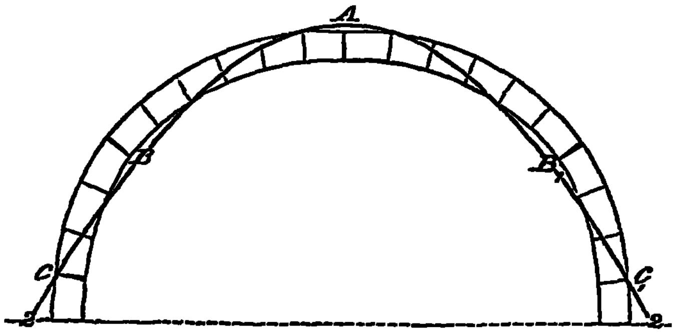

Fig. 49*a*.

equilibrium down to B and from B to C. In circular arches the joint of rupture generally makes an angle of about 30° with the horizontal plane; in elliptical arches the angle is usually about 45°. Its position is easily found as follows:—Let y_1, y_2, y_3, &c. (fig. 50), be the heights of the upper surface of the crown A above any points

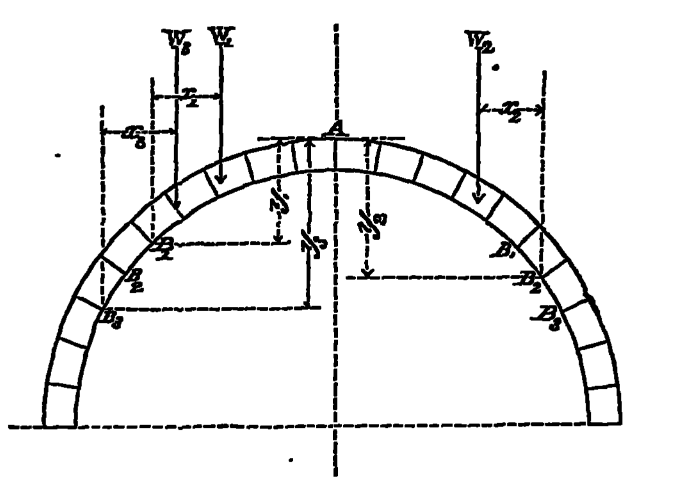

Fig. 50.

B_1, B_2, B_3 at the lower edges of the soffit; let W_1, W_2, W_3 be the weights of the portions of the arch with its load carried by the ring from B_1 to A, from B_2 to A, from B_3 to A, &c. (The load is in the fig. assumed to be symmetrically disposed relatively to the centre of the span.) Let x_1, x_2, x_3 be the horizontal distances of the centres of gravity of w_1, w_2, w_3 from the points B_1, B_2, B_3, &c.; then taking moments round B_1, B_2, B_3 in succession, we have, if the linear arch be assumed to pass through any point B—

$$Wx = hy;$$

taking the successive values of h for a series of joints B, we shall find that one joint gives a maximum value. This value corresponds with that of the linear arch tangent to the soffit (of the middle third) at the joint of rupture; for this arch has the maximum thrust *of any passing through the points B_1, B_2, &c., as appears by simple* inspection of fig. 49. The joint of rupture can thus be tentatively found, and the value of h, or the thrust which the abutment must resist, is obtained at the same time. If the backing is carried well up above C, a larger value of h than that obtained by this method would be consistent with the stability of the arch, and might actually occur; but we need not provide for this larger value, since the yielding of the abutment under it would diminish the thrust till it fell to the value as above determined. If the abutments could resist this thrust, the bridge would then remain in equilibrium. If the arch is flat there may be no joint of rupture, and in that case the value of h is to be taken as that given by a linear arch passing through the bottom of the (middle third of the) springing and tangent to the crown of the arch, *i.e.*, to the summit of the middle third of the ring.

When the apparent springing lies much below the joint of rupture, we find that the linear arch leaves the ring on the upper surface at a joint (C) lower down, where failure must result by the opening of the joint at the lower surface, unless the pressure is taken by masonry outside the ring. It is for this purpose that the *backing* is required. Obviously the best mode of supplying backing is to thicken

the ring itself, keeping the masonry joints radial. The portion of the arch below the joint of rupture B is often considered as part of the abutment.

If the load at the crown of an arch were very light, and the load at the haunches comparatively very heavy, the series of tentative curves drawn with various values of h would assume the character shown in fig. 51. The longest curve which can now be fitted into the ring (drawn with a thick black line in the figure) will probably approach the soffit at the crown and be tangent to the upper surface of the ring at the haunch. In fig. 51 the longest linear arch is shown as tangent to the soffit at C. This condition could seldom be secured; with most loads the linear arch tangent to the back of the ring at B will *cut* the soffit at C. Nevertheless, the value of h to be provided for will be that given by the linear arch tangent to the soffit. If *this arch leaves the middle third* at B, the ring must be thickened or efficient backing provided at this point. If the abutment yield an arch thus loaded would *fail*, as in *fig. 51a*, but the case very seldom arises in practice. If the arch were not pointed at A, but curved so as to contain the linear arch near the crown, the piece BAB would be lifted up as a whole without breaking at A.

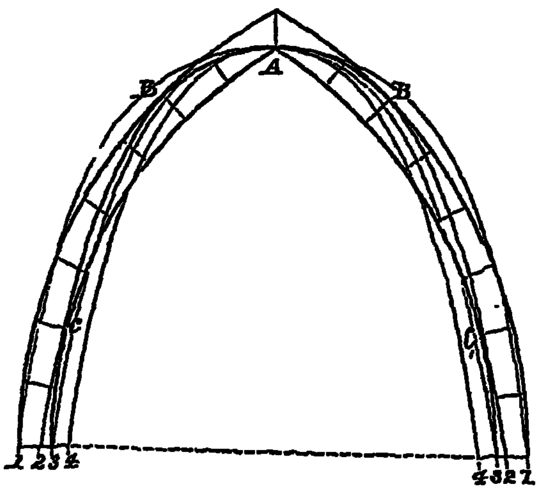

Fig. 51.

The joints of rupture can be found for unsymmetrical loads as well as for symmetrical loads, but these joints will then not be at equal distances from the crown.

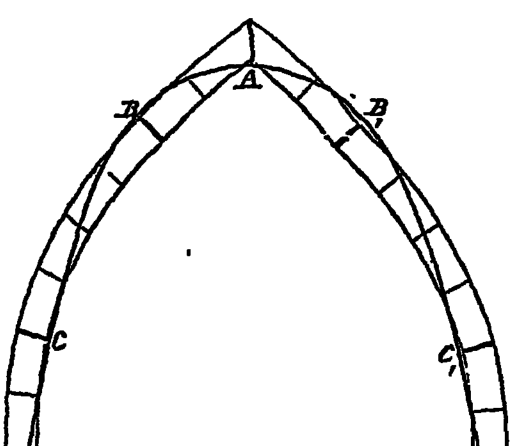

Fig. 51a.

If the middle third of the ring be alone treated as effective, the designer, after finding the joint of rupture for a bridge of the usual form and with usual loads, need make no further calculation as to the arch *above* that joint. A linear arch which is tangent to the soffit at the joint of rupture, and to the upper surface of the ring at the crown, will probably lie within the ring at intermediate joints, and will cut them at an angle not differing much from a right angle; but the linear arch must be carried on below the joint of rupture, through the backing and the abutments, to see that it is nowhere too much inclined to the bedding joints, and never comes too near the edge of the effective masonry. The horizontal thrust determined by finding the joint of rupture on the hypothesis that the middle third of the ring is the only effective part will be a safe value; but the actual value may be considerably less, since the actual linear arch called into play may lie outside the middle third. Since we do not know the actual position of the resultant pressures on each voussoir, any refinement in calculating the maximum intensity of stress due to these resultants would be useless. If the actual horizontal thrust were known, it would be easy to determine the couple acting on each joint and due to the distance between the resultant pressure and the centre of resistance of the joints; then knowing this couple and the total thrust it would be equally easy by the principles in § 8 to determine the maximum intensity of stress. Practically the thickness of the arch ring is determined by rules derived from experience, and the chief use of the above theory is to determine the dimensions of the abutments; if, however, with a given load the joint of rupture were found much nearer the crown than the positions indicated above, it would be well to rearrange the permanent loads or to alter the form of the ring.

§ 42. Professor George Fuller of Belfast has communicated the following novel and very neat method of finding the linear arch of maximum rise (and therefore of minimum thrust) which can be drawn within the middle third of a given ring.

In fig. 52 let the dotted curves GI and HK bound the middle third of the ring. Let the span be divided into any convenient

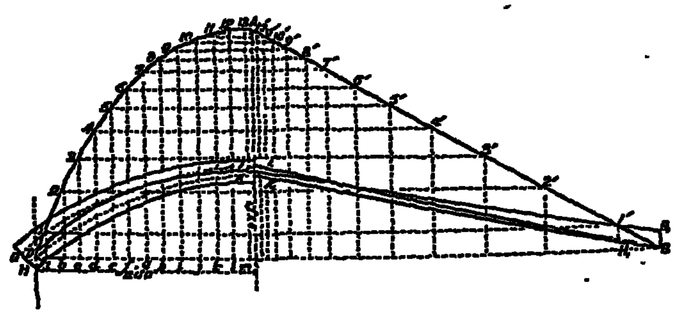

Fig. 52.

number of parts at a, b, c . . . &c. Let the load on the half arch be subdivided into a corresponding number of parts, and each partial load referred to the vertical line passing through a, b, c . . . &c. Let the curve D 1 2 3 . . . A be a curve of bending moments for these loads, drawn to any convenient scale. This curve will also (§ 30) be a linear arch for the given loads. Draw the straight line AB at any convenient inclination, cutting the horizontal line DB at B. Raise the verticals a1, b2, c3, . . . &c., from the points 1, 2, 3, &c. Where these cut the curve DA draw horizontal lines, cutting AB at 1′, 2′, 3′, . . . &c. Since the ordinates of all possible linear arches are merely multiples or submultiples of the curve of bending moments, it follows that any other straight line from B to the vertical through A will have ordinates, which, if measured from DB along the verticals passing through 1′, 2′, 3′, &c., will be the ordinates of a linear arch, set off on the corresponding verticals passing through 1 and a, 2 and b, 3 and c, &c. AB might be called the development of the linear arch DA. Now let the curves CI and HK be developed in a similar way, so that, for instance, the ordinates measured from a to these curves are equal to the ordinates measured on the vertical passing through 1′ from DB to the developments $I_1 G_1$ and $H_1 K_1$; then it is clear that for the given loads any linear arch which lies within the middle third of the ring must, when developed, be represented by a straight line lying within the area $I_1 G_1 H_1 K_1$, and consequently that the straight line BC, which starts from the lowest point B in this area, and is tangent to the curve $G_1 I_1$, will be the development of the curve of

maximum rise and minimum thrust which can be drawn within the given middle third with the given loads. The line BC determines the point C, and the ordinates of BC give the ordinates of the curve DC, the ordinates being measured on corresponding verticals.

The example shown is the diagram for an arch of 52 feet span and 10 feet 4 inches rise, the depth of the ring at the crown being 2 feet 6 inches, and at the springing 3 feet 8 inches. The loads per foot of breadth, beginning at a, are—23·04, 19·45, 16·35, 13·94, 12·01, 10·35, 8·98, 7·93, 6·32, 5·79, 5·52, 5·39 cwts. The rise of the linear arch found is 10·2 feet, and h per foot of breadth of the arch 129 cwt. $= \frac{1315 \text{ ft. cwt.}}{10 \cdot 2 \text{ ft.}}$

§ 43. *Empirical Expression for the Thickness of the Ring.*—The ring when not of equal thickness is always made of least depth at the crown. The depth of the key stone is therefore the thickness of the ring at its smallest part.

Let D be this depth in feet, and r the radius of the arch in feet at the crown. Then we may take (Trautwine)—

1. . . . . $D = C\sqrt{r}$.

According to Rankine, C may be taken as ·346 for a single arch, and ·413 for one of a series of arches. The reason for making one of a series thicker than a single arch is, that the former has, when not loaded itself, to bear part of the thrust from its neighbours when these are loaded; this thrust tends to throw the linear arch in the unloaded span low down in the keystone. The following is another series of values of C in practical use:—

For first class stonework ....C = ·36
,, second class stonework.................. ......C = ·4
,, brick and rubble......................... ....C = ·45

Perronet gives the following rule:—Let L be the span in feet—

2. . . . . $D = 1 + \frac{L}{30}$.

Rankine, *Civil Engineering*, p. 427, shows that Trautwine's rule is rational. Perronet's can only be so when the usual proportion of rise to span is adopted.

Brickwork arches of 24 feet span and less are made 1 foot 6 inches deep at the crown; 30 feet span, 1 foot 10½ inches; 40 feet span, 2 feet 3 inches. The usual flat arch of these dimensions has its ring increased by two rings of bricks towards the haunches. These do not show on the face being concealed by the spandrils. Rubble arches are made a little thicker.

§ 44. *Practical Details.*—The strongest and simplest form of arch is a flat circular arc, having a rise of about one quarter of the span. In these arches the springing is above the place where the joint of rupture would occur if the ring were prolonged. Those parts of an elliptical or semicircular arch which lie below the joint C, fig. 49, are of use chiefly to improve the appearance of the arch. They are virtually part of the abutment, which is sometimes even considered as extending to the joint B. In a very flat arch the linear arch may be brought to coincide more truly with the axis of the ring by lightening the haunch, with which object the roadway is sometimes carried on small flat arches turned at right angles to the main arch, and having the spandrils of the main arch as abutments.

The joints between the voussoirs should be very evenly worked, so that the pressure may be evenly distributed. In brick joints the layers of mortar should be thin. Great care should be taken to provide for the drainage of the roadway above the arch. With this object the masonry should be covered with a sheet of asphalt sloping down to the piers or abutments, and suitable drains must be provided to collect the water and discharge it through the pier or abutment.

SKEW ARCHES have already been treated of under the general head ARCH (vol. ii. p. 330).

Considerable attention must be given to the construction of the *centres* or wooden frames on which the voussoirs rest while the ring is in process of being built. Extreme rigidity is necessary, and this rigidity is best attained by adopting one of the three following plans (Rankine):—1. Direct supports as in fig. 53, illustrating Hartley's centre for the bridge over the Dee at Chester (total span 200 feet); 2. Inclined struts in pairs as shown in fig. 54, being a diagram of the centre used in the erection of Waterloo Bridge; 3. Trussed wooden girders, of which an example is afforded by the truss used in the erection of London Bridge, fig. 55.

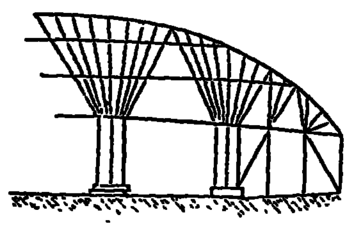

Fig. 53.

Figure 55 shows the *striking plates* and *wedges* by which the centre is lowered after the completion of the arch. The upper and lower plates A and B are strong

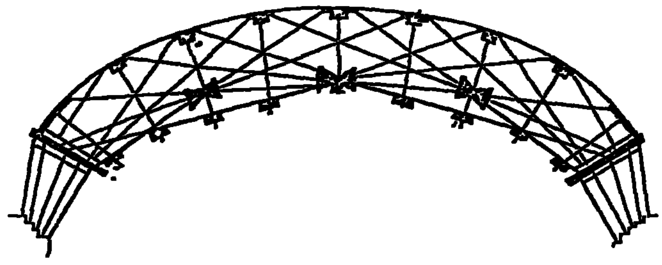

Fig. 54.

beams suitably notched, and are separated by the compound wedge C; this wedge is kept in its place by cross wedges shown in section in the figure. When the centre

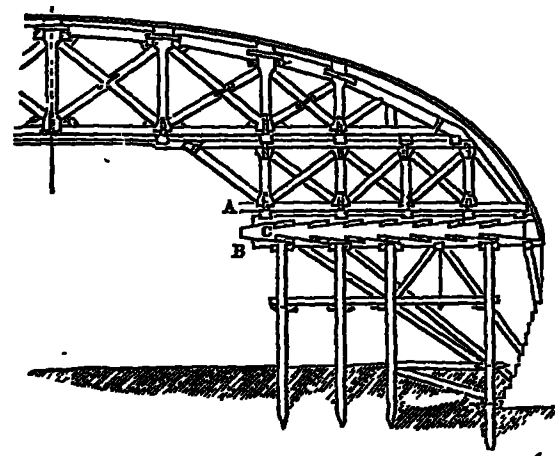

Fig. 55.

is to be lowered these cross wedges are knocked out, and the main wedge C driven back. Owing to defective centering some large French arches sank much during construction, and owing partly to this cause, and partly, as it would appear, to defective mason-work, the total deformation after the centres had been struck was most extraordinary. In Perronet's bridge at Neuilly (*vide* Table XVII., § 84) the sinking, while the centre was in its place, amounted to 13 inches, and after the centre was struck a further sinking took place of 9½ inches. The crown of the centering had a radius of 150 feet, but the sinking of the arch was such that for 60 feet it assumed the form of an arc of a circle with a radius of 244 feet. It is remarkable that the bridge, built in 1774, of very bold design and so imperfectly executed, still stands. When the centres of Waterloo Bridge were removed no arch sank more than 1½ inches. Centres have occasionally been supported on strong sacks full of sand. To lower the centre the sand was allowed to escape through apertures in the sack. It is believed that this method was first employed by a French engineer, M. Beaudemoulin. The canvas sack has been advantageously replaced by wrought iron

boxes or troughs; the block supporting the centre acts as a lid resting on the sand inside; when the sand is allowed to escape the block sinks slowly down inside the box.

§ 45. *Comparison of Metal with Masonry Arches.*—Metal arched ribs may be used instead of rings of masonry to support a platform and roadway. These arched ribs constitute true arches whenever, as is generally the case, all parts of the rib are compressed. The principles by which the stress on each part may be computed do not differ from those already explained for arches of masonry, but it is possible to calculate the stresses with much greater exactitude for continuous metal ribs than for voussoirs. With voussoirs we have seen that the resultant thrust at the springing is indeterminate both in magnitude and position, but we shall see hereafter that the resultant thrust, which will be called t, at the springing of a metal arch is easily rendered determinate. Supposing t and t_1, the thrusts due to a given load (fig. 56), to be known, then if the form of rib be made to

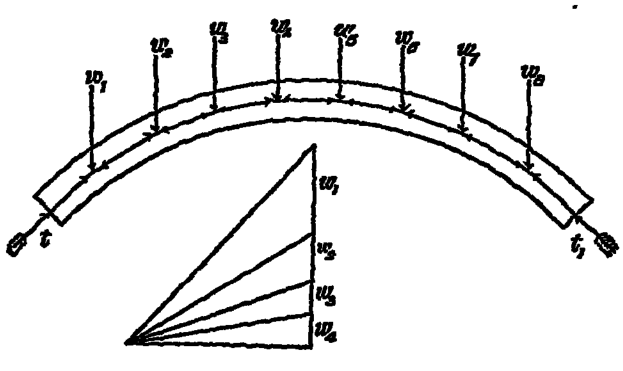

Fig. 56.

correspond with any linear arch for the given distribution the compression at any section of the rib will be axial and uniformly distributed; the arch will then be strained as a chain of the same length would be strained under the same distribution of loads, extension being substituted for compression and dip for rise. Fig. 56 shows a rib of this kind with the approximate linear arch drawn as an equilibrated polygon by the method explained in § 38.

If the distribution of the load is altered the linear arch will also change, and the stress on each part of the rib will no longer be axial. The change in the form of the linear arch will generally be much greater for a metal than for a masonry arch, because most metal arches have light open spandrils and a light roadway, so that the passing load is considerable in comparison with the permanent load. Not improbably the linear arch, when only one haunch of a metal rib is loaded, may pass quite outside the rib for a portion of its length if this rib is made, as is usually the case, of a form containing the linear arch for a symmetrically distributed load. On the other hand, it does not follow, as with masonry, that because the linear arch passes outside the rib the bridge will fail. The bending couple then produced can be resisted by the moment of the elastic forces of the cross section of the rib if the rib is made strong enough. In masonry the joints open so soon as the resultant pressure passes outside the middle third of the ring; the couple required to produce equilibrium would then require a negative force or tension at the opposite edge, and masonry cannot supply this tension, but in a metal rib the couple or bending moment produced by the excentricity of the stress may be resisted by the stiffness of the rib acting as a beam subject to a bending moment. Thus the strength of an arch to resist flexure is a more important element in the metal rib than in the masonry structure. It would be false to say that the ring of voussoirs had *no strength* to resist flexure, for we have on the contrary seen that the moment of the elastic forces at any section of a stone ring does resist any distorting action produced by the load; but in masonry this moment should never exceed the comparatively small value consistent with the absence of tension on any part of any joint. The metal rib may with safety be subjected to considerable tension in parts, and its strength to resist flexure can be easily increased and can be calculated with certainty. Moreover, by hinging the rib at one or both springings, as can be done with metal, the problem of determining the horizontal thrust (or total thrust) is simplified, the position of the thrust being thereby rendered certainly axial at this point, and then by taking into account the actual deformation of each part of the rib a complete solution of the problem of its strength can be obtained.

§ 46. *Horizontal Thrust of a Metal Arch or Rib hinged at the Abutments.*—By supporting a rib on pins or in cylindrical bearings (*vide* fig. 62) at the abutments we determine two points traversed by the thrust. The effect of allowing free rotation is necessarily to render the bending moment *nil* round the centre of rotation. Hence the resultant thrust must traverse the centre of the pin, or the centre of curvature of the bearing. Knowing the point of application of the thrust we have now to determine its magnitude. The vertical component v is the same as the load on the pier of a girder of the same span equally and similarly loaded, so that the problem reduces itself to the determination of h the horizontal component.

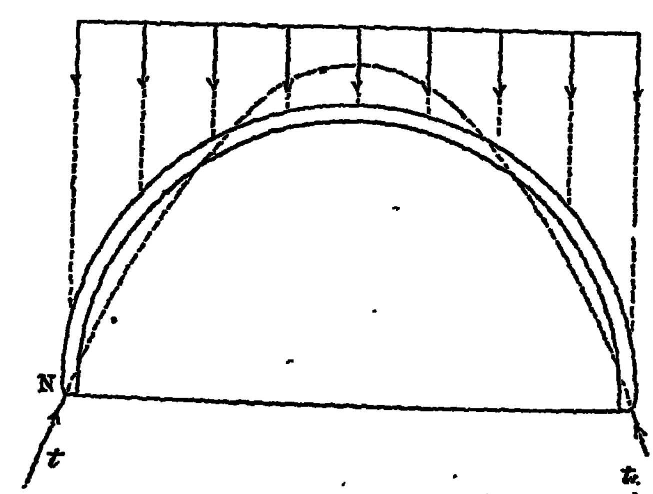

Fig. 57.

Let us first consider a semicircular rib (fig. 57), bearing a load uniformly distributed along the horizontal platform of the bridge (neglecting the weight of the rib). The linear arch will pass through the centre of the bearings N and Q, and will be a parabola. Moreover, it will be that parabola which requires the rib to exert no internal forces due to its own elasticity, and tending either to push out or draw in the springings; in other words, the rib, being supposed in equilibrium before the application of the weights, will not tend to act as a spring to increase or diminish the opening between N and Q. Nevertheless, as the semicircle cannot coincide with the parabola, most parts of the rib must be subject to bending moments, against which it will react as a bent spring. When the linear arch, as shown in fig. 57, passes above the axis of the rib at the crown, and below it at the haunches, the upper portion of the bent rib will act as a spring, tending by its reaction to diminish the distance between the ends N and Q, while the portions near the springing will be so bent as by their reaction to tend to increase that distance; now, if, as is necessarily the case, the whole rib is not to act as a spring, tending either to close or open the ends N and Q, then the effect of the bending near the haunches must exactly neutralize the effect of the bending near the crown. We have now to find what direction of thrust at the springing will give a linear arch such that the above condition may be fulfilled.

Let M be the bending moment acting at any given section, the centre or neutral axis of which is at a height y (fig. 58) above the horizontal line joining the springings; let this moment be considered constant for a short length ΔL of the rib measured axially along the rib; let Δs be the short distance measured horizontally by which the moment M acting throughout the length ΔL would

increase or diminish the span of the rib at the springings, the rest of the rib being assumed free from strain. Then calling I the moment of inertia of the cross section of the rib, and E the modulus of elasticity, we shall have—

1. . . . . . . $\Delta s = \frac{My.\Delta L}{IE}$,

as appears from the following considerations:—

In fig. 58, let $Oo = Aa = Bb = \Delta L$; conceive the surface at AB as fixed, and let the action of the couple M be such as to extend the

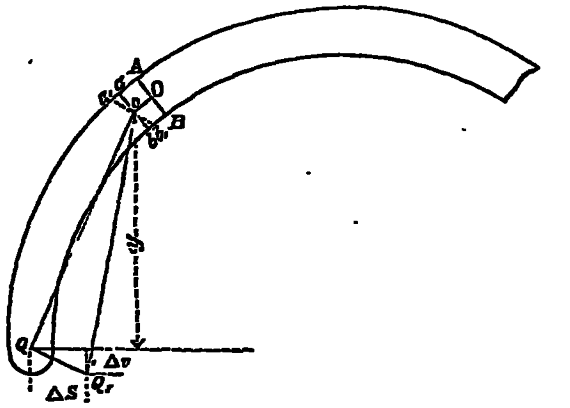

Fig. 58.

top and compress the bottom of the rib, moving the point a to a_1, and the points b to b_1; then, calling p the intensity of the stress at a, we have (equation 4, § 14)—

$$M = \frac{2p_1 I}{d};$$

also we have (§ 24)—

$$aa_1 = \frac{p_1 \Delta L}{E};$$

and therefore—

$$aa_1 = \frac{M\Delta L}{EI}\frac{d}{2};$$

join o and Q and draw the line oQ_1, making the angle QoQ_1 equal to aoa_1; at Q draw $\overline{QQ_1}$ perpendicular to $\overline{oQ}$. Then the effect of the couple M on the length ΔL of the rib, the rest being unstrained, will be to move the point Q to Q_1, and by similar triangles we have—

$$\overline{aa_1} : \overline{QQ_1} = \frac{d}{2} : \overline{oQ};$$

and therefore—

$$\overline{QQ_1} = \frac{M.\Delta L}{E.I}.\overline{oQ}.$$

Then resolving the motion $\overline{QQ_1}$ into horizontal and vertical components Δs and Δv, we have by similar triangles, $\Delta s : QQ_1 = y : oQ$, or, as above—

$$\Delta s = \frac{My.\Delta L}{I.E}.$$

But if, as above stated, the rib does not act as a spring in either direction, the span will remain constant, and the sum of all the changes in span produced by all the successive lengths ΔL will be *nil*, or $\Sigma \Delta s = 0$. Hence, since E is constant, we have

2. . . . . . . $\Sigma \frac{My.\Delta L}{I} = 0$

as a necessary condition for the equilibrium of a loaded rib, hinged at the abutments when these do not yield. This condition must be satisfied whatever be the form or load of the rib, the reasoning by which it was obtained being independent of the form either of the rib or linear arch. When the cross section of the rib is constant, we have—

3. . . . . . . $\Sigma My.\Delta L = 0$.

We shall now proceed to show how the linear arch satisfying this condition can be found for the case of a uniform rib.

Let the line $OO_1O_2O_3O_4$, fig. 59, be the geometrical axis of the rib, and let $OC_1C_2C_3C_4$ be the linear arch required; this arch will, as shown above, cut the geometrical axis at some point, as at O_3.

Let $\overline{C_4C}$ represent the resultant pressure on the rib at any point C_4 in direction and magnitude, fig. 60. If this pressure be resolved into its vertical and horizontal components, the latter $\overline{C_4H}$ will be equal to the horizontal thrust h (constant throughout the linear arch since the loads are vertical).

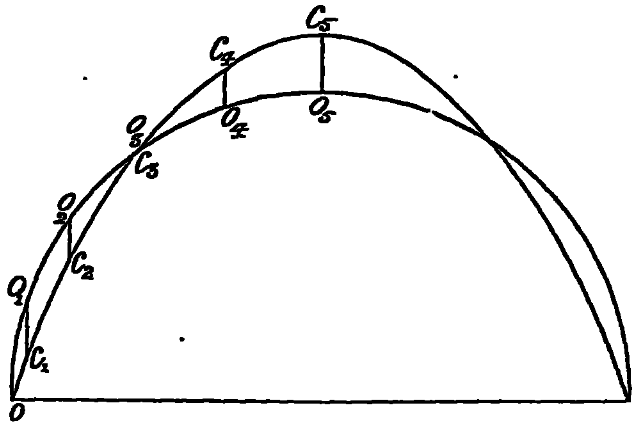

Fig. 59.

This force applied at C_4 will be equivalent to an equal and parallel force, $O_4H_{,,}$, applied at the point, O_4 in the axis, added to a left handed couple, of which the moment is $h\ \overline{O_4C_4}$. This couple

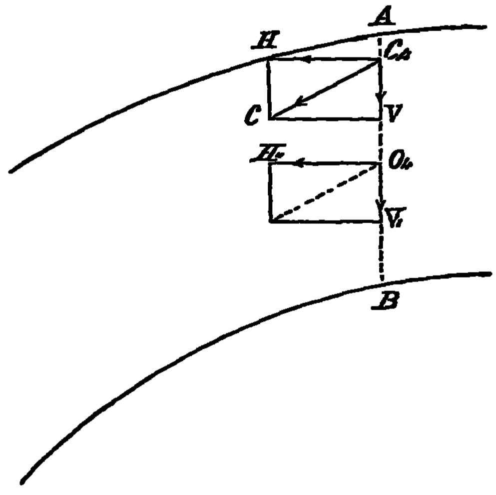

Fig. 60.

is, for the point O_4, the couple M* required for equations 1, 2, and 3, the magnitude of which, h being constant, is proportional to the vertical distance OC between the curves at any point. Equation 3 requires that the sum of all the values of My shall be equal to zero, and we now see that this condition results when the sum of all the products of OC into y is equal to zero, or when—

4. . . . . $\Sigma y.OC = 0$;

when the cross section is not constant the value of $\frac{y.OC}{I}$ must be substituted for the simple product $y.OC$.

The problem of discovering the actual linear arch which will be called into play with a given rib is now reduced to that of finding the linear arch fulfilling the condition in equation 4. We might proceed tentatively, drawing numerous linear arches, and selecting by trial that which most nearly fulfils the condition, as proposed by Mr Bell, *Proc. I.C.E.*, vol. xxxii., but Professor Fuller of Belfast has shown, *Proc. I.C.E.*, vol. xl., that the ordinates of the required linear arch can at once be calculated from the values of the bending moment at the several sections of a beam of equal span and similarly loaded. Let $og_1g_2g_3$ (fig. 61), be the curve of bending moments which, as was shown in § 30, is one form of linear arch corresponding to the given load, the lengths $\overline{oo_1}$, $\overline{o_1o_2}$, $\overline{o_2o_3}$ &c., being equal and representing ΔL; let y as before be any ordinate of the curve $oo_1o_2o_3$, the axis of the rib; let $\overline{sg}$ be any ordinate of the given curve of bending moments; let $\overline{sc}$ be any ordinate of the required linear arch. Then, since $\overline{oc} = \overline{sc} - y$, we have for the case of uniform cross section and hinged abutments the equation—

5. . . . . $\Sigma y(\overline{sc} - y) = 0$, or $\Sigma y.\overline{sc} = \Sigma y^2$;

* This couple is sufficient to shift the force from C_4 to O_4, but the resultant of the force at C_4 and the couple would not be tangent to the geometrical axis of the rib. To alter the direction of the force in this manner a vertical component must be added, but this vertical component may be looked upon as a shearing force, which, being vertical, tends neither to extend nor to diminish the span.

but the ratio $\overline{sc} : \overline{sg}$ is constant, and may be designated by the letter k; so that we may write $k\,(\Sigma y.\,\overline{sg}) = \Sigma y^2$, from which equation we find the value of k—

$$6. \quad \ldots\ldots\ldots \quad k = \frac{\Sigma y^2}{\Sigma y.\,\overline{sg}}.$$

If the cross section is not constant we have for k the more complex expression—

$$7. \quad \ldots\ldots\ldots \quad k = \frac{\Sigma \frac{y^2}{I}}{\Sigma \frac{y.\,\overline{sg}}{I}};$$

but $\overline{sc} = k.\overline{sg}$, so that the required ordinate sc is at once obtained in terms of k and the known ordinate $\overline{sg}$.

When the actual linear arch $oc_1c_2c_3$, &c., has been thus obtained, it is easy to calculate the horizontal thrust; for let $\overline{s_5c_5}$ be the maximum ordinate, the direction of the thrust will at this point of the curve be horizontal, and therefore calling W the weight on one side of this ordinate, and x the distance of its centre of gravity from the springing, we have—

$$8. \quad \ldots\ldots\ldots \quad Wx = h.\overline{s_5c_5},$$

from which h can be found.

h and v being known give the position and direction of the resultant thrust at the springing of the rib. The magnitude of the thrust at any other point is easily computed graphically or by moments

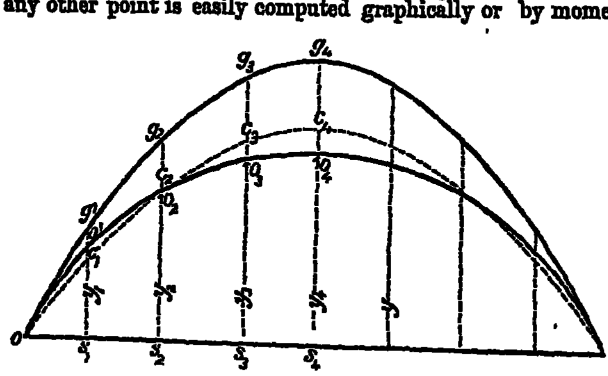

Fig. 61.

round the springing; then the resultant thrust at a given point being known, the intensity of the stress on any part of a section at that point is to be computed by first resolving the thrust into two components, one normal to the section and one in the plane of the section; the latter gives rise to a shearing stress (analogous to the force which causes one stone to slip on another in the masonry arch), while the component normal to the section will (if not axial) give rise to a uniformly varying stress, the magnitude of which at each distance from the axis can be computed by the formulæ given in § 8.

The value of h is determinate, if the direction of the rib be supposed fixed at the springing, but this cannot be ensured in large structures, and the theory need not therefore be developed. It simply requires $\Sigma\, co = 0$.

When the rib (as is generally the case in existing bridges) abuts against a flat springing the exact value of h is indeterminate. When the rib is hinged the friction at the bearing renders the thrust indeterminate within limits depending on the possible bending moment at the springing due to the friction.

§ 47. *Process of Designing a Rib.*—In future designs of ribbed arches it is to be hoped that the practice will be adopted of allowing the rib freedom to turn at the springing. This can be done by ending the rib in a bearing, curved as in fig. 62; the resultant thrust will then be approximately axial, and the stress on every part of the rib can be determined with as much accuracy as on the several parts of a girder. When the span is large a cast-iron metal arch can be made lighter than a wrought iron girder for the same load, but the imperfection of the theory of the stresses on the ribs has hitherto led to great waste of metal in their construction. In what follows it is assumed that the resultant at the springing passes through the geometrical centre of the cross section of the rib.

If the rib were to carry a load distributed only in one way we ought clearly to make the form of the axis of the rib coincide with a linear arch for that load. There would then be no bending moment on any part of the rib. As in practice we must provide for all the possible combinations of passing load, we need take little pains in designing the curvature of the rib—a flat arc of a circle with a rise of say $\frac{1}{8}$th will answer well. The semicircular or elliptical forms are not good, for no linear arch with any practical distribution of load can even approximately coincide with a form in which the rib springs vertically from the abutments.

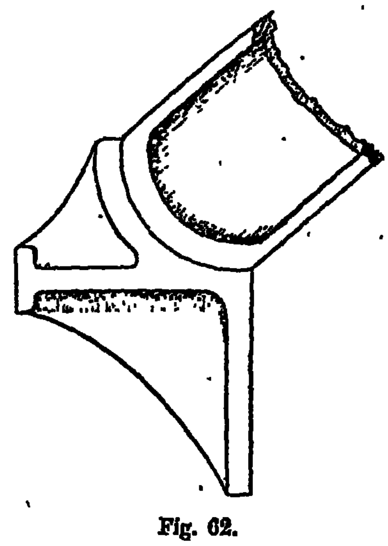

Fig. 62.

The general character of the cross section should be similar to that for a girder, inasmuch as the rib will have to resist bending moments as well as direct compression. The depth need not, however, be nearly so great as the depth of a girder. Let a cross section be chosen in which the area is assumed as approximately say 5 per cent. more than that which would be sufficient to sustain the thrust resulting from a linear arch suitable for the maximum load and coinciding approximately with the axis of the rib. (If the load be nearly uniform per foot run of platform we may for this first approximation take $h = \frac{wl^2}{8d}$, where d is the rise of the linear arch above the springings.) With the rib thus designed determine by the method given in § 46 the actual linear arches resulting from the following arrangements of passing load (combined with the permanent load):—(1), Bridge half covered from one end; (2), three-quarters covered from one end; (3), wholly covered; (4), covered by the passing load over the middle half of the bridge, the haunches being unloaded. Draw these linear arches on the rib by the method given in § 38, and choosing at each one of some eight or ten selected sections the two curves which most nearly approach the top and bottom flanges respectively, compute the maximum intensity of stress on the top and bottom flanges at each section from the two thrusts corresponding to these two linear arches; where the stress is excessive add metal; remove it where the maximum stress is less than the safe stress for the material. If no great change is made in the design this process will be sufficient, but if the cross section is seriously modified by the alteration we must make a second approximation by recalculating the linear arches for the new form of rib, and thus proceed by trial and error until the stresses corresponding to the actual linear arches are met by sufficient metal at all points. The rib need not be of uniform depth throughout, and may be increased in depth at the places where the stress due to bending moment has been found excessive.

In large spans the effect of a change of temperature must be taken into account. This can be done by finding the linear arch given by the expression—

$$1. \quad \ldots\ldots \quad \Sigma \frac{M\Delta l}{I} y = \Delta s,$$

where Δs is the alteration in span which would result from the expansion or contraction of the span if free to expand or contract with the change of temperature.

In a series of arches abutting against comparatively slender piers, account must be taken of the thrust transmitted from the neighbouring arch. This thrust will only be due to the passing load, and a part may be considered as taken by the pier; the remainder which the

pier cannot counterbalance must be compounded with the reaction due to the linear arch calculated for the permanent load of the unloaded span. With the reaction thus computed the linear arch resulting in the unloaded span must be constructed, and the stresses examined on the top and bottom flanges of the rib.

The theory now given for a stiff rib used as an arch is equally applicable to a stiff rib hung as a suspension bridge.

§ 48. *Wooden Arches.*—Arches have occasionally been built of wood with ribs elaborately constructed of bent timber, scarfed and bolted together; the strength of such a rib could be calculated in the way indicated for metal ribs, but the mode of construction is not to be recommended. When wood is employed it should be used in simple straight balks built into a framed arch.

§ 49. *Practical Details of Metal Arches.*—The common form of metal arch is a cast-iron rib of I section and of small depth. This rib is intended to be sufficient, unaided, to bear the whole weight of the superstructure. The spandrils, made of some kind of lattice work (or occasionally a mere arcade), bear the roadway, and to some extent stiffen the rib beneath. The rib may with advantage be made much deeper than has been the practice, and may consist of tubes framed as in the St Louis Bridge, fig. 5, Plate XVIII., so as to form a single stiff rib. Where, to gain headway, a rib of small depth at the crown is desirable, the rib might with advantage be deepened at the haunches. Wrought iron is a very suitable material for small arches, where the permanent load is insufficient to prevent tension from occurring in some parts of the rib. Cast-iron and cast-steel are better materials for large spans; for moderate spans a good form of metal arch will be shown under the head of "Frames" (fig. 77), being that in which a lower member is braced to the upper member carrying the roadway so as to form a true frame; for very large spans a single deep rib, or a frame with parallel members arranged as an arch, may be adopted. This design has the advantage over that shown in fig. 77 of avoiding very long bracing at the abutments.

V. Frames.

§ 50. *Preliminary.*—A frame is a rigid structure composed of straight struts and ties. The struts and ties are called the members or pieces of the frame. The frame as a whole may be subject to a bending moment, but each bar, pillar, rod, or cord in the structure is thereby simply extended or compressed so that the total stress on a given member is the same at all its cross sections, while the intensity of stress is uniform for all the parts of any one cross section. This result must follow in any frame, the members of which are so connected that the joints offer little or no resistance to change in the relative angular position of the members. Thus if the members are pinned together, the joint consisting of a single circular pin, the centre of which lies in the axis of the piece, it is clear that the direction of the only stress which can be transmitted from pin to pin will coincide with this axis. The axis becomes, therefore, a line of resistance, and in reasoning of the stresses on frames we may treat the frame as consisting of simple straight lines from joint to joint. When the members of a frame consist of iron rods as ties, combined with struts formed by angle iron or T iron of the usual sizes, or by pieces of timber of the ordinary dimensions, it is found by experiment that the stresses on the several members do not differ sensibly whether these members are pinned together with a single pin or rigidly jointed by several bolts or rivets. Frames are much used as girders, and they also give useful designs for suspension and arched bridges. A frame used to support a weight is often called a *truss;* the stresses on the various members of a truss can be computed for any given load with greater accuracy than the intensity of stress on the various parts of a continuous structure such as a tubular girder, or the rib of an arch. Many assumptions are made in treating of the flexure of a continuous structure which are not strictly true; no assumption is made in determining the stresses on a frame, except that the joints are flexible, and that the frame shall be so stiff as not sensibly to alter in form under the load. Both assumptions are consistent with the facts in the case of any bridge truss.

§ 51. *Classes of Frames used as Trusses.*—Frames used as bridge trusses should never be designed so that the elongation or compression of one member can elongate or compress any other member. An example will serve to make the meaning of this limitation clearer. Let a frame consist of the five members AB, BD, DC, CA, CB (fig. 63), jointed at the points A, B, C, and D, and all capable of resisting tension and compression. This frame will be *rigid, i.e.*, it cannot be distorted without causing an alteration in the length of one or more of the members; but if from a change of temperature or any other cause one or all of the members change their length, this will not produce a stress on any member, but will merely cause a change in the form of the frame. Such a frame as this cannot be *self-strained.* A workman, for instance, cannot produce a stress on one member by making some other member of a wrong length. Any error of this kind will merely affect the form of the frame; if, however, another member be introduced between A and D, then if BC be shortened AD will be strained so as to extend it, and the four other members will be compressed; if CB is lengthened AD will thereby be compressed, and the four other members extended; if the workman does not make CB and AD of exactly the right length they and all the members will be permanently strained. These stresses will be unknown quantities, which the designer cannot take into account, and such a combination ought therefore never to be adopted. A frame of this second type is said to have one *redundant member.*

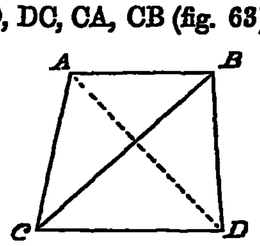

Fig. 63.

If the members AD and CB were flexible cords there would be no redundant members; for the tightening of one diagonal would throw no sensible stress on the other diagonal, since it is supposed incapable of resisting a thrust. Both diagonals, if flexible, are required to prevent the quadrilateral from getting out of shape. Members capable of bearing only one kind of strain might receive the name of *semi-members.*

§ 52. *External Forces on Frame.*—Frames used as bridge trusses are in equilibrium under the external forces applied to them. These forces are—(1) the loads, (2) the reactions at the points of support. The loads are to be referred to the joints as follows:—(1) find the resultant of the load carried by any two joints; (2) resolve that load into two vertical components acting through the two joints; (3) compound the several components acting at each joint into one resultant. This process gives a frame with external forces equivalent to the actual loads, but acting only at the joints. The frames are always supported at a joint, and the reactions of the supports are therefore also forces acting at joints. The load between any two joints is directly supported by the member of the frame joining them; the stresses due to the direct action of this partial load must, where great accuracy is wanted, be added to the stresses computed on the assumption that the loads have been applied directly to the joints. Generally the stresses due to the direct action of the load between two joints may

be neglected except where a member of the frame is employed to carry the roadway.

Fig. 64 shows a common form of bridge truss known as

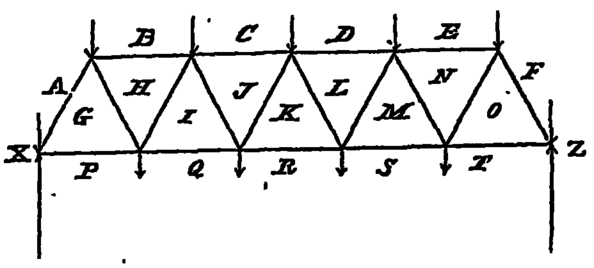

Fig. 64.

a *Warren girder*, with lines indicating external forces applied to the joints; half the load carried between the two lower joints next the piers on either side is directly carried by the abutments. The sum of the two upward vertical reactions must clearly be equal to the sum of the loads. The lines in the diagram represent the directions of a series of forces which must all be in equilibrium; these lines may, for an object to be explained in the next paragraph, be conveniently named by the letters in the spaces which they separate instead of by the method usually employed in geometry. Thus we shall call the first inclined line on the left hand the line AG, the line representing the first force on the top left hand joint AB, the first horizontal member at the top left hand the line BH, &c.; similarly each point requires at least three letters to denote it; the top first left hand joint may be called ABHG, being the point where these four spaces meet. In this method of lettering, every enclosed space must be designated by a letter; all external forces must be represented by lines *outside* the frame, and each space between any two forces must receive a distinctive letter; this method of lettering was first proposed by Mr R. H. Bow (*Economics of Construction*), and is convenient in applying the theory of reciprocal figures to the computation of stresses on frames.

When the weight of the truss is small it is usual to refer the weights of the parts of the truss itself to the same joints as carry the roadway, and to treat all other joints as unloaded.

The reactions at the points of supports of a framed arch or suspension bridge are inclined, as in fig. 65; the manner

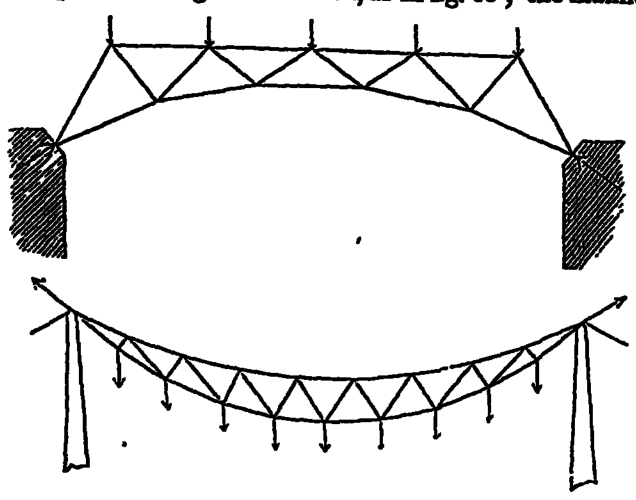

Fig. 65.

of computing the stresses on these frames when the direction of these reactions is known will be first explained, and subsequently the manner of finding this direction will be given.

§ 53. *Reciprocal Figures.*—Prof. Clerk Maxwell has given (*Phil. Mag.* 1864), the following definition of reciprocal figures:—"Two plane figures are reciprocal when they consist of an equal number of lines so that corresponding lines in the two figures are parallel, and corresponding lines which converge to a point in one figure form a closed polygon in the other."

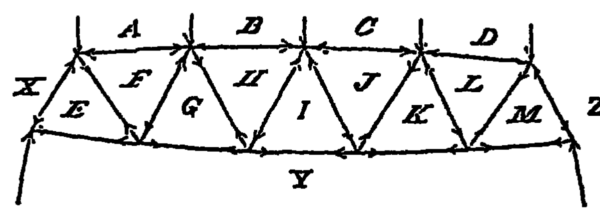
Let a frame (without redundant members), and the external forces which keep it in equilibrium, be represented by a diagram constituting one of these two plane figures, then the lines in the other plane figure or the reciprocal will represent in direction and magnitude the forces between the joints of the frame, and, consequently, the stress on each member as will now be explained.

Reciprocal figures are easily drawn by following definite rules, and afford therefore a simple method of computing the stresses on members of a frame.

The external forces on a frame or bridge in equilibrium under those forces may, by a well-known proposition in statics, be represented by a closed polygon, each side of which is parallel to one force, and represents the force in magnitude as well as in direction. The sides of the polygon may be arranged in any order, provided care is taken so to draw them that in passing round the polygon in one direction this direction may for each side correspond to the direction of the force which it represents.

This polygon of forces may, by a slight extension of the above definition, be called the *reciprocal figure* of the external forces, if the sides are arranged in the same order as that of the joints on which they act, so that if the joints and forces be numbered 1, 2, 3, 4, &c., passing round the outside of the frame in one direction, and returning at last to joint 1, then in the polygon the side representing the force 2 will be next the side representing the force 1, and will be followed by the side representing the force 3, and so forth. This polygon falls under the definition of a reciprocal figure given by Clerk Maxwell, if we consider the frame as a point in equilibrium under the external forces.

Fig. 66.



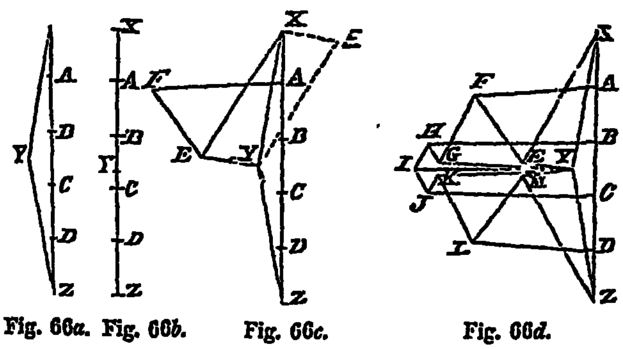


Fig. 66*a*. Fig. 66*b*. Fig. 66*c*. Fig. 66*d*.

Fig. 66 shows a frame supported at the two end joints, and loaded at each top joint. The loads and the supporting forces are indicated by arrows. Fig. 66*a* shows the reciprocal figure or polygon for the external forces on the assumption that the reactions are slightly inclined. The lines in fig. 66*a*, lettered in the usual manner, correspond to the forces indicated by arrows in fig. 66, and lettered according to Mr Bow's method. When all the forces are vertical, as will be the case in girders, the polygon of external forces will be reduced to two straight lines, fig. 66*b*, superimposed and divided so that the length AX represents the load AX, the length AB the load AB, the length YX the reaction YX, and so forth. The line XZ consists of a series of lengths, as XA, AB......DZ, representing the loads taken in their order. In subsequent diagrams the two reaction lines will, for the sake of clearness, be drawn as if slightly inclined to the vertical (as practised by Mr Bow).

If there are no redundant members in the frame, there will be only two members abutting at the point of support, for these two members will be sufficient to balance the reaction, whatever its direction may be; we can therefore draw two triangles, each having as one side the reaction YX, and having the two other sides parallel to these two members; each of these triangles will represent a polygon of forces in equilibrium at the point of support. Of these two triangles, shown in fig. 66*c*, select that in which the letters X and Y are so placed that (naming the apex of the triangle E) the lines XE and YE are the lines parallel to the two members of the

same name in the frame (fig. 66). Then the triangle YXE is the reciprocal figure of the three lines YX, XE, EY in the frame, and represents the three forces in equilibrium at the point YXE of the frame. The direction of YX, being a thrust upwards, shows the direction in which we must go round the triangle YXE to find the direction of the two other forces; doing this we find that the force XE must act down towards the point YXE, and the force EY away from the same point. Putting arrows on the frame diagram to indicate the direction of the forces, we see that the member EY must pull and therefore act as a tie, and that the member XE must push and act as a strut. Passing to the point XEFA we find two known forces, the load XA acting downwards, and a push from the strut XE, which, being in compression, must push at both ends, as indicated by the arrow, fig. 66. The directions and magnitudes of these two forces are already drawn (fig. 66*a*) in a fitting position to represent part of the polygon of forces at *XEFA*; beginning with the upward thrust EX, continuing down XA, and drawing AF parallel to AF in the frame we complete the polygon by drawing EF parallel to EF in the frame. The point F is determined by the intersection of the two lines, one beginning at A, and the other at E. We then have the polygon of forces EXAF, the reciprocal figure of the lines meeting at that point in the frame, and representing the forces at the point EXAF; the direction of the forces on EX and XA being known determines the direction of the forces due to the elastic reaction of the members AF and EF, showing AF to push as a strut, while EF is a tie. We have been guided in the selection of the particular quadrilateral adopted by the rule of arranging the order of the sides so that the same letters indicate corresponding sides in the diagram of the frame and its reciprocal. Continuing the construction of the diagram in the same way, we arrive at fig. 66*d* as the complete reciprocal figure of the frame and forces upon it, and we see that each line in the reciprocal figure measures the stress on the corresponding member in the frame, and that the polygon of forces acting at any point, as IJKY, in the frame is represented by a polygon of the same name in the reciprocal figure. The direction of the force in each member is easily ascertained by proceeding in the manner above described. A single known force in a polygon determines the direction of all the others, as these must all correspond with arrows pointing the same way round the polygon. Let the arrows be placed on the frame round each joint, and so as to indicate the direction of each force on that joint; then when two arrows point to one another on the same piece, that piece is a tie; when they point from one another the piece is a strut. It is hardly necessary to say that the forces exerted by the two ends of any one member must be equal and opposite. This method is universally applicable where there are no redundant members. The reciprocal figure for any loaded frame is a complete formula for the stress on every member of a frame of that particular class with loads on given joints. Some examples of these figures will be given, and the reader will easily construct others for himself.

§ 54. *Warren Girders—Reciprocal Figure and Method of Computing Stresses by Method of Sections.*

Case 1. The Warren girder loaded at each top joint, figs. 67 and 67*a*. This diagram differs very slightly from

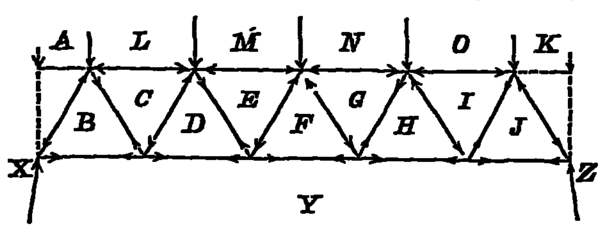

Fig. 67.

that shown in fig. 66. The top and bottom members are in straight lines, and consequently the lines indicating the stresses on the bottom member are superimposed one on the other instead of radiating from Y; the loads XA and FZ are shown as directly borne by the piers. It is clear that if the road is supported by a platform reaching from the end joints to the piers, half of the load on these parts of the platform will be directly supported on the piers. These end loads are shown also in the subsequent diagrams. The truss is generally built of equilateral

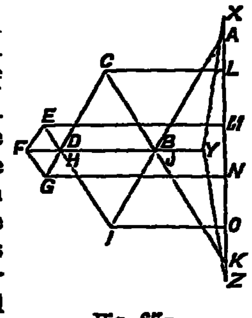

Fig. 67*a*.

triangles, and the inclination of the bracing to the horizon should never be less than 45°.

Case 2. Warren girder loaded on top and bottom, fig. 68. 68*b* shows the polygon of external forces, and 68*c*

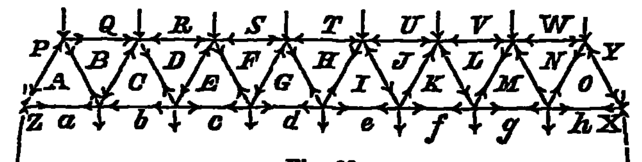

Fig. 68.

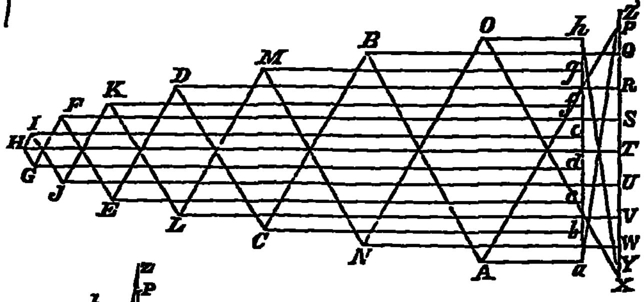

Fig. 68*a*.

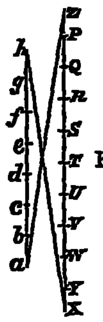

Fig. 68*b*.

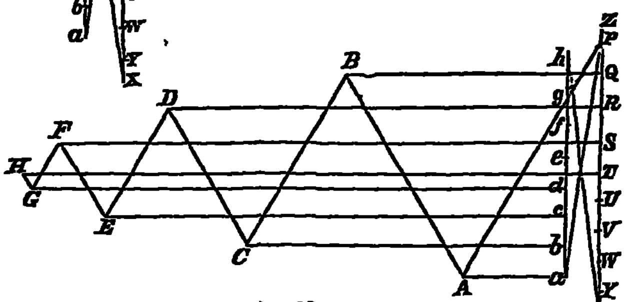

Fig. 68*c*.

shows half the reciprocal figure. These figures have been added to facilitate the comprehension of the complete reciprocal shown by 68*a*

Case 3. Warren girder with one load, not central, fig.

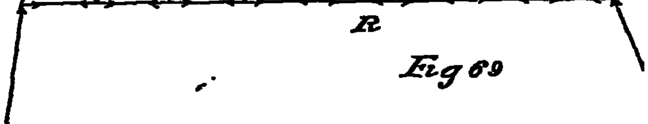

Fig 69

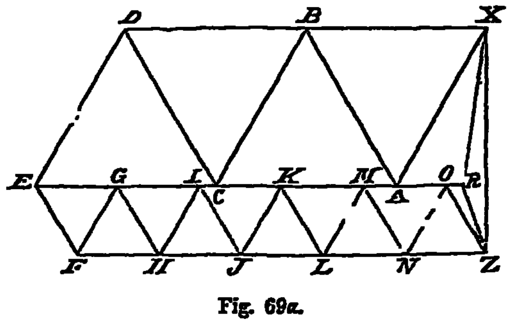

Fig. 69*a*.

69. The polygon RXZ, fig. 69*a*, represents the external forces.

Case 4. Warren girder; *load on half the top joints, fig.* 70.

In designing a Warren girder it is necessary to provide for the advancing load. With a uniformly distributed load the

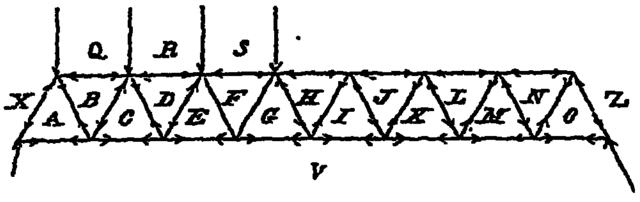

Fig. 70

diagonal bracing consists of alternate struts and *ties* beginning, if supported at the bottom, with a strut at each end, or with the tie at each end if the truss is hung from the top. At the centre there will be either two ties or two struts in juxtaposition; or, as in the case where there are an even number of loaded joints at the top, the central pair of diagonal members

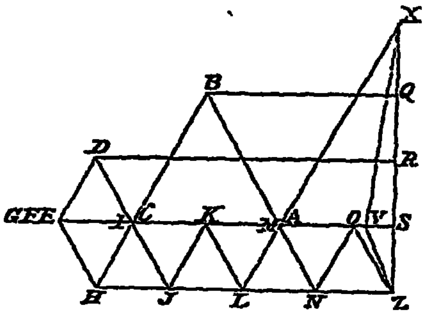

Fig. 70*a*.

will be unstrained; but an advancing load (neglecting the permanent load) will convert each diagonal member (except the end ones) alternately into a *strut* and a *tie*. It is necessary to provide for the maximum extension and maximum compression on each, taking into account the combined effects of the permanent and passing load; the latter has generally sufficient effect to reverse the direction of the stress on the bracing near the centre, but not (in large bridges) towards the ends. Each member of the bracing towards the centre must, therefore, be so designed as to be capable of acting alternately as a strut and as a tie. The maximum stress on the top and bottom members occurs when the bridge is fully loaded.

This stress is easily calculated by the method of sections; assume the girder cut by a vertical plane at the joint or pin opposite the member in question, or in other words, by a vertical plane passing through the vertex of the triangle of which the member in question is the base; let d be the perpendicular distance between the member and the pin, t the thrust or tension on the member, and M the bending moment for the section calculated as for a girder loaded at the points corresponding to the joints. Then $M = td$. The stress on the diagonals corresponds to the shearing stress in the solid girder, and may consequently be calculated from the shearing diagrams, examples of which were given in § 19. The loads may be referred to the joints before drawing the diagram, and the continuous curves of figures 18 to 18*c* will be replaced by lines consisting of a series of steps such as are shown in fig. 18*a*. We may then proceed to calculate the stress on any diagonal as follows:—Take the shearing stress for the section at the joint where the diagonal in question abuts; if there is a load on this joint, take the shearing stress for a section close to the joint, and on that side

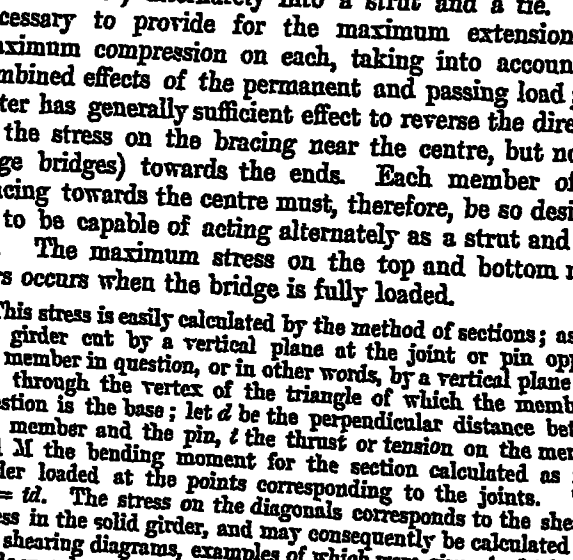

Fig. 71.

of it which is next the diagonal in question; call the shearing force thus found F; let i be the slope of the diagonal or the angle which it makes with the horizon; then the tension or compression on the diagonal is F cosec. i; thus let fig. 71 represent a Warren girder of six equal bays, in which $i = 60°$. Let the load on each top joint be 5 tons, the compressions and tensions on the diagonals are as follows:—

TABLE XI.

Name of Brace.	F × cosec. i.	Compression.	Tension.
1	15×1·1547	17·32	...
2	10×1·1547	...	11·55
3	10×1·1547	11·55	...
4	5×1·1547	...	5·77
5	5×1·1547	5·77	...
6	0×1·1547	...	...

These stresses, given simply as an example, apply to the one special load, and are not to be confounded with *the maximum* stresses which an advancing load of the same intensity would produce. The stresses on the two halves of the girder are symmetrical.

The arithmetical mode of computation is the simpler where the top and bottom members are parallel and the inclination of the diagonals constant; where these conditions are not fulfilled the method by reciprocal figures is preferable.

In the actual design of any girder to suit various combinations of loads, care must be taken to design each member to suit the *maximum* stress which can arise from any combination. The maximum shearing stress is most easily selected by means of the diagrams § 19. Care must be taken to meet both the maximum tension and maximum compression whenever the member is so placed that with some loads it is extended and with some compressed. We have just shown that this case arises in the diagonals near the centre of the girder. When frames are used as continuous girders, it is desirable to make the points of inflection coincide exactly with a joint. This may be done by cutting through or omitting the member opposite the joint. This allows the reactions on each pier to be easily determined by the elementary principles of statics with any load, and without taking into account the form which the beam assumes when deflected. Instead of a long continuous girder, we then have a series of girders, supported at or near the middle of their length by the piers, while a second series hang from the first by pins at determinate points. This arrangement greatly simplifies all the calculations without sensibly diminishing the advantage derived from the use of continuous girders.

§ 55. *Various Forms of Girder.*—The framed girder is sometimes made of the form in fig. 72, which has the

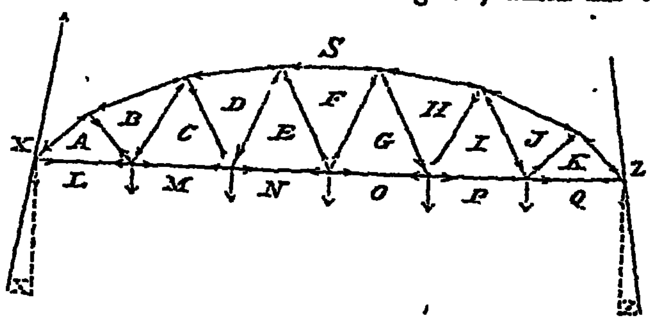

Fig. 72.

advantage of reducing the length of the end diagonals where the stress is heaviest. The reciprocal figure for this truss uniformly loaded on the bottom joints is shown in fig. 72*a*. This girder is sometimes called a bowstring girder, though this name more properly belongs to an obsolete form with no diagonals. Z and X are the spaces between the end loads and the reactions which, for clearness, are shown as pulling up; but the same reciprocal would result if the reaction were shown pushing up, and the letters X and Z were placed as dotted. This

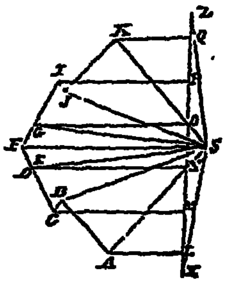

Fig. 72*a*.

form has the advantage of reducing the compression on the diagonal struts to a comparatively small amount. A great part of the shearing stress is taken by the curved upper boom; deeper girders can be profitably used of the bowstring than of the Warren type. The long and expensive struts in the latter form more than counterbalance

the saving to be obtained by increasing the depth beyond about $\frac{1}{12}$th of the span.

The diagonal bracing in the Warren and bowstring girders is sometimes arranged as in fig. 73; the girder is

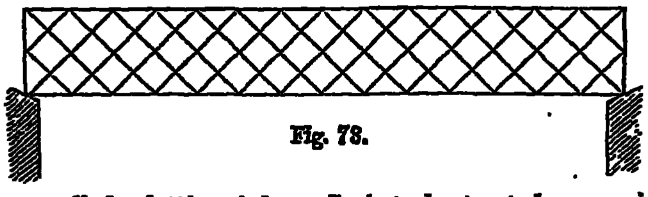

Fig. 73.

then called a lattice-girder. It is to be treated as a series of superposed Warren girders, each bearing its share of the load. This form has a slight advantage inasmuch as the diagonal struts are stiffened by being pinned to the ties where they cross.

Fig. 74 shows a very common and useful form of girder

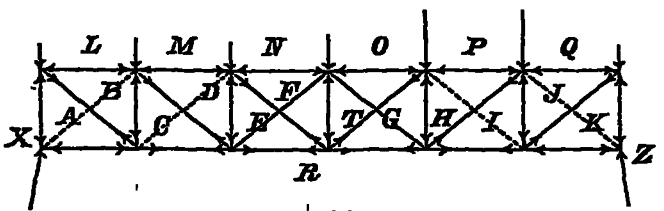

Fig. 74.

where the uprights between the top and bottom members are able to sustain both tension and compression, while the diagonals are only "semi-members," being flexible rods or bars. The reciprocal for this design is shown in fig. 74*a* with two joints more heavily loaded than the others. The members in fig. 74 which have no arrows on them are idle or unused, with this particular distribution of load. When the permanent load is considerable as compared with the passing load, the end or two end diagonals

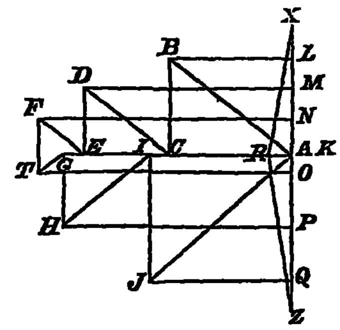

Fig. 74*a*.

shown dotted will not come into action with any distribution of load, and may therefore be omitted. This form is much used when wood is employed for the compression members. It has in every case the advantage that the struts in the bracing are shorter than in the Warren girder. The lettering is arranged so that only those spaces have letters which are divided by members actually in use under this particular load.

Figs. 75 and 75a show a modification of this truss for small spans, and its reciprocal when loaded on one joint;

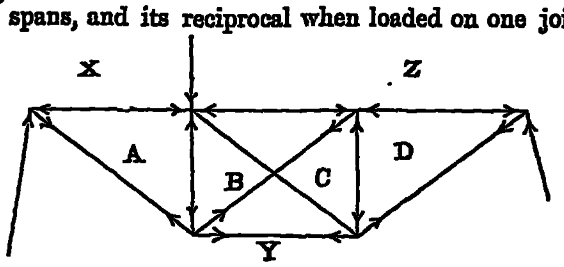

Fig. 75.

the lettering here also only suits the one distribution of load, and the idle members have no arrows on them.

§ 56. *Framed Suspension Bridges and Arches.*—These frames, like the girders, consist of top and bottom members, braced together by ties and struts. The bridge is a suspension bridge, if the frame is supported by inclined forces pulling outwards from the bridge as in fig. 76, and an arch is supported by forces pushing inwards as in fig. 77. The reciprocals of these two forms with the joints at the platform uniformly loaded are annexed. These reciprocals are drawn on the hypothesis that the direction of the thrust or pull is known; and this has been chosen in this case so as to reduce the stress on NG to zero, as would necessarily be the case if NG were omitted or cut. When this is not the case the direction of the thrust or pull at the abutments must be found in the manner explained below.

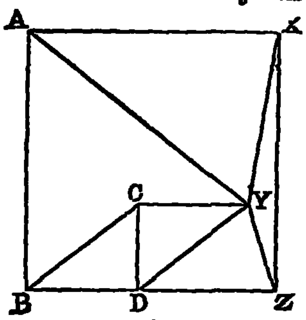

Fig. 75*a*.

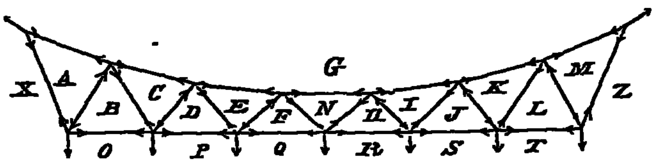

Fig. 76.

It is easy to design the bridge so that both the top and bottom members of the suspension bridge remain in tension, and both those of the arch in compression under all distributions of load. This would allow wire rope to be used for both members of the suspension bridge, and cast-iron or steel for both members of the arch. The stresses on the bracing are very uniform and small as compared with those on the diagonals of a girder.

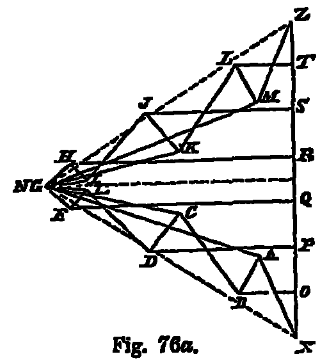

Fig. 76*a*.

Fig. 78 shows a slight modification of the design for a

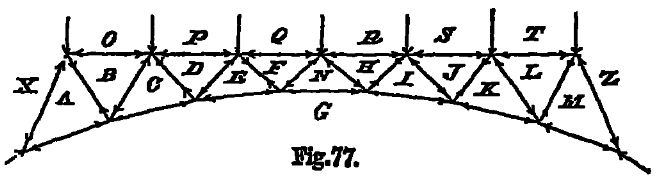

Fig. 77.

suspension bridge, very suitable for spans so large that the end struts in the preceding form would be inconveniently long. The reciprocal annexed is drawn for the case in which a double load is placed on half the bridge. The same design is suitable for an arch.

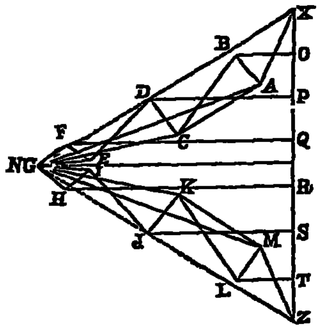

Fig. 77*a*.

The resultant thrust or tension at the supports of framed suspension bridges or arches can only be found by a method analogous to that already explained for the solid metal rib. This method was first given by Prof. Clerk Maxwell.

Consider any member A, fig. 79, of length L and cross-section a, made of a material having the modulus of elasticity E; under the action of a stress F, the length L will be altered by an amount—

$$\Delta L = F\frac{L}{Ea}.$$

Appropriate signs must be given to the arithmetical values of the force and the alteration of length; thus thrust and compression may be called negative, pull and extension positive. If every other member of the frame were absolutely rigid, the span S of the bridge would undergo an alteration ΔS. The ratio $\frac{\Delta S}{\Delta L}$ will depend merely on the geometrical form of the frame; let q be the value of this constant ratio, so that—

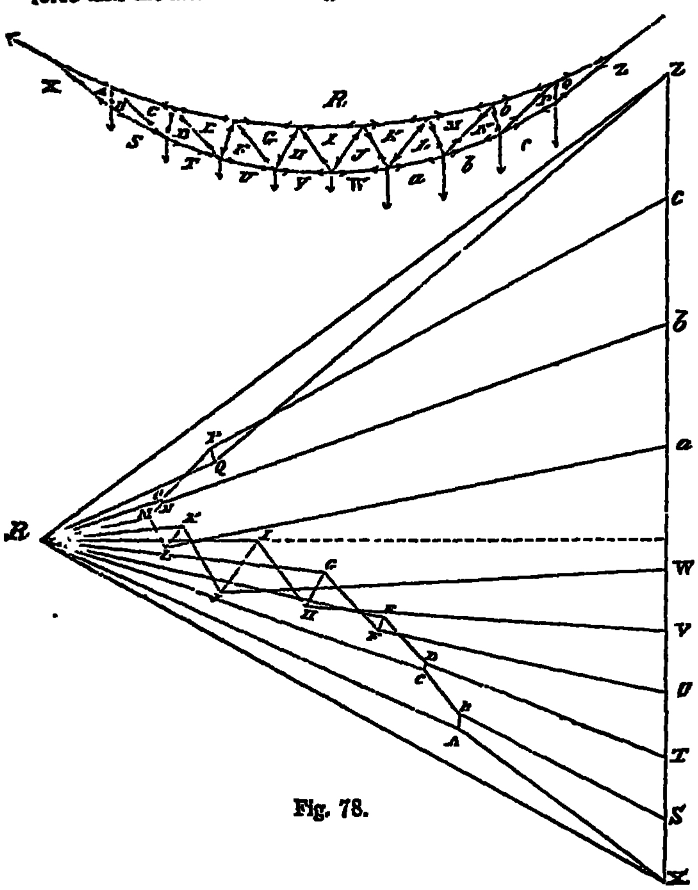

Fig. 78.

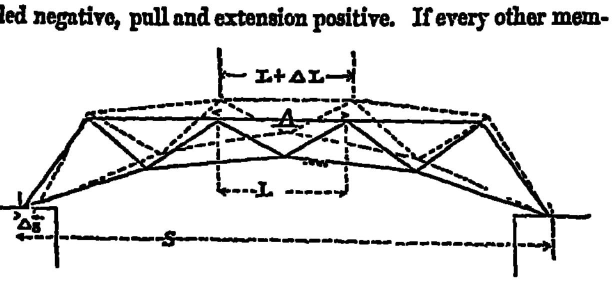

Fig. 79.

$$1. \quad \ldots\ldots \quad \Delta S = q\Delta L = qF\frac{L}{E.a}.$$

Let f be the force produced on the member A by a horizontal force h acting between the springings; then by the principle of virtual velocities we have—

$$f : h = \Delta S : \Delta L,$$

for we may consider the structure merely as a kind of lever, by which the force h exerts a force on A, the fulcrum being the joint opposite A; then the above proportion expresses the fact that the forces h and f are inversely proportional to the spaces which the ends of the lever would move through when a small displacement occurs. Thus we may write

$$f = qh.$$

Similarly let f_1 be the stress which would be produced on A by a vertical force v, applied at one springing, while the other springing was held rigidly so that the whole frame could not turn; the ratio between f_1 and v is constant, depending merely on the form of the frame, so that we may write—

$$f_1 = pv,$$

where p is a constant, to be found in the same manner as q; p may be defined as equal to the whole stress produced on the given member by a unit *vertical* force at the springing, and q as the whole stress produced on the same member by a unit *horizontal* force at the springing, the frame being held rigidly at the opposite abutment.

Then any thrust t at the springing having the vertical and horizontal components v and h will produce a stress F on A, equal to the sum of the stresses of f and f_1, or—

$$F = qh + pv.$$

Substituting this value of F in equation 1 we have—

$$2. \quad \ldots \quad \Delta S = (q^2h + pqv)\left(\frac{L}{Ea}\right) = eq^2h + epqv,$$

where $e = \frac{L}{Ea}$, a constant for each member.

Now, let the values of q, p, and e be calculated for every member of the frame; then, calling the whole elongation $\Sigma\Delta S = k$, we have—

$$k = \Sigma\,(eq^2h + epqv).$$

If the abutments do not yield $k = 0$, and for this case—

$$3. \quad \ldots\ldots \quad h = \frac{\Sigma epqv}{\Sigma eq^2}.$$

v is to be found as for a girder similarly loaded, and t, the required thrust or tension, is the resultant of h and v. The calculation is best made as follows:—Construct tables of the values of d and q for each member of the frame; the method of sections or moments will answer best for the top and bottom members, and that of reciprocal figures for the diagonals; assume a cross section for each member, based on a probable assumed value of t; for the required load make tables of epq and eq^2, or what is equivalent, when E is constant, make tables of the values of $\frac{pq^2}{a}$ and $\frac{q^2L}{a}$. The sum of eq^2 or $\frac{q^2L}{a}$ can then be made. If there be a load on one joint only, find the values of v and v_1, for the right and left abutments, then find $\Sigma epqv$, using the value v for all members to the right of the load, and v_1 for all members to the left of the load; equation 3 will now give the value of h for this single load.

The process of finding $\Sigma epqv$ must be repeated for each joint which is loaded, and the whole horizontal thrust due to the load on any number of joints will be the sum of the separate values of h. When the horizontal thrust is known, the thrusts t and t_1 are obtained at the two abutments by compounding the horizontal thrust with the vertical weight borne at that abutment. When t and t_1 are known, the stresses on each member are to be computed by reciprocal figures or any other convenient method. The process must be repeated for each combination of passing and permanent load, so as to find the maximum stress to which any member can be subjected. If the assumed cross sections are not suitable for these stresses, fresh cross sections must be assumed and the whole calculation repeated. The change in cross section will cause some change in the values of h, but this tentative process need seldom be gone through more than once.

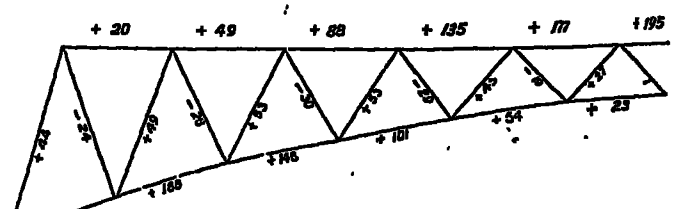

Fig. 80.

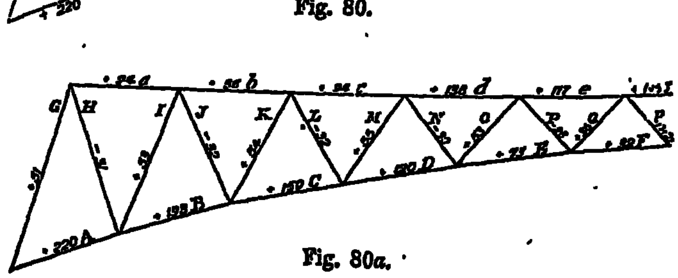

Fig. 80*a*.

Fig. 80 shows half the frame of a bridge for which the calculations have been made. The span is 120 feet, the rise 12 feet, and the truss 5 feet deep at the crown. The load assumed is 10 tons

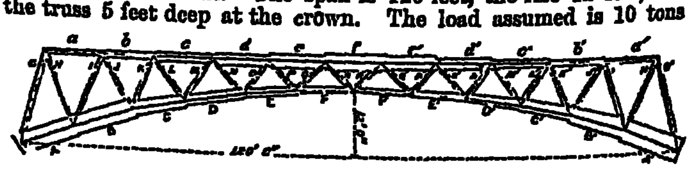

Fig. 81.

permanently on each top joint, and 10 tons of passing load. On fig. 80 are marked the stresses when the bridge is wholly covered with the passing load. On fig. 80*a* are marked the maximum stresses with any distribution of load. Figs. 81 and 82 show graphi-

cally the amount of metal required in this bridge and in a girder of the same span and 12 feet deep; the breadth given in the diagram to each member is proportional to the cross section required. The quantity of metal required for the girder exceeds that for the arch in the ratio of about 175 to 100: a similar calculation for a bowstring

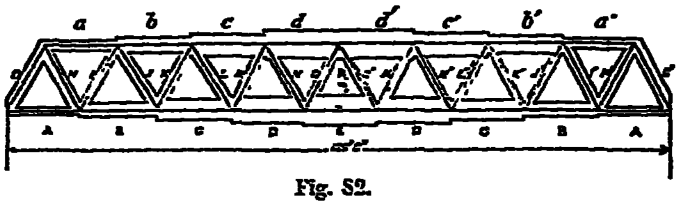

Fig. 82.

lattice girder 17 feet deep at the centre gives the ratio between the weights of metal required as 100 for the arch and 155 for the bowstring. Even these ratios understate the great advantage to be derived from the braced arch or suspension bridge for large spans, since they assume that the loads to be carried are the same, whereas the permanent load is in large spans much less for the lighter construction of bridge. The following table shows the probable weight in tons of several different types of trusses, assuming that the maximum intensity of stress on the metal in girders and arches is everywhere 4 tons per square inch, that the passing load to be carried is 1·4 tons per foot run, and that the practical weight is 25 per cent. in excess of the minimum possible weight if no metal were wasted, vide *Trans. R.S.S.A.*, vol. viii. p. 135. It must be remembered that the abutments for arches will in all cases be more expensive than those for girders; in small spans this expense will often outweigh the saving which could be effected in the superstructure by employing the arch.

TABLE XII.—*Weights of Trusses of different types.*

Span.	Weight of wrought iron Girder in tons.		Weight of wrought iron Bowstring, in tons.		Weight of wrought iron Suspension Bridge, and wrought iron or cast iron Arch, in tons.		Weight of wooden Arch, in tons.		Weight of Suspension Bridge, in tons. Strain 8 tons per square inch.

1600									2360	1·475
1800									3410	1·89
2000									4950	2·475

The framed arch is a very suitable form for wooden bridges. The ties are few and subject to insignificant strains. In designing a series of arches supported on piers care must be taken to provide for the thrust from loaded to unloaded arches across the pier at the springing.

§ 57. *Strength of Struts.*—When a strut or column is used as in framework to resist compression, it is usually so long in comparison with its cross section that it will bend and yield with a much less stress than would be required to crush the material. The strength of a strut of this kind can be approximately computed according to the following theory:—

Fig. 83.

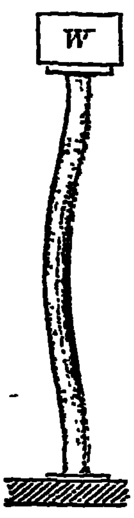

Fig. 84.

Let a strut with a cross section S be pinned or hinged at both ends, or let it have round ends, so that if it yields under compression it bends as in fig. 83. Let the cross section have two axes of symmetry, and let the section be such that the column will bend in the plane of one axis; let the depth of cross section measured in this direction be called d, and the breadth measured at right angles to the depth d be called b. Let the maximum or breaking load be called P, and the maximum deflection of the longitudinal axis of the strut from its unbent position be called v, this quantity being *analogous to the deflection in a beam.* The moment tending to produce flexure at the cross section where v is measured will be Pv. This moment must, as in the case of a girder, be equal to the moment of the elastic forces, which we already know to be—

$$u = \frac{2p_1 I}{d},$$

where p_1 and I have the same signification as for girders.

(I must be taken about the unstrained axis, or in other words about the axis running in the direction which has been called that of the breadth.) Hence we have—

$$Pv = \frac{2p_1 I}{d}, \text{ or } p_1 = \frac{Pvd}{2I};$$

but we also know that for beams of uniform cross section under similar internal stresses v is proportional to $\frac{l^2}{d}$; hence we have—

$$1. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad p_1 = a\frac{Pl^2}{I},$$

where a is a constant depending on the material only. Let $p_0 = \frac{P}{S}$ be the mean intensity of stress which would be produced if the load compressed all parts of the cross section equally, and let f_c as before be the ultimate strength of the material per unit of cross section, then, when the beam is on the point of yielding, we must have $f_c = p_0 + p_1$, or—

$$f_c = \frac{P}{S} + a\frac{Pl^2}{I},$$

and calling r the radius of gyration—

$$2. \quad . \quad . \quad . \quad . \quad f_c = \frac{P}{S}\left(1 + a\frac{l^2}{r^2}\right), \text{ or } P = \frac{f_c S}{1 + \frac{al^2}{r^2}},$$

from which f_c can be computed in terms of P and a, or P in terms of f_c and a.

The value of a does not change with a change in the design of the cross section; the values for cast iron, wrought iron, and wood determined by experiment are given in the following table, S being measured in square inches, P in lbs. The table also contains values of f_c.

TABLE XIII.—*Constants for the Strength of Struts and Pillars.*

	f_c.	a.
Cast-iron	80,000 lbs.	$\frac{1}{6400}$
Wrought iron	36,000 lbs.	$\frac{1}{9000}$
Dry timber	7,200 lbs.	$\frac{1}{750}$

When the direction of both ends of the column is fixed it must bend in the manner shown in fig. 84; if the curvature be uniform this would have the effect of reducing the deflection v to one-fourth of the amount caused by the same stresses when the ends are hinged, giving—

$$p_1 = \frac{aPl^2}{4I},$$

and

$$3. \quad . \quad . \quad . \quad f_c = \frac{P}{S}\left(1 + \frac{al^2}{4r^2}\right), \quad \text{or} \quad P = \frac{f_c S}{1 + \frac{al^2}{4r^2}}.$$

When one end is fixed in direction and the other hinged, the ultimate load which the strut can bear may be taken as a mean between the strength of two pillars of the same length and cross section, one having both ends fixed in direction and the other having both ends hinged; for similar cross sections r^2 is proportional to d^2, the square of the depth (measured in the direction of the shorter side or axis), thus the ratio $\frac{l^2}{r^2} \propto \frac{l^2}{d^2}$.

Let $n = \frac{d^2}{12r^2}$, and let $B = 3\frac{al^2}{d^2}$. Then from equation 2 we have for hinged ends—

$$4. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad P = \frac{fS}{1 + 4nB},$$

and from equation 3 for fixed ends—

$$5. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad P = \frac{fS}{1 + nB}.$$

n has a constant value for all similar cross sections, and B a constant

value for any given materials and any constant ratio of l to v. Table XIV. gives the values of B for a series of these ratios, and Table XV. gives the values of n for the most usual cross sections.

TABLE XIV.—*Value of* B (*lbs. and square inches*), *Strength of Struts and Pillars.*

$\frac{l}{d}$	B for Cast Iron.	B for Wrought Iron.	B for Strong Dry Timber.
10	·187	0·033	·25
15	·42	·075	·9
20	·75	·133	1·6
25	1·16	·208	2·5
30	1·69	·3	3·6
35	2·3	·408	4·9
40	3·	·533	6·4
50	4·68	·833	10·

TABLE XV.—*Values of* n, *Strength of Struts and Pillars.*

	n	
Square of side d, or rectangle with smallest side d..............	1	Hollow rectangle, thin sides	$\frac{1}{2}$	Circle, diameter d	$1\frac{1}{3}$	Thin ring, external diameter d	$\frac{2}{3}$	Angle iron, smallest side d............	2	
Cruciform, smallest breadth $=d$......	2	

It is of great importance that the connections between the several struts and ties *forming* a frame should be so designed that the stresses produced may be *axial*. If this is not done the maximum intensity of stress on the strut or tie may greatly exceed those computed on the principles explained in the present paragraph (*vide* § 8).

Mr Unwin in his lectures gives the following empirical rules for the strength of wrought iron struts:—

$$P_1=\frac{fS}{1+\frac{l^2}{ch^2}} \text{ for fixed ends, ... } 6.$$

$$P_1=\frac{fS}{1+\frac{4l^2}{ch^2}} \text{ for round ends, ... } 7.$$

where different values are given to f and c according to the different cross sections of the struts.

Rectangular bars	$c=2500$	$f=17$ tons.
Cylindrical bars	$c=3500$	$f=17·5$ „
Angle, T, cross, and charcoal iron	$c=900$	$f=19$ „

The following are Mr Hodgkinson's formulæ for the strength of cast-iron cylindrical pillars, the length of which is not less than thirty times the diameter:—Let P be the load which will produce failure, d the external diameter in *inches*, L the length in *feet*, and A a constant multiplier; then for solid pillars with either round or flat ends—

$$8. \quad . \quad . \quad . \quad . \quad . \quad . \quad P=Ad^{3·6}\div L^{1·7}.$$

The value of A for rounded ends is 14·9 tons, and for flat ends 44·16 tons. Similarly for hollow pillars of internal diameter $d_{\prime}$ we have

$$9. \quad . \quad . \quad . \quad . \quad . \quad . \quad P=A(d^{3·6}-d_{\prime}^{3·6})\div L^{1·7},$$

where for rounded ends A is taken as 13 tons, and for flat ends 44·3 tons.

When the length is less than thirty times the diameter, let P be the ultimate load calculated by equations 8 and 9, and let $P_{\prime}$ be the load which would crush a short block of the same sectional area S; *i.e.*, let $P_{\prime}=49S$; let $P_{\prime\prime}$ be the actual ultimate strength, then, according to Professor Hodgkinson's experiments,

$$10. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad P_{\prime\prime}=\frac{4PP_{\prime}}{4P+3P_{\prime}}.$$

For rectangular struts of oak and pine, the smallest side being denoted as before by $d_{\prime\prime}$ Hodgkinson gives the formula—

$$11. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad P=A\frac{d^2}{l^2}S,$$

where A$=$3,000,000 lbs. The same unit must be employed for d and l, and S must be expressed in square inches. This formula can only give a rough approximation to the truth. In short beams the formula in § 5 would give a smaller strength than equation 11. This smaller value is, then, the true measure of the strength.

VI. COMPOUND STRUCTURES.

§ 58. Many bridges have been built with superstructures such that the stresses on the several parts or members cannot be computed by the rules hitherto given. These superstructures are generally constructed by superposing two or more types so as to form a compound structure capable of acting at once say as an arch and as a girder. These bridges may be called compound bridges. The designs are usually unworthy of imitation. Mr Robert Stevenson's original design for the Britannia Bridge, in which the great girder would have been partly supported by chains, is an example of this type of structure in which the two parts are clearly visible. Many wooden American bridges are trusses which almost defy analysis, the designs being, however, obviously suggested by an attempt to combine at least two of the three main types of bridges. No advantage whatever is gained by a combination of this kind; on the contrary great disadvantage is almost sure to follow its adoption, namely, that it will be impossible that each part of the structure should, under all circumstances, carry that portion of the load which the designer entrusted to it. For suppose a bridge constructed partly as a girder and partly as a suspension bridge, the girder being very stiff and deep and the chain perfectly flexible with considerable dip. Let the chain and girder be each fit to carry half the passing load. It is perfectly conceivable that the deflections of the two should be so different that the girder would, under the actual load, break before the chain was sensibly strained, or the difference in the relative dip of the chain and depth of the girder might be such as to cause the former to give way first. Even if the two were so designed that at a given temperature each should take the designed share of the load, a change of temperature would entirely alter the proportion borne by the two parts of the structure. A few forms are free from this defect, and these will now be described.

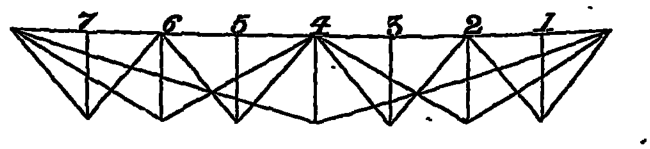

Fig. 85.

§ 59. *Fink Truss.*—This truss (fig. 85) has been much employed in America. The upright struts, numbered 1 to 7, divide the span into eight equal parts. If a weight w rests on the top of each strut the whole truss may be looked upon as made up of seven distinct and independent trusses superposed on one another; strut 4 is used seven times, and is compressed with a total force of $4w$. Struts 2 and 6 are used three times, and each compressed with a total force of $2w$. Struts 1, 3, 5, and 7 are used once, and each compressed with a force w. The stresses on the inclined ties are at once got from the compression of the strut by the resolution of forces; and the stress on the upper member or boom is the sum of all the pulls on the ties resolved horizontally;

the boom is uniformly strained over its whole length. This truss would not be so light as a Warren girder if both were made of the same depth, and if the end struts in the Warren girder did not require to be much stiffened in consequence of their great length. The Fink truss is, however, generally made in practice more cheaply than the Warren girder, because the depth of a girder practically depends on the greatest length of strut which is admissible, and for equal lengths of strut the Fink truss gives a deeper beam than the Warren girder.

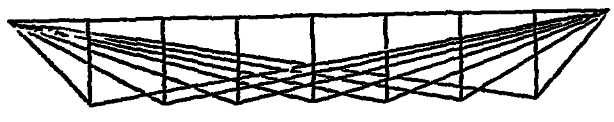

Fig. 86.

§ 60. *Bollman Truss* (fig. 86).—This truss is the result of superposing seven simple frames consisting of a top member, a strut, and two ties. The stresses are easily computed. It is one form of the old false suspension bridge already alluded to (§ 34), with the difference that the top member replaces the horizontal resistance at the points of support. The defect of this truss is that two ties supporting any strut except the central one are of unequal length; expansion or extension, consequently, affects these unequally. It is inferior to the Fink truss.

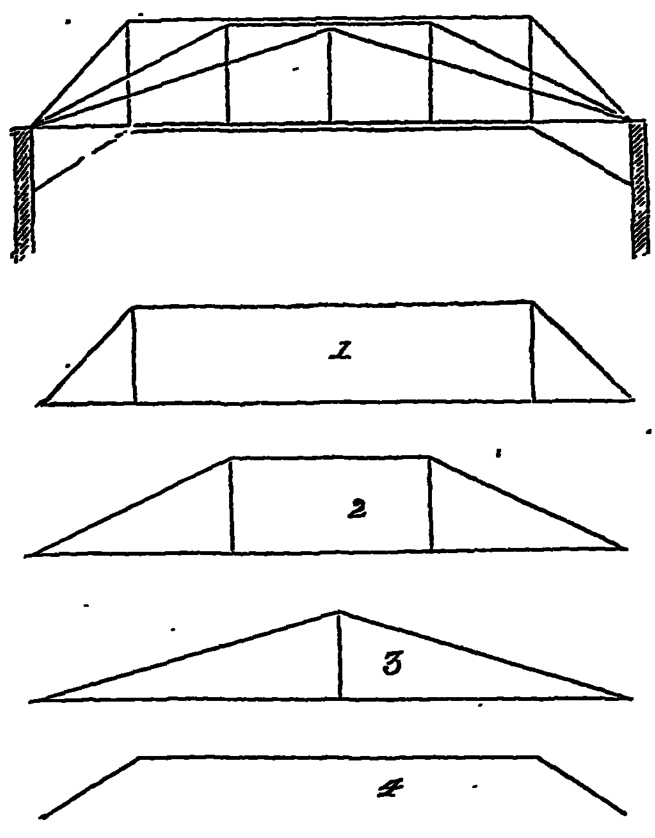

Fig. 87.

§ 61. *Schaffhausen Truss.*—The famous wooden bridge of Schaffhausen (fig. 87, see also § 76) is in its main parts a compound bridge, composed by superposing a series of simple frames of the type shown in 1, 2, 3, and 4. Nos. 1 and 2 are imperfect frames, *i.e.*, if the joints were flexible they would collapse in consequence of the want of the diagonals across the centre parallelogram. The stiffness of the joints supplies this want.

§ 62. *Dredge's Suspension Bridge.*—This bridge differs from the usual suspension bridge in having the suspending rods inclined, and in the use of a lower member, which may be a compression member transmitting a thrust to the piers, as in 88*a*, or a tension member, as in 88*b*, with a

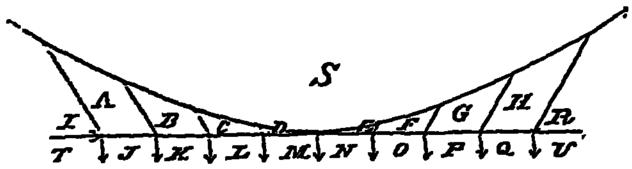

Fig. 88*a*.

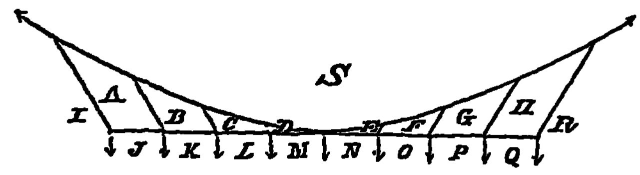

Fig. 88*b*.

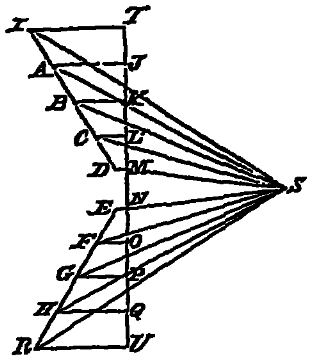

Fig. 88*c*.

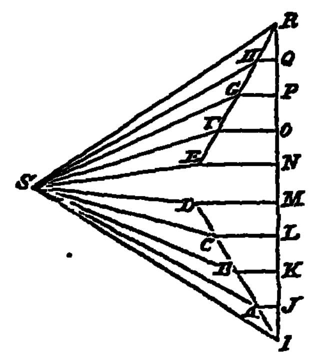

Fig. 88*d*.

maximum tension at the centre. Fig. 88*c* and fig. 88*d* show the reciprocal figures corresponding to those two cases. This bridge is somewhat stiffer than the ordinary suspension bridge, but is far inferior to the complete framed bridge.

§ 63. *Arch or Suspension Bridge, hinged at Abutments and Centre.*—Figs. 89 and 90 show two designs of considerable merit, consisting of two frames (the shape of which might vary considerably) hinged together at A, and

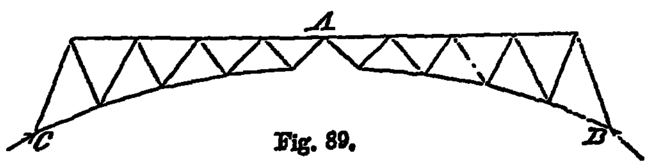

Fig. 89.

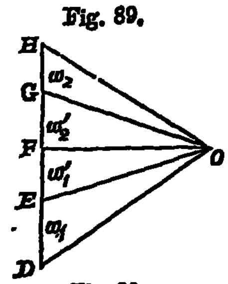

Fig. 89*a*.

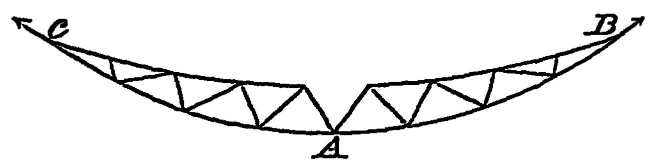

Fig. 90.

supported on hinges at B and C. The direction of the sustaining forces at A and B is to be determined as for a simple pair of beams hinged at A, B, and C. Find w_1 and w_1', the proportions of the load on AC borne by C and A re-

spectively; and w_2 and w_2' the proportions of the load on AB borne by B and A respectively. Then draw the line of loads DEFGH as sketched (fig. 89*a*). From E and G draw lines parallel to AC and AB respectively, meeting in O. Join OD and OH. OD and OH represent in magnitude and direction the thrust on C and on B. OF is the stress on the pin at A. These thrusts being known, the stress on each member of each frame can be easily computed by a reciprocal figure or otherwise. This form is only inferior to the true framed arch or suspension bridge inasmuch as it is incapable of balancing the thrust due to the passing load on neighbouring spans. It is superior to the framed arch and suspension bridge inasmuch as it cannot be strained by any change of temperature.

VII SUBSTRUCTURE.

§ 64. *Preliminary.*—The substructure of a bridge comprises the piers, abutments, and foundations. These portions of the bridge usually consist of masonry in some form, including under that general head stone masonry, brickwork, and concrete. Occasionally metal work or woodwork is used for intermediate piers.

When girders form the superstructure, the resultant pressure on the piers or abutments is vertical, and the dimensions of these are simply regulated by the sufficiency to bear this vertical load.

When arches form the superstructure, the abutment must be so designed as to transmit the resultant thrust to the foundation in a safe direction, and so distributed that no part may be unduly compressed. The intermediate piers should also have considerable stability, so as to counterbalance the thrust arising when one arch is loaded while the other is free from load.

For suspension bridges the abutment forming the anchorage must be so designed as to be thoroughly stable under the greatest pull which the chains can exert. The piers require to be carried above the platform, and their design must be modified according to the type of suspension bridge adopted. When the resultant pressure is not vertical on the piers these must be constructed to meet the inclined pressure. In any stiffened suspension bridge the action of the pier will be analogous to that of a pier between two arches.

§ 65. *Stability.*—When the magnitude and direction of the thrust borne by a pier or abutment at the springing are known, the stability of any series of masonry blocks forming the pier or abutment may be studied by drawing lines showing the direction and magnitude of the resultant force on each joint. This may be done as for the voussoirs of an arch. The thrust on the upper block may be compounded with the weight of that block, the resultant compounded with the weight of the next, and so forth, until the direction and magnitude of the thrust on the rock or earth foundation is determined.

A better method of making the drawing is shown in fig. 91; find the centre of gravity $C_{\prime}$ of block 1, the centre of gravity $C_{\prime\prime}$ of blocks 1 and 2 treated as a single mass, similarly $C_{\prime\prime\prime}$ for blocks 1, 2, and 3 Let AT be the direction of the thrust on the top block, and $C_{\prime}B_{\prime}$ a vertical line though $C_{\prime}$ cutting AT in $B_{\prime}$; let $B_{\prime}D_{\prime}$ be the direction of the resultant of t, the thrust acting in the line AT, and $w_{\prime}$ the weight of the first block acting in the line $C_{\prime}B_{\prime}$; and let $D_{\prime}$ be the point where the direction of this resultant cuts the first joint; similarly let $B_{\prime\prime}D_{\prime\prime}$ be the direction of the resultant of t and the weight $w_{\prime}+w_{\prime\prime}$ of the first two blocks; $B_{\prime\prime\prime}D_{\prime\prime\prime}$ the direction of the resultant of t compounded with the weight $w_{\prime}+w_{\prime\prime}+w_{\prime\prime\prime}$ of the three first blocks, &c., &c. This method of proceeding gives the direction and magnitude of each force and centre of pressure D independently of the values obtained for the preceding joints. For stability the line BD must not make a greater angle with the normal to the joint than the angle of repose; and the point D must nowhere fall beyond the edge of the joint; for strength and safety the point D might be required to fall within the middle two-thirds of the joint, or within the middle three-quarters. The theory by which the joints furthest from the centre of pressure would open when the centre of pressure leaves the

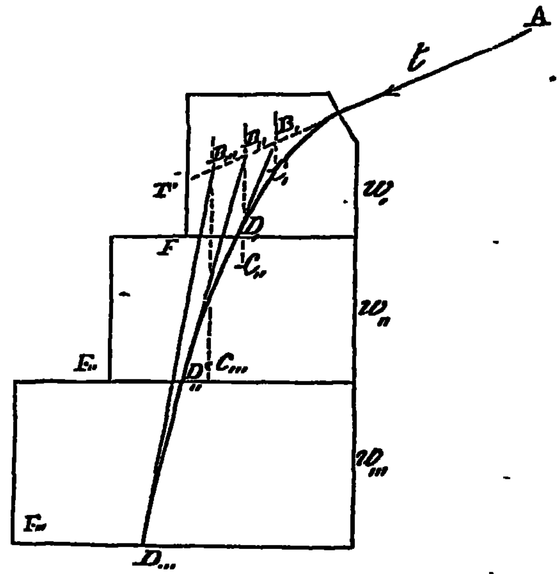

Fig. 91.

middle third cannot apply to such a structure as a masonry abutment, all parts of which are bonded together. Professor G. Fuller calculates the thickness of abutments by the following empirical rule, deduced from many practical examples:—Let c = half the span in feet; d = versed sine in feet; t = thickness of abutment at springing; then, for flat arches, in which the span does not exceed 150 feet, and the ratio of the rise to the span is not less than 116, we may write $t = \cdot17\left(\frac{c^2}{d} + d\right)$. From the springing to the base the abutment may have a batter of 1 in 4. This gives an abutment the cubic capacity of which will be sufficient, but it may with advantage be divided into abutment proper and counterforts; in semicircular arches t should be taken as the thickness of the abutment at a height above the springing equal to two-thirds of the radius. The maximum intensity of stress on the stone at the edge F might be approximately found by the theory explained in § 8. This theory finds a useful application in calculating the maximum intensity of stress which a given foundation might produce on the earth

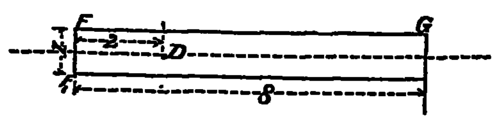

Fig. 92.

or rock supporting it. Thus, let the section of the foundation under consideration be 1 foot in breadth, 8 feet in length from F to G, as shown in plan, fig. 92; let the centre of pressure D be 2 feet from FF, and let the total resultant thrust be about 16·5 tons, inclined so that the horizontal component is 4 tons and the vertical component 16 tons, then the mean vertical intensity of pressure per square foot is $\frac{16}{8} = 2$, and the maximum intensity along the line FF, is by equation 2, § 8—

$$2\left\{1+(4\times2\times8)\frac{12}{512}\right\} = 5,$$

this maximum intensity being $2\frac{1}{2}$ times as great as the mean intensity. Obviously, although for the sake of appearance the courses of masonry in the abutment of an arch may be left horizontal in the face, the stability is increased by inclining them at a proper angle, so that they lie normal to the thrust.

The stability of abutments may be tested by taking moments round points in the joints selected as the points beyond which the thrust must not come. The same methods apply to the ancherages of suspension bridges, and to intermediate piers, which are intended to take a given horizontal thrust. When metal or wooden piers are adopted their weight will generally be insignificant, and such as may be neglected in calculating their stability. Metal-work piers or wooden piers usually consist of wrought or cast-iron frame work, and the stress on each part of the frame, as well as the resultant stress on the foundations where each upright member reaches it, is

easily calculated by the method of reciprocal figures or otherwise.

Occasionally metal piers are continuous metal structures, such as cast-iron cylinders. The maximum intensity of stress can then be calculated by resolving the thrust on the upper part of the pier into a horizontal and a vertical component, calculating the bending moment produced on each horizontal cross section by the horizontal component, and adding the intensity of stress caused by this bending moment to the mean intensity caused by direct compression. The manner in which any metal-work pier is held by its foundation against a bending moment will require special consideration; the resultant pressure should always fall well within the base.

§ 66. *Practice.*—In the design of the usual masonry bridge the thickness of the pier is generally determined by practical considerations. In small arches the pier is made thick enough to allow the two rings of the two abutting arches to spring from the pier without interfering with one another, a clearance of about half a brick being often allowed between the two rings. In larger arches the piers will generally be found to vary in thickness from $\frac{1}{8}$th to $\frac{1}{10}$th of the span, with a slight batter (*i.e.*, with walls spreading outward towards the base). In very old bridges piers are sometimes found equal in width to the opening of the arch. In large bridges, or with very high piers, care must be taken that the pressure per square foot on the masonry or foundation does not exceed a safe value. The brickwork in the piers of Charing Cross bridge is subject to a compression of 9 tons per square foot; four or five tons is a much more usual load. Eight tons per square foot may be considered a maximum for rubble stone-work, and perhaps 20 tons for the best dressed ashlar. Strong concrete may be trusted with 3 tons; firm rock foundations with 9 tons, soft sandstone with 2 tons, and firm earth with from 1 to $1\frac{1}{2}$ tons. The depth of the first course below the surface (on dry land) should not be less than 3 feet in sand and 4 feet in clay.

When framework, either of wood or iron, is used as a pier, care must be taken by cross-bracing to provide against the effect of wind and vibration.

§ 67. *Site.*—The site proposed for a pier must be carefully examined by borings; the ground should be uniform, for if a pier rests partly on one formation and partly on another, unequal settlement will certainly occur, even if the weaker formation be such as would have been amply strong enough to bear the pressure had the pier been wholly founded upon it. Solid rock may be considered the best foundation, but where rock is broken up by cracks or other inequalities it is inferior to such formations as uniform gravel, chalk, and some kinds of sand and clay. These foundations may be described as incompressible. The worst foundations are afforded by those formations which can be compressed or squeezed out sideways by the imposition of weight. Muddy earth, certain clays, and certain sands are of this nature. Alternate beds of stone and slippery clay are very treacherous. The foundation should be dressed level so that the masonry may everywhere start from the same height, and therefore settle equally. Unavoidable inequalities are better filled up by concrete than by masonry.

For foundations in water it is very important that the ground should not be such as can be scoured away by the current or wash of the water; many bridges have failed by the undermining of the piers due to this cause. Special precautions, to be presently described, must be taken against the effects of the scour if the soil itself is not of a sufficiently resisting nature. The piers must be so placed and formed that the obstruction to the flow of water may be as small as possible and the effect which the piers will have in altering the level of the stream above and below the bridge must be considered. Data as to the maximum flood waters to be provided for must be examined; and provision must in some climates be made against ice by suitable cut-waters or fenders, an example of which is given in fig. 93, showing a pier of the Victoria Bridge, Montreal.

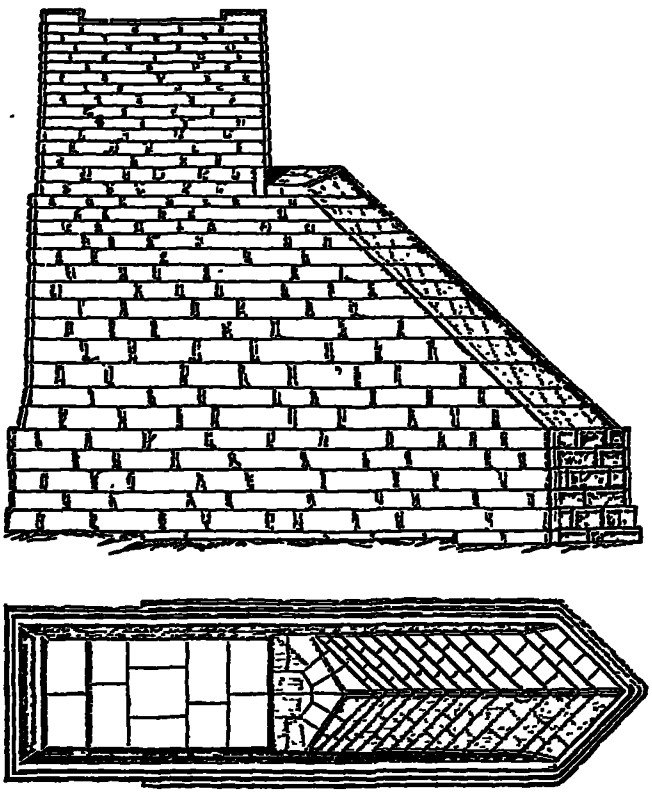

FIG. 93.—Side Elevation and Plan of Pier.

§ 68. *Mode of Founding in Water.*—The chief difficulty met with by an engineer about to erect a large bridge over a deep stream is to secure a sound foundation for the piers. The following are some of the principal methods of building piers in or under water:—

Cofferdams.—Cofferdams are embankments or dams which surround the site so as to exclude the water from it. They are formed in general by driving two rows of piles round the site so as to enclose between them a water-tight wall of clay puddle; in depths of less than 3 or 4 feet, where there is little current, a simple clay dam may be used. In greater depths, the timber walls consist of guide piles at intervals, with some form of sheet piling between them; in extreme depths the timber walls may be composed of stout piles driven in side by side all round. The dam must be sufficiently strong to bear the pressure of the water against the outside when the space enclosed has been pumped dry. Rankine states that the common rule for the thickness of a cofferdam is to make it equal to the height above ground if the height does not exceed 10 feet, and for greater heights, to add to 10 feet one-third of the excess of the height above 10 feet. The "Cours de Ponts" at the school of the Ponts et Chaussées, states that a cofferdam need never be made of greater thickness than from 4 to 6 feet, as the interior can always be sufficiently stayed inside. This method of founding is now seldom practised; it is costly and causes great obstruction in the stream.

Caissons.—Some foundations have been constructed as follows:—A level or nearly level bed was prepared in the stream by digging or by driving piles and sawing off the heads at a uniform depth; a huge timber box, called a caisson, was then filled with masonry, and sunk on the foundation thus roughly prepared. This method is now abandoned. It was peculiarly liable to danger from the scour of the stream. The name caisson is also sometimes

applied to a mere frame with wooden walls which is floated to the site of the pier, and there sunk so as to form an enclosure, inside which concrete can be shot and can set undisturbed by the wash of the water.

Concrete in a shell is a name which might be applied to all the methods of founding a pier which depend on the very valuable property which strong hydraulic concrete possesses of setting into a solid mass under water. The required space is enclosed by a wooden or iron shell; the soil inside the shell is removed by dredging, or some form of mechanical excavator, until the formation is reached which is to support the pier; the concrete is then shot into the enclosed space from a height of about 10 feet, and rammed down in layers about 1 foot thick; it soon consolidates into a permanent artificial stone. The shell,

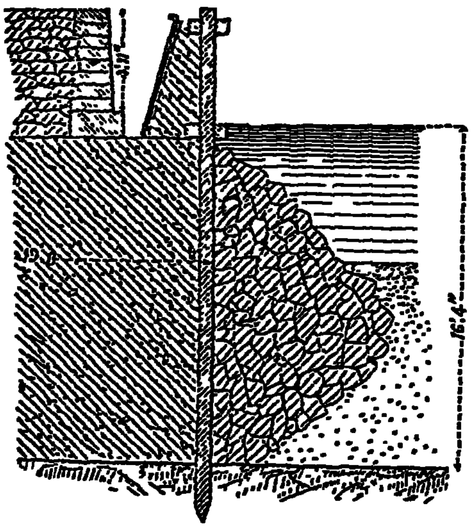

Fig. 94.

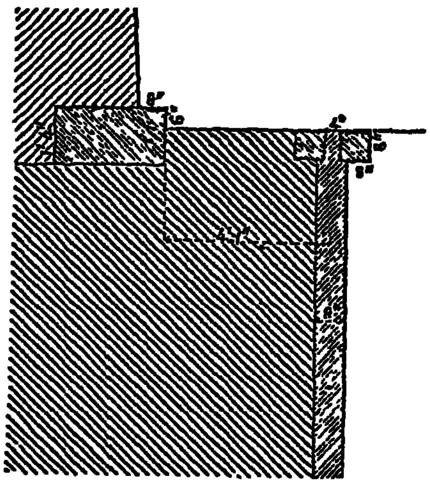

Fig. 94a.

unless of small size or very strong form, requires to be braced to meet the outward pressure of the concrete. The

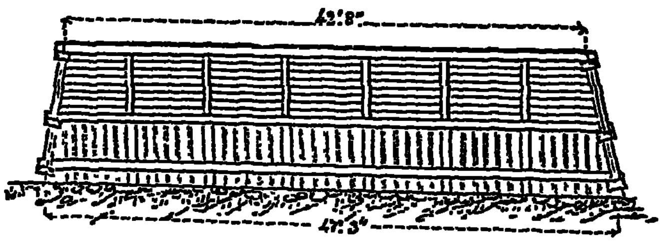

FIG. 95.—Caisson used for a Bridge over the Cher.

concrete used for this purpose is often called béton, to distinguish it from inferior mixtures used for foundations on land. It may consist of angular stones $1\frac{1}{2}$ to 2 inches diameter, mixed with strong hydraulic mortar in the proportion of from one to two volumes of stones with one of mortar; the final volume may be from $\frac{4}{5}$ to $\frac{5}{6}$ of the unmixed materials. Béton used at Biarritz consisted of one part Portland cement, two parts sand, and three parts broken stones; at Genoa one part rich lime, two parts pozzuolana, three parts broken stones.

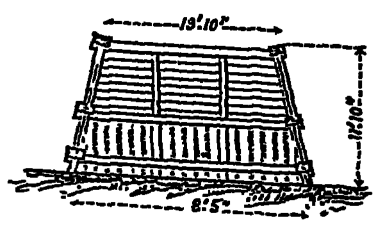

Fig. 95a.

Fig. 94 shows a section of foundations constructed by filling a casing of piles with concrete in this manner; the shell is protected against scour by large stones heaped round the outside, part of the loose earth having been removed by digging. Fig. 94a shows the manner in which the concrete foundation was finished after removal of the temporary external wall shown in fig. 94.

Figs. 95 and 95a show a longitudinal elevation and cross section of a wooden shell, or caisson without a bottom, intended to be sunk to receive concrete. Cast-iron guide piles and sheet piling are also used for this class of foundation.

Cast-iron tubular shells are now frequently employed; the tube forms a large hollow pile, which may descend into the ground by its own weight, or by added weight while the soil inside is removed by some kind of dredge or excavator, such as Milroy's, worked from the surface. When the lower edge of the shell has penetrated the formation to be used as a foundation, the water inside may be pumped out if the soil forms a water-tight joint, or the shell may simply be filled up with concrete shot into the enclosed water. The piers of Charing Cross bridge (fig. 96) were constructed in this way; the excavation inside the tube (14 feet diameter), was carried on by divers with helmets until the shell had entered a few feet into the London clay. The water was then pumped out and excavation continued; the cylinders were loaded with about 150 tons to sink them to the final depth.

Compressed air is now very generally employed inside a metal shell for those foundations in which the excavation requires the presence of workmen at the bottom of the shell. The metal shell is open at the bottom, but air-tight and water-tight at all other points; there is a chamber called an *air-lock* at the upper part. This "air-lock" serves for the exit and entrance of the workmen and materials; the air in this comparatively small space is lowered to the pressure of the atmosphere before the chamber is opened for the passage of men or materials to the open air; the air is again compressed in the air-lock before it is opened for communication with the body of the shell in which the air is permanently kept at such a pressure as will keep the water down to the required level. The shell thus acts as a diving bell acts. It is found that men cannot in general be safely employed under a greater pressure than two atmospheres above the ordinary atmospheric pressure, corresponding to a depth in water of about 65 feet. The centre pier of Saltash Bridge was, however, in 1855 by this plan carried down to a depth of 87 feet 6 inches below high water. Recently the foundations of St Louis bridge over the Mississippi have by the same method been established at a depth of

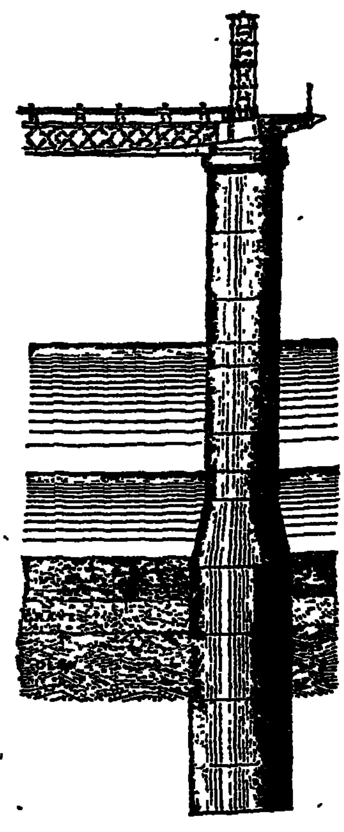

FIG. 96.—Cylinder, Charing Cross Bridge.

110 feet from the surface of the water. Figs. 97 and 97 A show the pier of the bridge of Argenteuil. Excavation was carried on in the lower chamber, the roof of which was very strongly built of metal, and served as the foundation for masonry and concrete built up round an inner tube, serving as a passage for men and materials to the upper chamber and "air lock." This lock is formed of two concentric cylinders of 3·9 feet and 10·8 feet diameter respectively (fig. 97*a*). The annular space was divided by two vertical partitions; the doors of communication (which were air-tight) were 1·8 feet wide and 2·14 feet high. A small engine worked the hoist by a stuffing-box passing through the shell. A safety-valve is of course required. The upward pressure of the air requires to be counterbalanced by weights. In the Argenteuil bridge this necessary weight was afforded by the masonry built in the tube as the tube sank. This plan seems preferable to the method of loading the shell externally with pig or railway iron. Frequently, owing to the tenacious nature of the soil, the water cannot be driven out below the tube, and in that case a syphon must be provided passing out at the top. The Argenteuil tube was sunk at a mean rate of about 18 inches per diem. This method is not confined to cylindrical tubes. Fig. 98 shows the method employed in building the piers of the bridge at Kehl over the Rhine. In this case four rectangular working chambers were sunk side by side and bolted together; each chamber communicated with the surface by two air-passages, and one central elliptical passage which remained full of water. This central passage served for the exit of the excavated material. A mass of concrete was built resting on the working chambers, and contained by wooden framework. The concrete was added at the top above water as the foundations gradually sank. At Mantes and Chalons wrought iron caissons, shaped like the usual masonry piers, have been sunk by analogous methods.

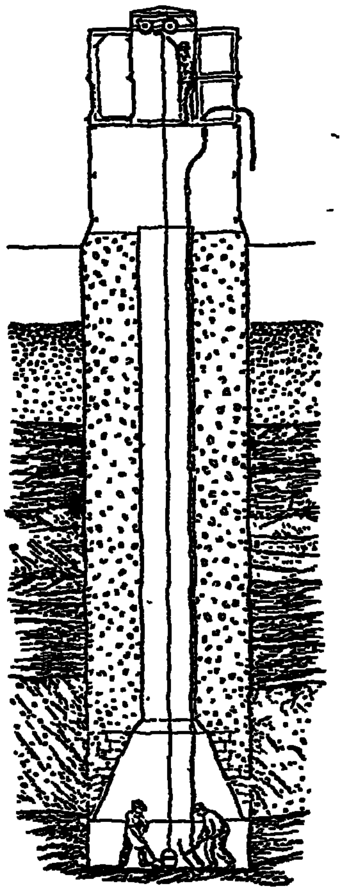

FIG. 97.—Foundations, Bridge of Argenteuil.

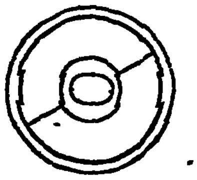

Fig. 97*a*.

The method of sinking cylinders by compressed air was invented by Mr Triger in 1841, and was first used on a large scale by Mr Hughes at Rochester. The tubes at this bridge were designed to be sunk by having the air *exhausted* inside the tube, a system invented by Dr Potts.

§ 69. *Piles* are used either to enclose a space or to bear part of the weight of a structure; for the former purpose a wooden pile may be a round or square pointed piece of timber, 6 or 9 inches in diameter and 8 or 12 feet long. Bearing piles may be of any dimensions which can practically be procured, and several lengths of timber are often jointed so as to form one long strut. The point is armed with metal, and the head protected by a metal ring, which prevents it from spreading when struck by the rammer which drives the pile. Bearing piles are usually placed at a distance from centre to centre not less than 2 feet 6

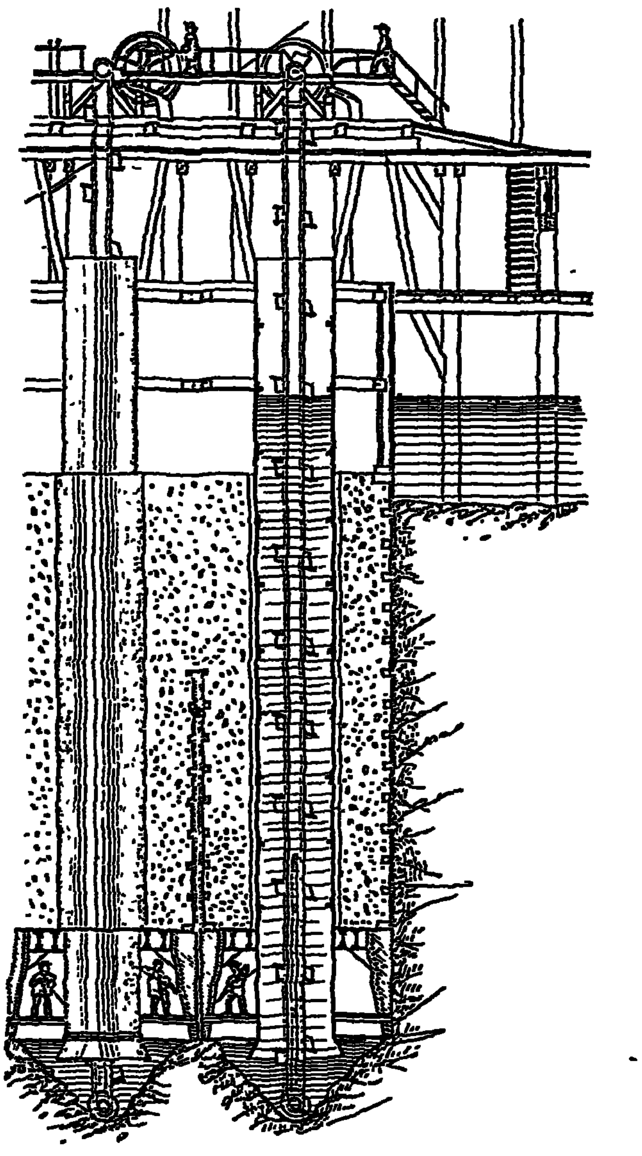

FIG. 98.—Foundations, Bridge of Kehl on the Rhine.

inches or more than 4 feet; 3 feet is a common distance. The diameter of bearing piles varies from 9 inches to 20 inches; a pile may be considered to be driven home when, with thirty blows of a ram weighing 800 lb and falling 5 feet, it does not move $\frac{1}{5}$th of an inch (Rankine). A French rule gives as a limit $\frac{1}{5}$ inch motion with twenty-five blows from a ram weighing 6 cwt. and falling 4 feet 3 inches. A pile which does not move more than this will bear from 600 to 1000 lb per square inch. This would give a load of 50 tons for a 13-inch pile; if, as is more usual, the load be only 8 or 10 tons for a 13-inch pile, the ultimate rate of descent may be three, four, or five times as much as the above.

Piles are used as foundations in those grounds which are compressible, or which would be squeezed out from beneath masonry under the weight to be borne. The wooden bearing piles are usually sawn off so that all the heads may be level, and a wooden grating or platform rests on the heads, over which the concrete or masonry pier may be built; in other cases the piles come up for some distance into the concrete. An external row of wooden piles is not unfrequently employed as a precaution against scour, but these should always be further protected by a stone bank, which will continue to protect the pier if the piles decay. A

more thorough protection against scour is provided by covering the centre bed of the river with a concrete or stone

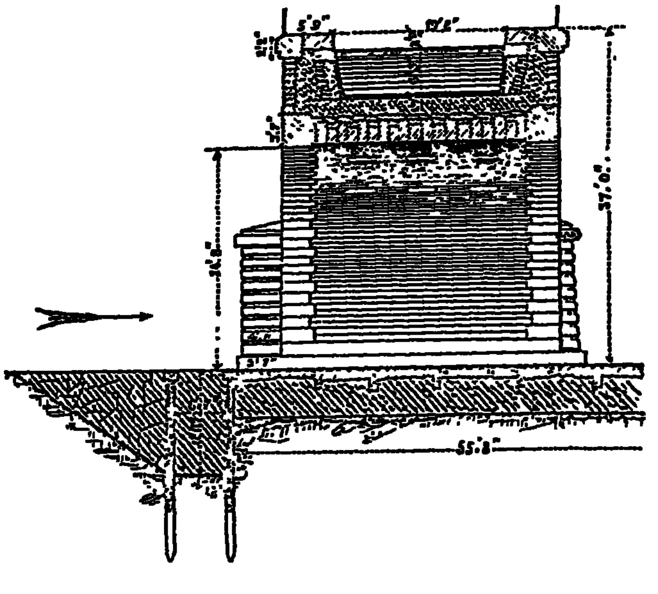

FIG. 99.—Aqueduct of Guétin over the Allier.

floor, as in fig. 99, representing a pier of the aqueduct crossing the Allier at Guétin.

Cast-iron guide piles (usually hollow tubes) are used for the same purpose as wooden guide piles. They may be cast with grooves down one edge in which sheet piling is held. Cast-iron and wooden piles are frequently used as part of the open-work metal or wooden framing of piers. In situations where these piles are not liable to injury by ice, floating timber, or barges, this construction is very economical. Fig. 4, Plate XIX. shows the Crumlin viaduct, with piers of this character, the construction of which will be more fully described in paragraph 79

Fig. 100 shows the Portage bridge (234 feet high) spanning the Genesee River, in the State of New York. The piers are large wooden frames.

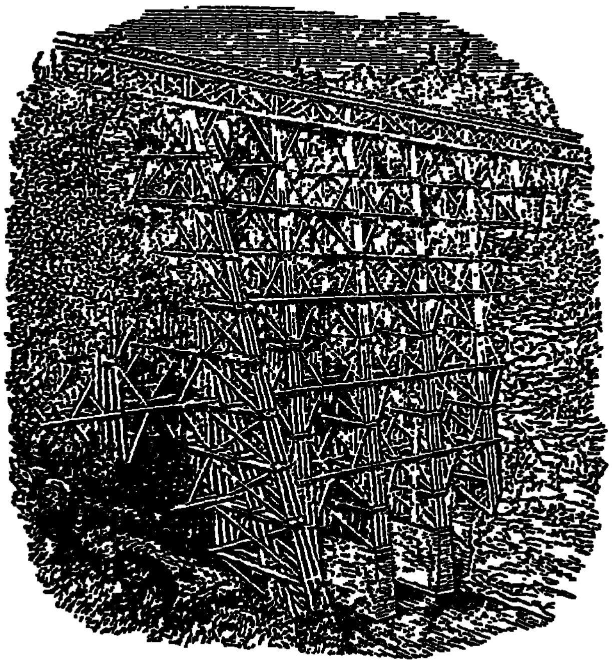

FIG. 100.—Portage Bridge.

§ 70. *Screw piles* are cast-iron piles which are screwed into the soil instead of being driven in. At their end is fixed a blade of cast-iron from two to eight times the diameter of the shaft of the pile; the pitch of the screw varies from one-half to one-fourth of the external diameter of the blade. The pile is turned by levers radiating from its head. In one example of their use (Rankine) the pile was screwed in by four levers, each 40 feet in length, with eight bullocks harnessed to it. The screws were 4 feet 6 inches in diameter, and the working load borne by them was 100 ℔ per square inch. The piles were screwed from 20 to 45 feet deep in earth.

Disc piles have been used in sand. These piles had a flat flange at the bottom, and water was pumped in at the top of the pile, which was weighted to prevent it from rising. Sand was thus blown or pumped from below the piles, which were thus easily lowered in ground which had baffled all attempts to drive in piles by blows. In ground which is of the nature of quicksand, piles will often slowly rise to their original position after each blow.

§ 71. *Wells.*—In some soils foundations may be obtained by the device of building a masonry casing like that of a well and excavating the soil inside; the casing gradually sinks and the masonry is continued at the surface. This method is applicable in running sands. The interior of the well is generally filled up with concrete or brick when the required depth has been reached, but in some cases a mere floor or inverted arch would be preferable.

VIII. EXAMPLES.

§ 72. The task of selecting a limited number of bridges

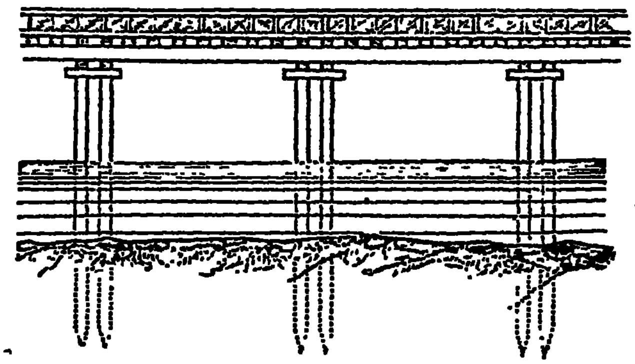

FIG. 101.—Pons Sublicius.

which shall represent the gradual progress in the art of construction and illustrate our present practice is one of much difficulty. Many very admirable and interesting structures must necessarily be passed over in silence, and space will not admit of full details being given even of those bridges which are noticed.

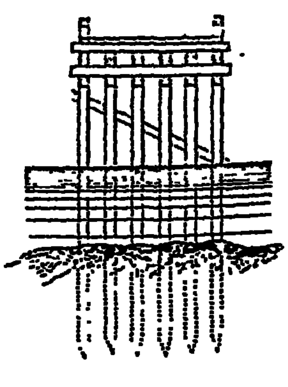

Fig. 101a.

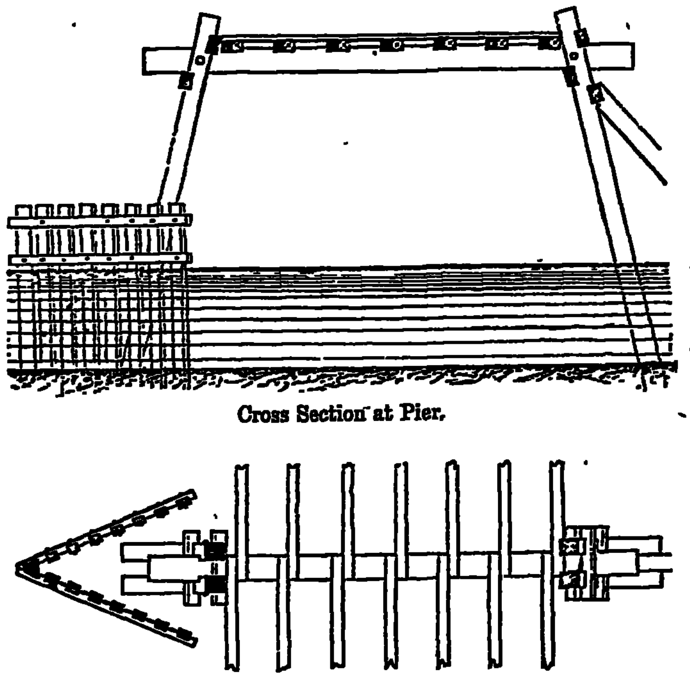
§ 73. *Bridges built before the year* 1000 A.D.—Herodotus mentions a bridge erected by Nitocris over the Euphrates at Babylon. It appears to have consisted of stone piers connected by planking, which was removed at night. The river was diverted to allow the piers to be built. Diodorus Siculus ascribes the work to Semiramis.

The first bridge constructed at Rome was called the *Pons Sublicius*, or wooden bridge (*sublica* meaning a stake or Sublician
pile). It is said to have been built by Ancus Martius, and Bridge.
rebuilt by the chief priests, who from this circumstance were called "Pontifices." Fig. 101 shows the design of this bridge as restored by Colonel Emy (*Traité de l'art*

de la charpenterie) from the descriptions given in the historians. This was the bridge defended by Horatius Cocles.



Cross Section at Pier.

Plan at Pier.

FIG. 102.—Bridge thrown across the Rhine by Julius Cæsar.

Fig. 102, also taken from the work of Colonel Emy, is intended to represent the design of the bridge thrown across the Rhine in ten days by Julius Cæsar (*De Bell. Gall.* iv. 17).

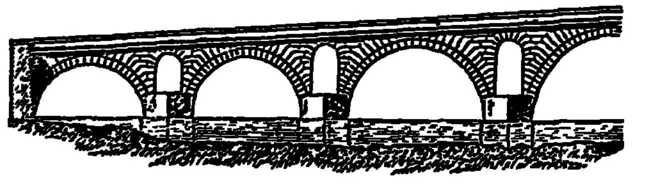


FIG. 103.—Pons Milvius.

The *Pons Milvius* (fig. 103), now Ponte Molle, was built a mile and a half from Rome by the Censor Ælius Scaurus, about 100 B.C. Some part of the first bridge is supposed to remain, although it has been altered from time to time. The arches vary in their opening from 51 feet to 79 feet 9 inches; the waterway between the piers is 413 feet 3 inches; the breadth of the bridge, 28 feet 9 inches; these dimensions are given on the authority of Cresy (*Encyclopædia of Civil Engineering*). The following bridges also crossed the Tiber at Rome:—The *Pons Palatinus*, which stood on the site of the present Ponte Rotto; the *Pons Fabricius* and *Pons Cestius*, which still remain; the *Pons Janiculanus*, which occupied the site of the modern Ponte Sisto; the *Pons Vaticanus*, which has disappeared; and the *Pons Ælius*, built by Hadrian (13 A.D.), now the bridge of St Angelo. This bridge (fig. 104) was repaired by Popes Nicholas III. and Clement IX. The largest arch has a span of 62 feet 4 inches, and the width of the bridge is 50 feet 9 inches.

Pons Milvius

Other Roman bridges.

The bridge erected by Trajan (104 A.D.) across the Danube, just below the rapids of the Iron Gate, has been the subject of much controversy. The drawing (fig. 105) was originally taken from a bas-relief on the Trajan column at Rome. A description of the bridge is given by the ancient historian Dion Cassius, who states that the bridge had twenty piers of hewn stone, 150 feet high and 60 feet wide, with openings between them of 170 feet, spanned by arches. Doubt has been thrown on the accuracy of this description, because the design shown in fig. 105 is obviously unsuited to a span of 170 feet; nevertheless thirteen piers are still visible out of the twenty, according to Murray's *Handbook*. The writer has not been able to find any accurate measurement of the width between these piers, but as the *Handbook* speaks of the length of the bridge as perhaps 3900 feet, and as the Conte Marsigli, writing from personal observation, in a letter to Montfaucon, gives the total length as probably 3010 feet, there can be no doubt that the spans were very considerable, and that the representation of the design in the bas-relief is almost wholly conventional. The one point as to which it gives clear information, not supplied elsewhere, is that the superstructure was of wood. The piers seem to have been founded by sinking caissons. Murray's *Handbook* gives the depth of the river as 18 feet. Apollodorus of Damascus was the architect of this remarkable bridge. The bridge at Rimini, built during the reign of Augustus, was especially admired by Palladio (Rondelet, *L'Art de bâtir*). The bridge at Narni, on the road from Loretto to Rome, also built by Augustus (Montfaucon), and the bridge of Alcantara over the Tagus, built in the reign of the Emperor Trajan, are often cited as remarkable works.

The Romans frequently adorned their bridges with a triumphal arch. A small example of this kind of bridge at St Chamas, in France, is shown in fig. 106 (Cresy's *Encyclopædia of Civil Engineering*). The span of the arch is 42 feet, and the voussoirs are 3 feet 5 inches deep. Fig. 107 shows the bridge of Narses, built in the 6th century, and which carried the Via Salaria across the Anio or

Ponte Salaro.

Teverone. This bridge was blown up during the panic caused by the approach of Garibaldi to Rome in 1867.

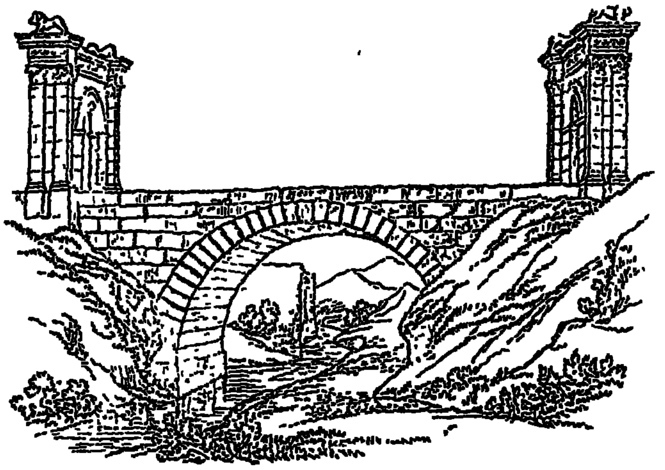

FIG. 106.—Bridge at St Chamas.

We see here, perhaps, one of the earliest examples of the castle built to protect the bridge against an enemy or to enforce payment of a toll,—the bridge and castle of mediæval romance.

§ 74. 1000 to 1300 A.D.—A very bold arch over the Serchio near Lucca is shown in plate 58 of Hann and Hosking's treatise, with the approximate date of 1000 A.D., but the authority for this date is not given. The span of the arch is 120 feet, and the roadway, which stands at a height of more than 60 feet above the water level, is only 9 feet wide; in fact the arch is little more than a broad wall. Owing chiefly to the excellence of the mortar employed, this arch withstood a flood which rose nearly 30 feet above the springing of the arch. This structure is one of the many "Devil's Bridges."

In the year 1178 a famous bridge was begun over the

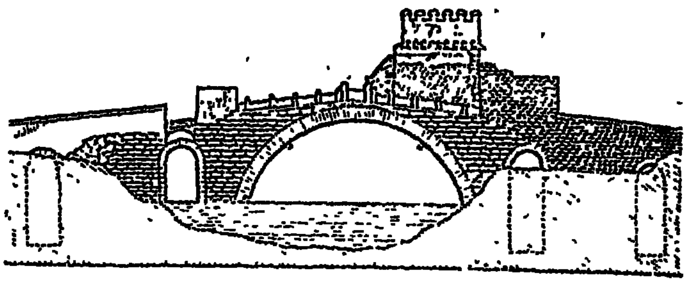

FIG. 107.—Ponte Salaro.

Rhone at Avignon by Saint Benezet, the head of one of certain religious confraternities, which undertook the building or repair of bridges during the Middle Ages, and were called Fratres Pontis or Hospitalarii Pontifices. The bridge was finished in 1188. Four arches still remain, and are remarkable in having an elliptical outline with the radius of curvature smaller at the crown than at the haunch, a form which accords more truly with the linear equilibrated arch than the modern flat ellipse with the largest radius at the crown. A description and drawing of this remarkable bridge will be found in the *Dictionnaire raisonnée d'Architecture* of M. Viollet-le-Duc.

A religious confraternity, founded in the first instance by a certain Mary, the maiden daughter of a ferryman, is said to have built a timber bridge near the site of the

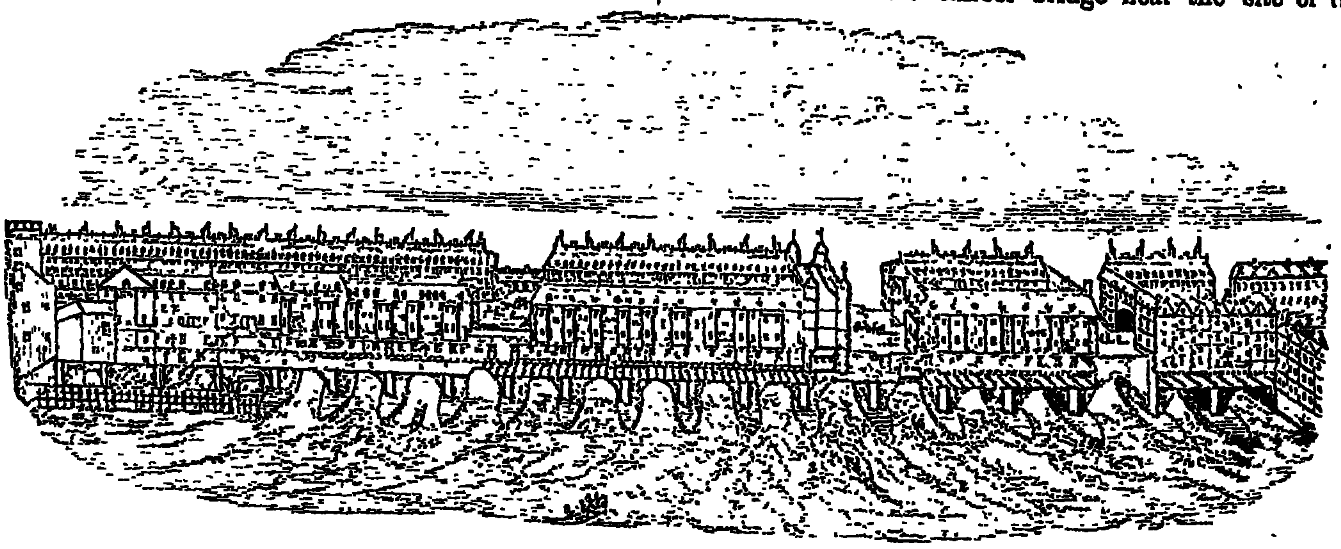

Fig. 108.—Old London Bridge, A.D. 1700.

present London Bridge, but it seems quite uncertain when the first bridge over the Thames was built. There is little doubt, however, that it was of timber, and had frequently to be reconstructed. Stow, in his *Survey of the Cities of London and Westminster*, gives a description of the building of the first stone structure, commonly called Old London Bridge, Plate XVIII. fig. 1.[1]

Heavy repairs were frequently necessary, and the timber houses built on the bridge were often burnt down; yet the main structure appears to have remained unaltered until the beginning of this century. It does not seem improbable that Peter of Colechurch and Saint Benezet may have been in communication with one another, both being heads of religious bodies engaged in similar works at the same time. Their letters to one another would interest engineers. A French brother Isembert, from Saintes, succeeded Peter as engineer for London Bridge.

Stow describes the partial rebuilding of the timber houses in 1645:—

"The building was of timber, very substantial and beautiful, for

[1] About the year 1176 the stone bridge over the river Thames at London was begun to be founded by the foresaid Peter of Colechurch (priest and chaplain before), "near unto the bridge of timber, but somewhat towards the west, for I read that Botolph's wharf was in the Conqueror's time at the head of London Bridge. The king assisted this work, a cardinal then being legate here; and Richard, archbishop of Canterbury, gave one thousand marks towards the foundation. The course of the river for the time was turned another way about by a trench cast for that purpose, beginning, as is supposed, east about Rotherhithe, and ending in the west about St Patricksey, now termed Battersea. This work, to wit the arches, the chapel, and stone bridge over the Thames at London, having been thirty-three years in building, was, in the year 1209, finished by these worthy merchants of London—Serle Mercer, William Almaine, and Benedick Botewrite, principal masters of work; for Peter of Colechurch deceased four years before the work was finished, and was buried in the chapel builded on the same bridge in the year 1205."

the houses were three stories high, besides the cellars, which were within and between the peers, and over the houses were stately platforms leaded with rails and ballasters about them, very commodious and pleasant for walking and enjoying so fine a prospect up and down the river, and some had pretty little gardens with arbours."

The passage between the houses was made 20 feet; previously it had been but 14 feet, and in some parts 12 feet. These beautiful houses were burned in 1666, when they were replaced by a still finer pile of buildings, with a *uniform roadway of 20 feet in width. Fig. 108 shows* the bridge as it appeared in 1700.

The piers varied in thickness from 25 to 34 feet, and were raised on strong elm-piles, covered with thick planks bolted together. The openings in the arches varied from 10 feet to 32 feet 9 inches. The whole waterway was 336 feet 9 inches, two-thirds of the stream being occupied by piers.

FIG. 109.—Croyland Bridge.

§ 75. 1300 to 1700 A.D.—The strange triangular bridge
land. at Croyland (fig. 109) is another example of a bridge probably built for or by a religious body. This structure stands at the confluence of the Welland, the Nyne, and the Catwater drain; three pointed arches, having their abutments at the angles of an equilateral triangle, meet in the middle, giving three watercourses and three roadways. Each arch has three stone ribs, and the nine meet in the centre. Croyland "triangular bridge" is alluded to in a charter of the year 943; from the character of the masonry the present structure is supposed to have been built in the
m. beginning of the 14th century. A bridge over the Trent at Burton, 1534 feet in length, and consisting of 34 arches, was also built by a religious community under Abbot Bernard.

es. Fig. 110 shows the old bridge at Saintes as M. Viollet-le-Duc considers that it appeared towards the end of the 14th century. The following description is abridged from his *Dictionnaire raisonnée d'Architecture*:—

"The first gate appeared on the right shore of the river, on the side of the Faubourg des Dames; next came the Roman arch, the upper part of which was crenelated during the Middle Ages; next on the side of the town stood a tower of oval plan, through which the road lay; the town gates with flanking towers closed the end of the bridge. From the first gate to the Roman arch the bridge was of wood, as was also the case between the great tower and the town gates, so that by the removal of this part of the roadway all communication could be cut off between the town and the tower as well as between the bridge and the Faubourg; moreover, the parapets were crenelated, so that the garrison of the town could at will stop all navigation."

Clearly it was quite as important in those days to be able to arrest as to facilitate communication between the two sides of the river.

The architects of the Renaissance showed great boldness
o. and originality in their designs. The largest arch known to have been built spanned the Adda at Trezzo, constructed by order of Bernabò Visconti, duke of Milan (latter half of 14th century. This bridge is described in Haun and Hosking's *Bridges* as having consisted of "a single arch of

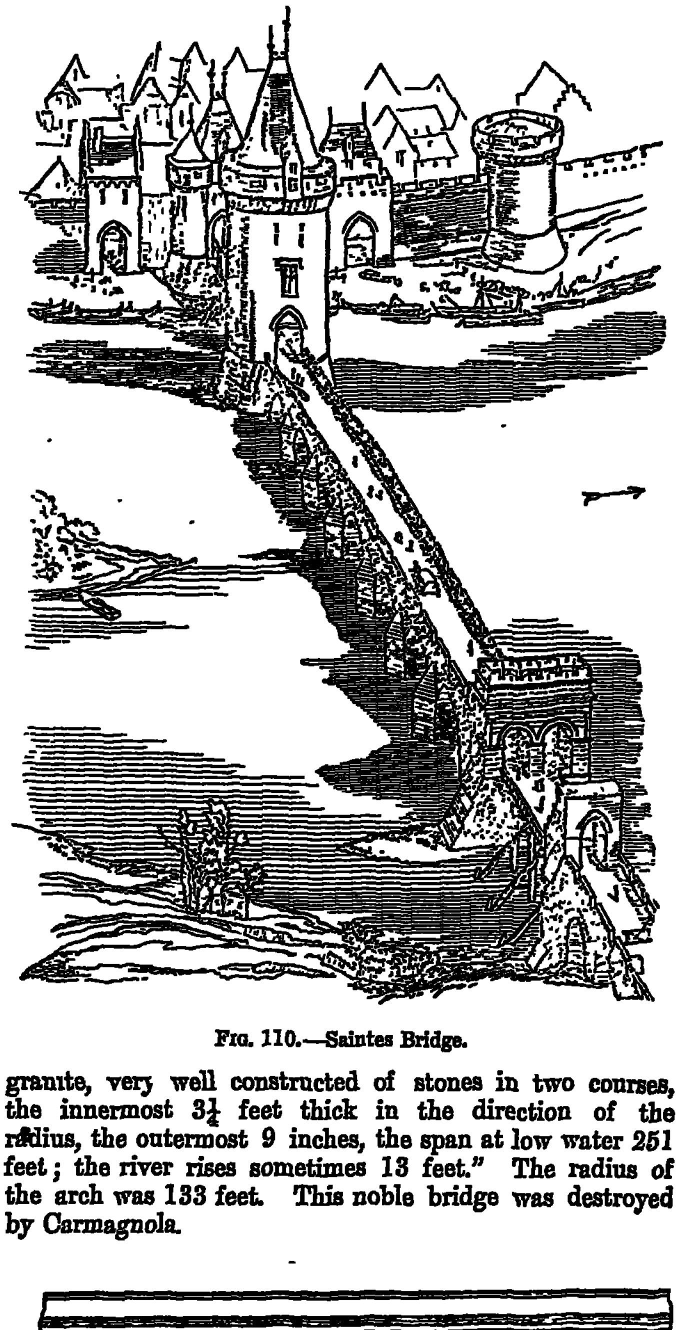

FIG. 110.—Saintes Bridge.

granite, very well constructed of stones in two courses, the innermost $3\frac{1}{4}$ feet thick in the direction of the radius, the outermost 9 inches, the span at low water 251 feet; the river rises sometimes 13 feet." The radius of the arch was 133 feet. This noble bridge was destroyed by Carmagnola.

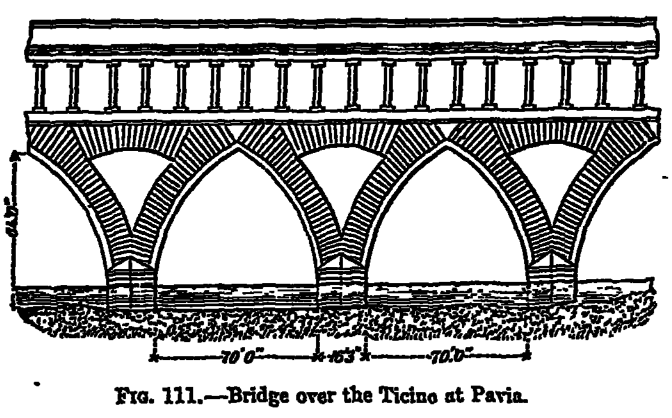

FIG. 111.—Bridge over the Ticino at Pavia.

The covered bridge over the Ticino at Pavia (fig. 111) Pavia.
was erected, under Gian Galeazzo Visconti, about the end of the 14th century. This bridge, which still exists, has seven pointed brick arches, each 70 feet in span and 64 feet in height; the depth of the arch ring at the crown is 5 feet 6 inches. The tympanum is pierced; the bricks used in

the arches are formed to suit their position, and are hollow

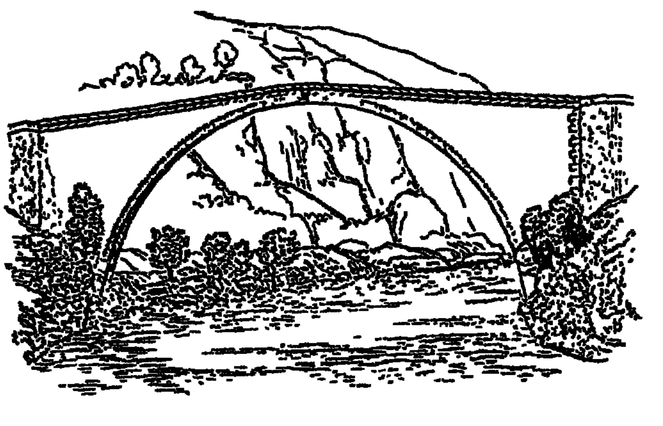

FIG. 112.—Bridge of Brioude.

in the middle to diminish the weight. The roof of the roadway is carried by 100 rough granite columns.

Brioude. Fig. 112 taken from Montfaucon's *Antiquité expliquée*, shows the old bridge of Brioude across the Allier in France. Montfaucon and Séguin speak of this as a Roman work, but Gauthey gives the date 1454 for its construction, and names Grenier and Estone as builders without giving his authority. The design of the bridge appears to favour the date given by Gauthey. The span was 183·73 English feet (Rennie, *Proc. I.C.E.*), the arch was a segment of a circle and the height 60 feet, while the width of the bridge was only 16 feet. This bridge fell in 1822.

Rialto, Venice. The bridge of the Rialto at Venice (fig. 113) was begun in 1588, Antonio da Ponte being the architect. The span of the arch is 91 feet, the height above the water level 24 feet 6 inches, and the width of the footway 72 feet. Erroneous statements are often met with that this bridge was built from a design by Michel Angelo; the mistake has arisen from the misinterpretation of a passage in the works of Vasari. Rondelet, in his *Essai Historique sur le Pont du Rialto*, gives a full account of the rival

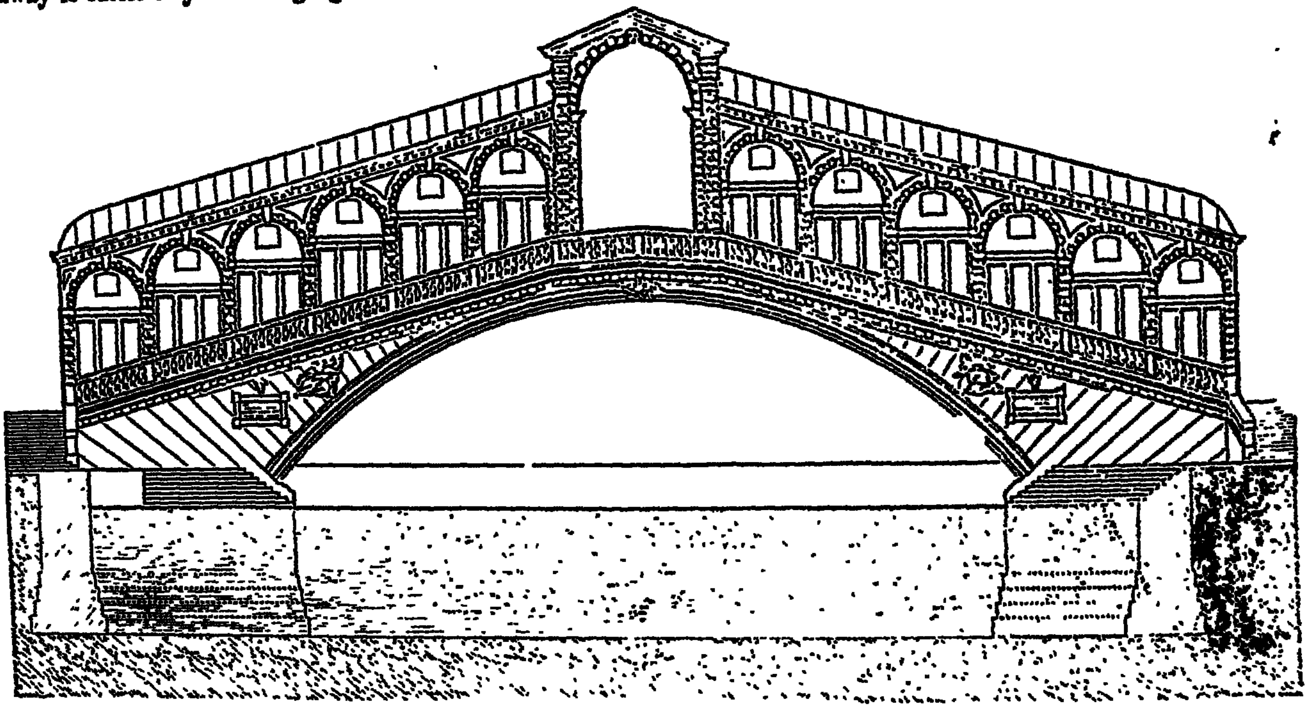

FIG. 113.—Bridge of the Rialto, Venice.

designs submitted to the senate by Antonio da Ponte and Palladio.

Florence. Ponte della Trinità. Fig. 114 shows the singularly beautiful "Ponte della Trinità," erected at Florence (1566) from the designs of Ammanati. Those who are curious in such matters may observe with interest the amended design for this bridge, given in Hosking's *Architectural Treatise on Bridge Building*, p. 241, which serves to show how easily a noble design may be spoilt by an alteration in the proportions of its parts.

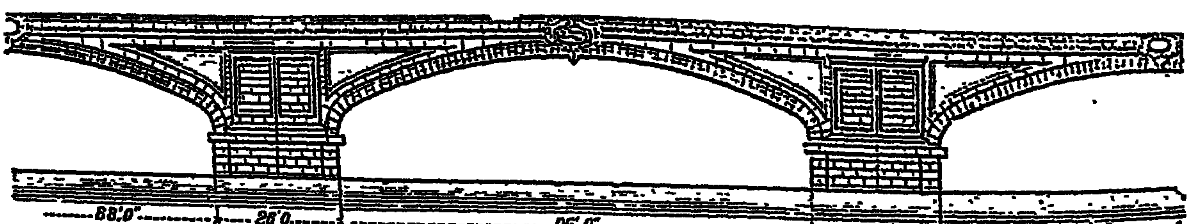

FIG. 114.—Ponte della Trinità, Florence.

York. A fine bridge over the Ouse at York, erected in the reign of Queen Elizabeth, was taken down some years ago; it is shown in fig. 115. The span of the largest arch was 81 feet (Allen), and the rise 26 feet 3 inches.

Pont Neuf, Paris. The well-known Pont Neuf at Paris was built in 1604. The design has no feature calling for special remark. Fig. 116 shows the bridge over the Conway at Llanrwst in Wales, the design for which was furnished by Inigo Jones in 1634. The middle arch has a span of 58 feet. The structure is easily set in vibration, and is known as the "shaking bridge." Further particulars concerning this and many other old English bridges will be found in Smiles's *Lives of the Engineers*, chap. iii. vol. ii., edition 1874.

Llanrwst.

Ispahan. A bridge over the Senderud at Ispahan is described as follows in Heck's *Iconographic Encyclopædia*, with illustrations:—"It (the bridge) is 2250 feet long, 120 feet high, and 156 feet broad; the middle way is 60 feet broad, and the sideways are paved with marble, and the latter lead through arcades, to which the ascent is by stairs

in the four towers of the bridge. The bridge has 29

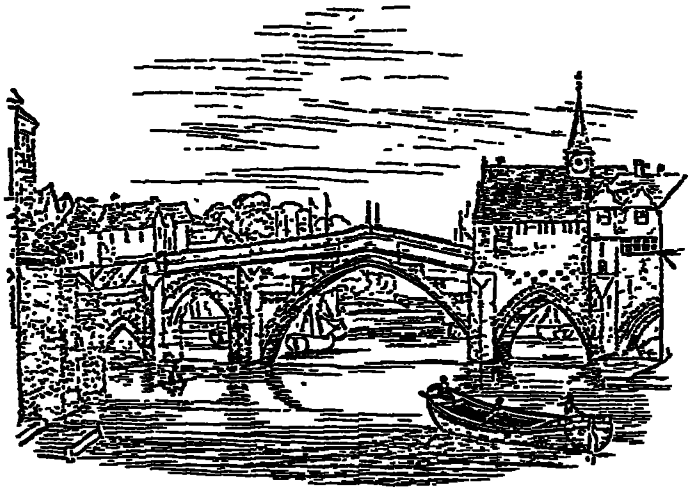

FIG. 115.—Old Bridge at York.

arches of 50 feet span, and the pillars are 25 feet thick.' In the illustration the arches are Moorish, and the covered sideways lofty, with 3 arches of small span over each main arch of the bridge. The design is remarkably fine. Heck calls it the bridge of Barbaruh, and states that it is named from its builder, but it is of unknown antiquity. All the bridges of Ispahan are said, in the 7th edition of the present work, to have been built under Shah Abbas I. (1585 to 1628).

Heck mentions a bridge at Loyang in China, said to have a length of 26,800 feet, and another at Focheu 22,000 feet long, both from 60 to 70 feet wide.

West-ster Black-rs dges.

§ 76. 1700 to 1817.—Old Westminster Bridge (Labelye) and Old Blackfriars Bridge (Mylne), both of which have now been removed, were built in the middle of the 18th century. Their failure after so short a period was due to a defective system of foundation and to the increased scour caused by the removal of old London Bridge.

it-y-tu ydd.

The Pont-y-tu-Prydd over the River Taff near Newbridge is shown in fig. 117. The arch measures 140 feet between the abutments, and has a rise or versed sine of 35 feet. The width of the soffit is 15 feet 10 inches at the springing, diminishing to 14 feet 5 inches at the crown by six offsets on each face. The roadway is 11 feet wide over the centre

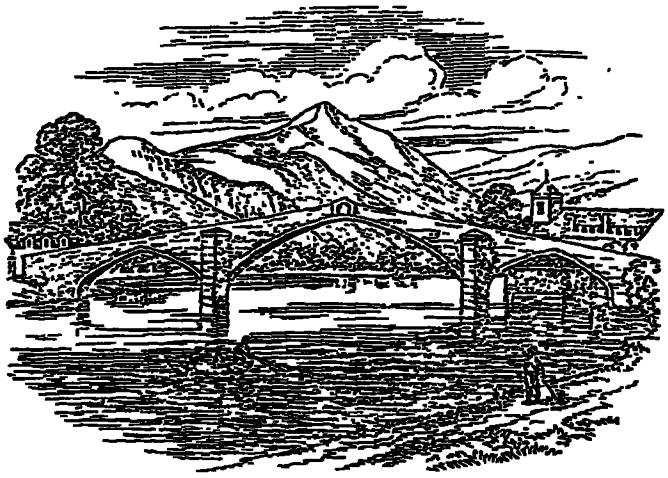

FIG. 116.—Llanrwst Bridge, Wales.

of the arch. The arch stones on the face are 2 feet 6 inches

FIG. 117.—Pont-y-tu-Prydd.

deep, the rest of the ring being rubble masonry. This

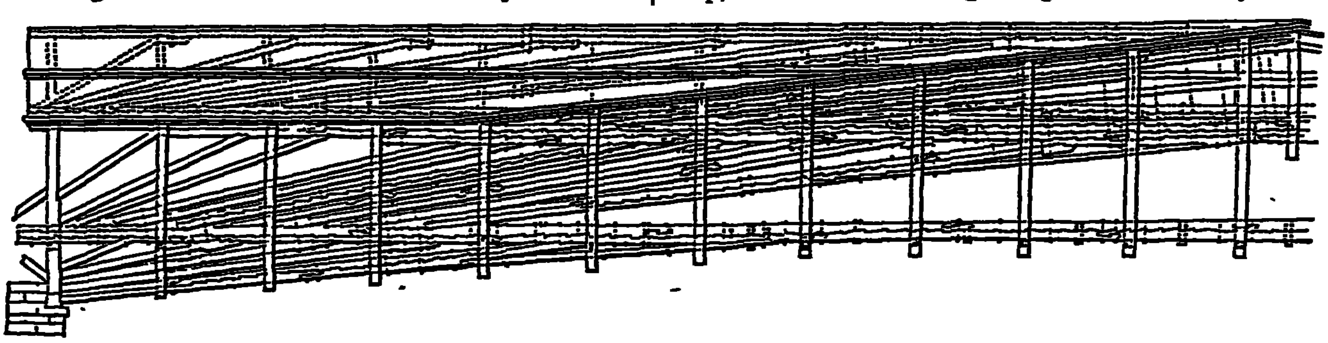

FIG. 118.—Half Truss of Wittingen Bridge.

bridge was built by William Edwards, a self-educated country mason. It was completed in 1750 after the failure

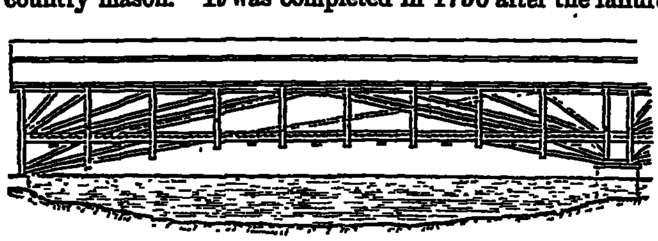

FIG. 119.—First Arch of Schaffhausen Bridge.

of a similar structure, in which the weight of the haunches was excessive and forced up the crown, the depth of which was very small. This failure led to the adoption of the pierced spandrils.

Fig. 118 shows half of the truss for the bridge of Wittingen, built in 1758 by the brothers Grubenmann, probably the finest specimen of a wooden bridge that has ever been constructed; the design might be analyzed as consisting of a series of superposed trusses, as in fig. 87, which represents the bridge at Schaffhausen built by the same engineers or village carpenters. The Schaffhausen bridge (fig. 119), destroyed by French troops in 1799, had two openings, one of 172 feet and the other 193 feet. The Wittingen bridge, burnt shortly afterwards, had a span

Wittingen

Schaff-hausen.

of 390 feet, being the largest opening ever spanned by wood.

Mr Smiles states that the first attempt to build a cast-iron bridge was made in 1755 at Lyons, and that one of

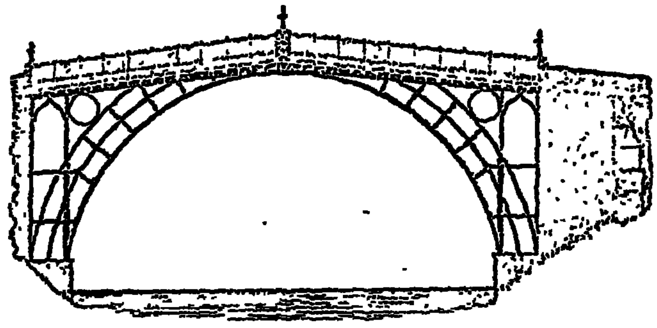

Fig. 120.—Coalbrookdale Bridge.

the arches was put together in a builder's yard, but that the project was abandoned as too costly. Mr Abraham Darby, the owner of iron-works of Coalbrookdale, was the first person who actually erected a cast-iron arch. This bridge (fig. 120) crosses the Severn by a span of 100 feet, near the town of Ironbridge, which has sprung up in the neighbourhood. Each of the ribs consisted of two pieces. The design is a bold and original one, and has been practically successful. Wearmouth Bridge, completed in 1796, is an arch built of open cast-iron panels, acting as voussoirs; the span is 236 feet, with a rise of 34 feet; the springings begin 95 feet above the bed of the river; and the width of the bridge was 32 feet. It contained 214 tons of cast-iron and 46 tons of wrought iron. The name of Thomas Paine, the well-known author, has been associated with the design of this bridge; but Mr L. D. B. Gordon (first Professor of Engineering in Glasgow) assures the writer that after careful investigation he finds that Rowland Burdon, member for the county, was engineer, architect, and paymaster for this remarkable bridge. It was repaired and widened by Robert Stephenson in 1858. The bridge erected by Coalbrookdale.

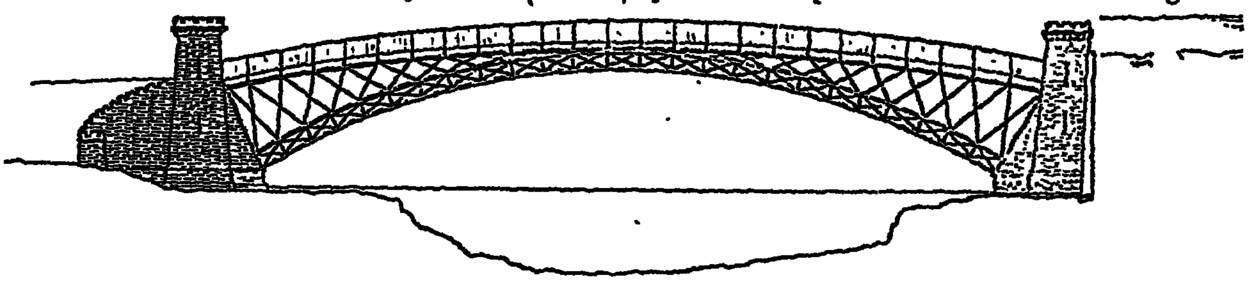

Fig. 121.—Cast-Iron Bridge at Craigellachie.

Telford at Craigellachie (fig. 121), over the Spey, in the beginning of this century, shows a great advance in the conception of what was the safest form in which to apply cast-iron to an arch.

§ 77. 1817 to 1845.—*London Bridge and Waterloo Bridge.*—London new bridge (fig. 40, *supra*, and Plate XVIII. fig. 2), is as fine an example of the modern stone arch bridge as can be found. The shape of the arches, the variation in their span, the slight curvature of the roadway, and the simple yet bold architectural details, are combined so as to produce a singularly beautiful structure. It is now insufficiently wide for the traffic it has to convey, but all who value beauty must earnestly desire that it may not be disfigured by having overhanging footpaths fitted to it as has been frequently proposed. London can well afford to pay for new bridges, but can by no means afford to part with a single object of real beauty.

The design was made by Mr George Rennie, and the acting engineer was his brother, Sir John Rennie. The centre arch has a span of 152 feet, and rises 29 feet 6 inches above Trinity high water mark; the arches on each side of the centre have a span of 140 feet, and the abutment arches 130 feet. The total length of the bridge is 1005 feet, its width from outside to outside 56 feet, and height above low water 60 feet. The two centre piers are 24 feet thick, the exterior stones are granite, the interior, half Bramley Fall and half from Painshaw, Derbyshire.

The voussoirs of the centre arch (all of granite) are 4 feet 9 inches deep at the crown, and increase to not less than 9 feet at the springing. The general depth at which the foundations are laid is about 29 feet 6 inches below low water. Seven years and a quarter were spent in the construction of London bridge, which was opened in 1831. The total cost was £1,458,311, but the contractor's tender for the bridge alone was £425,081.

Waterloo Bridge, Plate XVIII. fig. 3, is another fine structure of the same character (1817).

Introduction of Suspension Bridges.—It will be observed that from the earliest ages in which we have records of the construction of permanent bridges until very lately, the stone or brick arch has been the structure principally relied on. Timber bridges more or less permanent have also been employed for great spans, as in the noble bridges erected by the brothers Grubenmann (1757); and after the construction of the bridge at Coalbrookdale (1777) cast-iron was not unfrequently employed in England. The theory of the metal arch was, however, very imperfectly understood, and the great metal arch of Southwark bridge (completed 1819), Plate XVIII. fig. 4 (largest span 240 feet), is little more than a heavy and wasteful imitation of a stone ring. By the use of timber or cast-iron instead of stone, the opening which a bridge could span was, however, somewhat increased. An immense stride in this direction was made when suspension bridges were introduced. A bridge of this kind over the Tees, 70 feet in length, was built in 1741 for the use of miners. Similar bridges are also said to have been used by Mr Finley in America, but the introduction of the modern suspension bridge practically dates from about 1820. (Galashiels bridge, 112 feet in length, was constructed in 1816, also a bridge of similar dimensions at Peebles over the Tweed). In 1819 Telford began the construction of the Menai suspension bridge (Plate XIX. fig. 2), in which the span of the catenary is 570 feet and the dip 43 feet. The success of this structure led to the construction of many other large suspension bridges, as at Fribourg (span 870 feet), Hammersmith (span 422 feet), Pesth (span 666 feet). This form of bridge was not, however, found suitable for railway traffic; and on the introduction of railways engineers were for many years dependent on stone, brick, or cast-iron arches.

tions, experiments and calculations on the strength and best form of tubes were made by Mr William Fairbairn (Sir William Fairbairn) and Mr Eaton Hodgkinson. In the course of the experiments it was found that the tube could be made self-supporting over the desired span of 460 feet; and in consequence of this discovery the Conway and Menai tubular bridges were built, being the first great examples of properly designed girders. Some disputes arose as to the real inventor of these bridges. Sir William Fairbairn justly claimed the great merit of first perceiving that the girder might be self-supporting. Mr Hodgkinson had, perhaps, the smallest part in the design, but the shares of Fairbairn and Stephenson respectively cannot be very rigorously apportioned; nor is this now of much consequence.

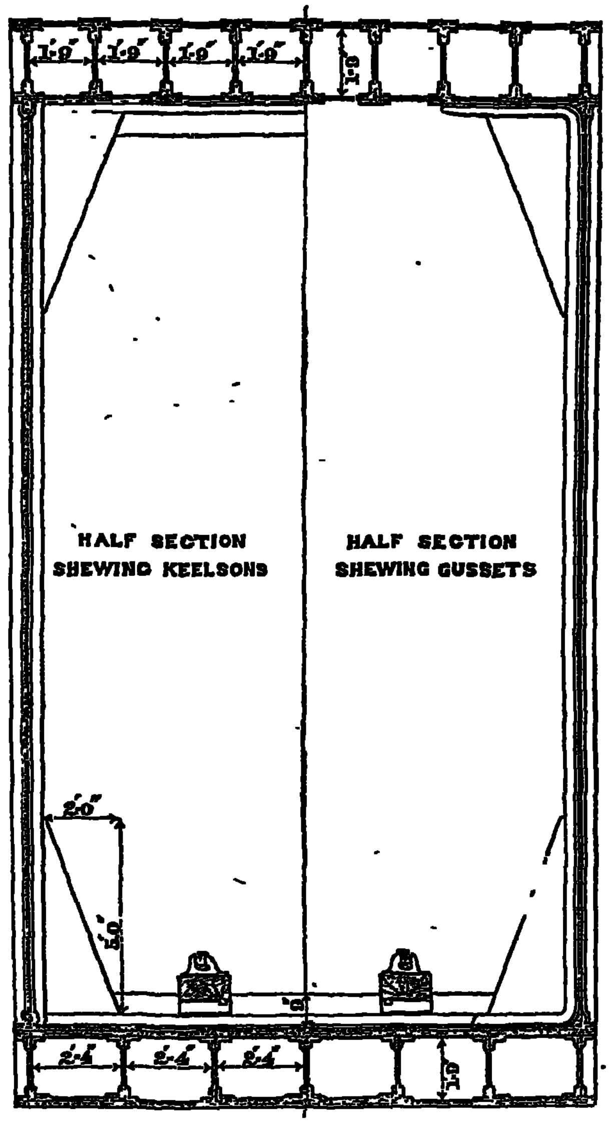

FIG. 122.—Britannia Bridge (Cross Section of Tubular Girder).

Both engineers were men of extraordinary merit, and co-operated in producing the great revolution in practice which has led to the adoption of the wrought iron girder as the most common type of bridge. The first train passed through the Britannia Bridge in 1850. The following description of the structure appeared in the 8th edition of the present work. It will be seen that this description is to some extent a defence of the design against criticisms asserting that the structure was unnecessarily heavy and costly. It is true that a considerably lighter bridge could now be built, but some prudence in introducing so great a novelty was certainly commendable.

"The Britannia Bridge which carries the Chester and Holyhead Railway over the Menai Straits (figs. 122 and 123, and Plate XIX. fig. 1) consists of two independent continuous wrought iron tubular beams, 1511 feet in length, and weighing 4680 tons each, independent of the cast-iron frames inserted at their bearings on the towers. They are 15 feet wide, and vary in depth from 23 feet at the ends to 30 feet at the centre. They rest on two abutments and three towers of masonry at a height of 100 feet above high water. The roadway is laid along the bottom, viz., one line of rails in each tube. The centre or Britannia tower, which is altogether 230 feet high, is built on a rock in the middle of the Straits. The bridge has thus four spans, viz., two spans of 460 feet over the water, and two spans of 230 feet over the land. On each side the weight of a single span of 470 feet is 1587 tons, and of a span of 242 feet 630 tons. These tubes repose solidly on the centre tower, but repose on roller beds on the land towers and abutments. Now, these gigantic dimensions are by no means the only remarkable features in this work. The opponents of the Holyhead Road had imposed conditions on the Chester and Holyhead Railway which were thought insurmountable with respect to this bridge. The navigation was not to be interrupted—no scaffolding could thus be used—and the clear height of 100 feet was to be retained throughout,—

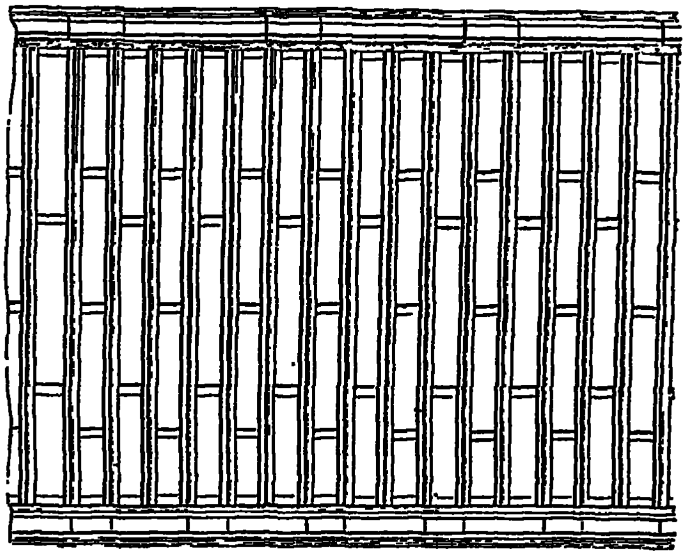

FIG. 123.—Britannia Bridge (Part Elevation of Tubular Girder).

arches being objected to unless the springing and not the centre was at this elevation. The tides set through this portion of the Strait with a velocity of 9 miles per hour, and the quiet water at each turn of the tide lasts but for a very short space of time. The tubes were designed to meet all these requirements; they were so constructed at a considerable distance from their permanent site on the shores of the Straits; they were floated upon pontoons upon these rapid tides to the base of the towers; and they were then drawn up by hydraulic presses to their required height. They were here united through the towers by the insertion of shorter lengths, and ultimately brought into the condition of continuous beams as regards strain, by the means employed for their junction. It is evident such structures would be designed specially for such varied circumstances, for example:—

"As soon as they were completed on temporary platforms, these platforms were removed, and they became isolated beams; the ends were accordingly strengthened with cast and wrought iron framing for this special object, and had they always remained there the sides might have been throughout considerably lighter than they are; they now weigh nearly 40 per cent. of the whole weight. But in the next operation, that of floating, the tubes were liable to be supported at *any point* of their length, besides being subjected to chances of considerable distortion, and to disasters

which on more than one occasion did actually threaten their entire destruction. The stiffening frames and gussets, which in an ordinary girder would have only been necessary at the ends, became therefore necessary throughout the whole length, and even the top and bottom were considerably modified, as it is evident that while overhanging the pontoons on each end to the extent of 70 feet, the top, instead of being in compression was thrown into extension; the weight of the tubes was consequently much increased by these arrangements. Again, they had to be raised by being suspended freely from four chains. Provision for this suspension from such limited attachment had also to be made of a totally opposite character from that made for their vertical support when on their bed; and, ultimately, when raised to their place, they remained no longer independent beams, but were converted into continuous beams, parts before in tension being now thrown into compression, and *vice versa;* while the ends which were before subject to no horizontal strain were now exposed to greater strain than even the centre of the span. And, last of all, during the act of raising one of these enormous masses, the press from which it was suspended burst, and one end of the beam fell through a space of no less than 9 inches on to a loose uneven heap of planks beneath it, bulging in the bottom plates, breaking all the castings, distorting seriously the sides and stiffening frames; while the broken press itself, which descended from a height of about 100 feet above, broke through the top plates and completed the crippling of the whole section of support. It may surely be doubted whether anything but a tube could have stood such unexampled violence; and in proportioning the parts of a structure destined for such usage, the mere consideration of the strain to which as an ordinary beam it would be subjected, formed but a part of the problem; no direct comparison can therefore be made between the weight of this bridge and an ordinary beam. If this were the case with the large spans, it is still more so with the small spans of 230 feet, which as simple beams would weigh only 230 tons each, whereas their actual weight is 650 tons. But it must be borne in mind that as regards the bridge itself these small spans were not required at all, and that they were merely designed and used as counterpoises for

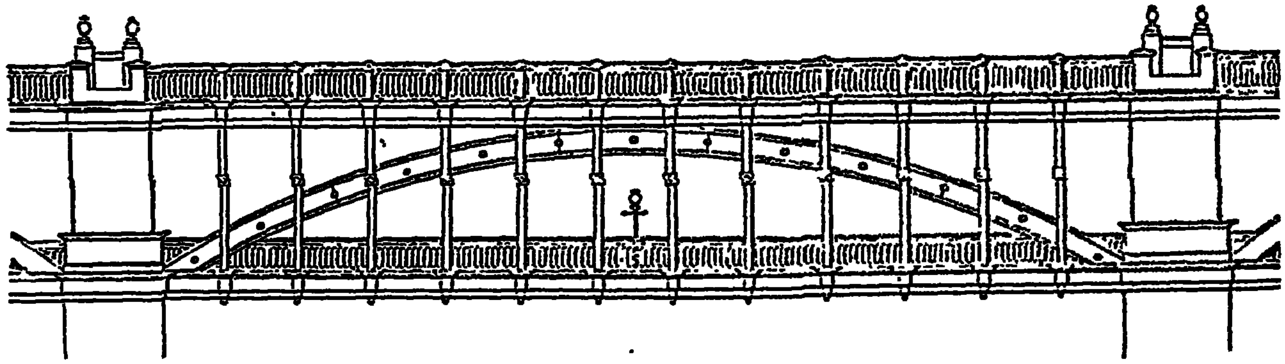

FIG. 124.—Elevation of Bowstring Arch, High-Level Bridge, Newcastle

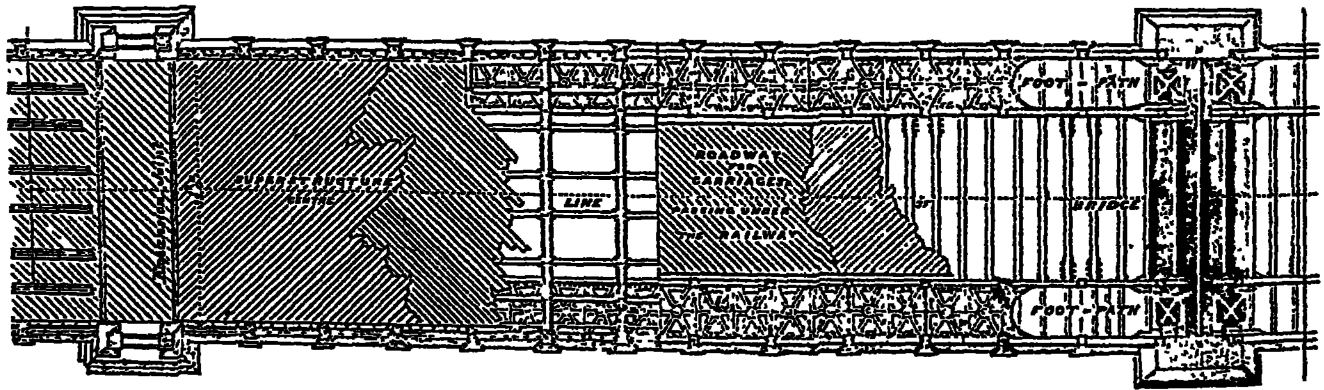

FIG. 125.—Plan of High-Level Bridge, Newcastle.

the large tubes, for the important purpose of converting them into continuous beams by their overhanging weight. By examining their detail, it will be found they are designed solely for this special purpose, their use as beams being made entirely subsidiary.

"Some misapprehension exists on the object and importance of the cells of which the top and bottom of these tubes is composed. These cells are rectangular, there being eight of them in the top and six of them in the bottom, and they run throughout the bridge. With respect to their importance, it must be observed that the whole section of the top of the Britannia tube at the centre is 648·25 square inches, and of the bottom 585·43 square inches, and that the tube is 15 feet wide; the thickness of a single plate to ensure this section would therefore have been 2·7 inches for the top, and 2·3 inches for the bottom; and had such a plate been procurable, nothing better could have been desired, and the cells would be unnecessary. Such a thing, however, is evidently impossible, and the engineer in this, as in numberless other details, had to adopt what he could obtain; now the arrangement of the plates in cells is almost the only conceivable arrangement possible for obtaining the required section, allowing access, at the same time, to every part for construction and future maintenance. This alone led to their use in the bottom of the tube, where their form was totally unimportant. With respect to the top, however, it was of great importance, since thick plates could not be had, to ascertain the best form of cell for resistance to compression that could be devised with thin plates. A series of valuable experiments by Mr Eaton Hodgkinson led to the use of the rectangular cells as actually used, not because such form presented any peculiar advantage over any other form, as some have imagined, but because these experiments demonstrated that cells of that magnitude and thickness were independent of form, and are crushed only by the actual crushing of the iron itself; under these circumstances, the square cells were used as the best practical method of obtaining the sectional area required.

"Similar misapprehension also exists as to the considerations which led to the rectangular form of the tubes

themselves. Now, the result of direct experiments made with round, oval, and rectangular tubes—there being precisely the same section and weight in all three, and, consequently, different depths—was, that the circular tube was the weakest, and the oval tube the strongest, the rectangular form being intermediate. The oval tube was, indeed, first studied with a view to its use. Its form, however, was not favourable,—neither for its actual construction, nor for its connection with the suspension chains which were

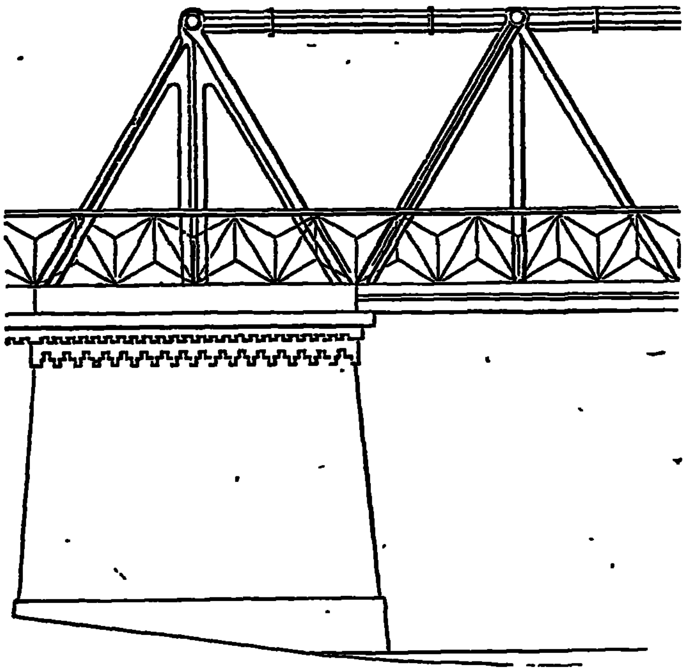

FIG. 126.—Newark Dyke Bridge.

originally intended to be used in the erection; and practical considerations, in this case, also compelled the use of the

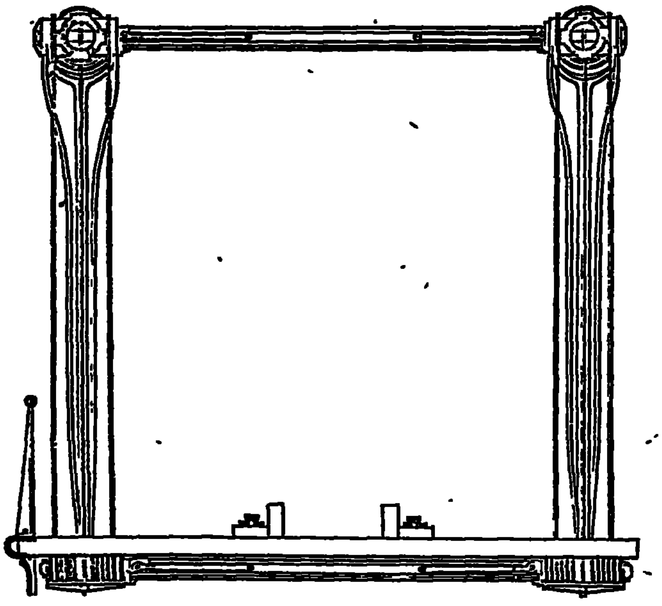

FIG. 127.—Section of Newark Dyke Bridge.

rectangular tube. It must also be remarked, that the result of experiments made on round, oval, and rectangular wrought iron tubes, when reduced to the same depth and compared, was in favour of the rectangular form, although within ordinary limits the form was not proved to be a matter of very great importance. It may be added, that this bridge has now been in use six years, that the deflection has been carefully tested, from time to time, with the utmost precision, and that not the slightest perceptible increase has taken place during that period. The care with which the painting has been attended, and the protection afforded by the roof, have also entirely preserved it from the slightest damage by oxidation; and it is difficult to conceive that even the lapse of centuries can in any way affect such a structure, or to doubt that it will remain one of the most durable, as it certainly is one of the most remarkable monuments of the enterprise of the present century."

§ 79. *Newcastle High-Level Bridge. Newark Dyke Bridge. Crumlin Viaduct.*—The High-Level Bridge at Newcastle (figs. 124 and 125, also Plate XIX. fig. 3) is a fine example of the true bowstring arch, in which there is no cross bracing. This bridge is also described at great length in the 8th edition; but the type cannot be recommended for imitation, being essentially more expensive and heavier than a true girder. The bridge was opened by the Queen in 1849. The design was therefore made almost at the same time as that for the Britannia Bridge, and is chiefly interesting as showing a transitional form intermediate between the arch and beam. The bridge has six spans, each of 125 feet, and the superstructure is supported on stone piers and abutments, the height to the soffit above high water being 83 feet. The arched ribs are cast-iron, and the ties wrought iron. 4728 tons of cast-iron and 321 tons of wrought iron were employed in the superstructure. There are two roadways, the carriage roadway passing under the railway. The bridge cost £243,000. Newcastle High-Level Bridge.

The solid or continuous plate girder soon led to the introduction of open frames, designed on similar principles.

Newark Dyke Bridge (the earliest example of a Warren girder bridge) carries the Great Northern line over a branch of the Trent near Newark. It was erected (1851–53) under the direction of Mr Joseph Cubitt from the designs of Mr Charles Wild. Newark Dyke Bridge.

This bridge (figs. 126 and 127) consists of four independent girders, viz., two for each line of railway. The roadway is beneath the girder. The top flange of each girder consists of a series of cast-iron pipes butting end to end; the

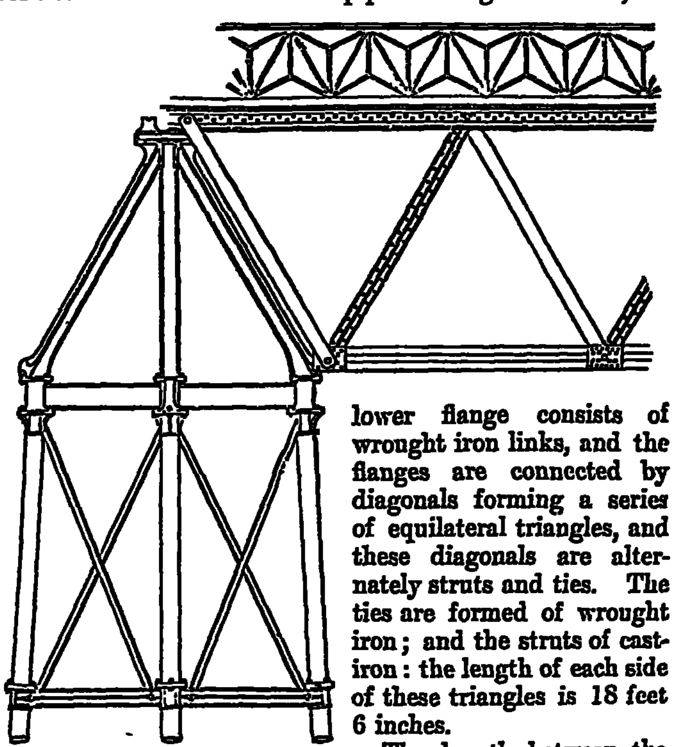

FIG. 128.—Part of Crumlin Viaduct.

lower flange consists of wrought iron links, and the flanges are connected by diagonals forming a series of equilateral triangles, and these diagonals are alternately struts and ties. The ties are formed of wrought iron; and the struts of cast-iron: the length of each side of these triangles is 18 feet 6 inches.

The length between the supports is 259 feet, and the depth from centre to centre of the joint pins is 16 feet. The clear span between the abutments is 240 feet 6 inches.

The weight of iron is 244 tons 10 cwt., of which 106 tons 5 cwt. is wrought iron, and 138 tons 5 cwt. cast-

iron, to which must be added 50 tons for the platform, making the total weight of each bridge 294 tons 10 cwt. The cost, exclusive of the masonry of the abutments, and of the permanent rails, but inclusive of the staging for fixing and the expense of testing, was £11,003.

Crumlin Viaduct. The Crumlin Viaduct, begun in 1853, and completed in 1857 (fig 4, Plate XIX.), is a fine example of the Warren girder; it was erected on the Taff Vale Extension Railway under Messrs Liddell and Gordon as engineers, by Mr T. W. Kennard as contractor. The following description is compiled from that given in Mr Humber's work:—The length of the bridge is 1800 feet, divided into two parts, one consisting of seven spans of 100 feet, and the other of three similar spans. The greatest height of the road-way above the surface of the water is not less than 200 feet. The piers are formed of cast-iron hollow columns, each 17 feet long and 1 foot in diameter; the thickness of the metal varies from 1 inch to ⅞th inch; *these columns are arranged* in tiers, each containing *fourteen columns*, the distance *between which at the base* of the pier measures 13 feet 6 inches, excepting between the centre rows, where it measures 6 feet throughout the height. The wrought iron girders are *150 feet in length* and 14 feet 6 inches deep. Some details of the construction are shown in fig. 128.

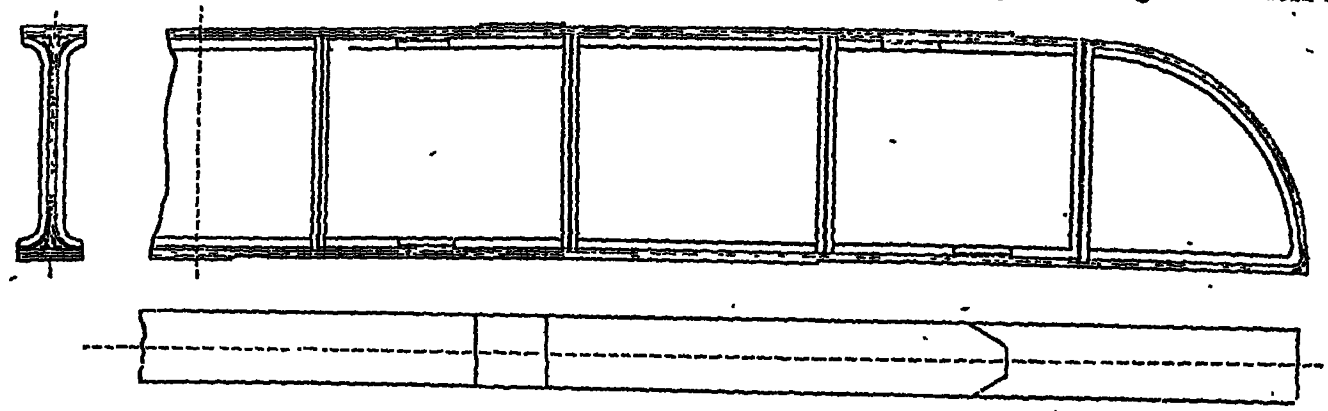

FIG. 129.—Common type of Wrought Iron Girder.

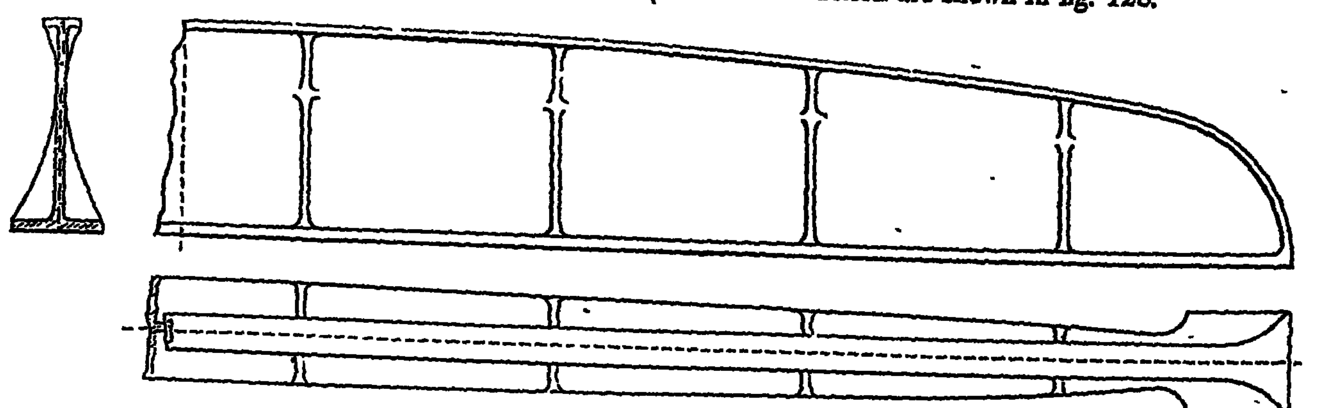

FIG. 130.—Common type of Cast-Iron Girder.

Fig. 129 shows a plan and elevation and *cross section* for half a wrought iron girder of a usual type *for small* spans. Covering plates are used to connect the *main plates* of the top and bottom webs, and stiffening angle irons are shown at the sides.

Similarly, fig. 130 shows a plan and elevation of a cast-iron girder of a usual type.

§ 80. *Niagara Suspension Bridge.*—Fig. 5, Plate XIX., shows Niagara Suspension Bridge, a structure described as follows in the 8th edition:—

"It crosses the Niagara River at a height of 245 feet above the water by a single span of 821 feet 4 inches, and forms the connecting link between the American States and Canada.

"The superstructure may be best described as a hollow rectangular box, 18 feet deep and 24 feet wide, on the top of which the railway is laid, while the bottom, which is 25 feet wide, forms the roadway for public traffic—both these floors are constructed of timber beams; and each connecting side consists of a row of double posts or uprights of timber, each pair being 5 feet apart; between them wrought iron diagonal bars are made to pass, extending each way to the fourth pair of posts at an angle of 45 degrees. The upper or railway floor is suspended from two wire cables at intervals of 5 feet, and the lower floor is suspended at similar intervals from two other wire cables which have a deflection of 10 feet more than the upper ones; these cables, four in number, are each 10 inches in diameter, and composed of seven strands, each containing 520 wires, making a total of 3640 wires. One strand forms the axis round which the other six are twisted. Sixty wires are equal to 1 square inch of solid section; therefore the total area of each cable is 60·4 square inches, or the total sectional area of iron supporting the structure is 241·6 square inches.

"Each cable rests upon a separate saddle, there being two on the top of each of the four towers. The saddles are placed on *ten cast-iron* rollers, 5 inches diameter and 25¼ inches long, which bear upon cast-iron plates 8 feet square and 2½ inches thick, strengthened by three parallel flanges which form two compartments for the reception of the saddles.

"The ends of the cables are attached to cast-iron shoes, in each of which is inserted a wrought iron pin which forms the *connection* with the anchor chains. These anchor chains are each embedded in a solid shaft of masonry 7 feet by 3 feet, enlarged at the bottom to form a chamber 8 feet square cut in the rock. The shafts are sunk to a depth of 25 feet on the New York side, and 35 feet on the Canada side.

"Each anchor chain is composed of nine links, the eight lower links being 7 feet long, and the ninth or uppermost 10 feet long. The lowest link consists of seven wrought iron bars, 7 inches by 1·4 inches each, and amounting

collectively to an area of 69 square inches. They are secured to a cast-iron anchor plate, by a pin $3\frac{1}{2}$ inches diameter. From the fourth link the chain curves, and the section is gradually increased to an area of 93 square inches. There are two towers at each end of the bridge, based upon a mass of masonry 60 feet by 20 feet, which is pierced by an arch 19 feet wide, forming the entrance to the lower roadway. The towers are 60 feet high, 15 feet square at the base, and 8 feet square at the top.

"Above the floors are 64 diagonal stays, extending from the saddles to the suspenders, amongst which they are equally distributed; they are formed of wire-rope $1\frac{3}{8}$th inches diameter. There are also 56 stays attached at their upper extremities to the soffit of the bridge, and at their other ends well anchored to the rocks below. The superstructure is thus tied down as well as suspended, and all undulations directly resisted.

"The bridge was commenced in September 1852, and opened for traffic in March 1855. The total cost was £80,000."

The use of two chains of different versed sines is certainly a defect in this design.

There are several other suspension bridges in the United States of great span, *e.g.*, Cincinnati. 1057 feet; Brooklyn 1600 feet.

§ 81. *Saltash, Victoria, and Coblentz Bridges. Fink Truss.* Salt-
—Fig. 131 shows one span of Saltash Bridge erected by

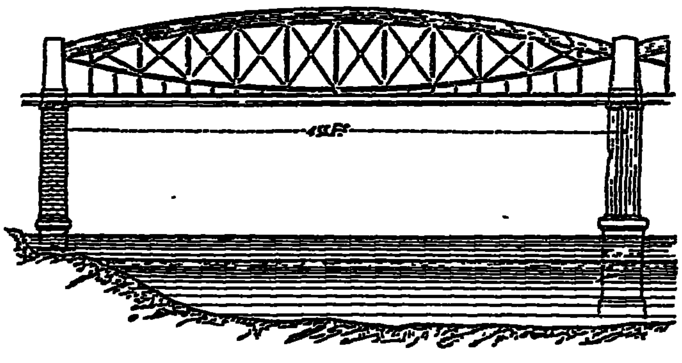

FIG. 131.—Span of Saltash Bridge.

Brunel. The span is 455 feet. The pier is a column or circular pillar of solid masonry, 35 feet diameter and 96 feet high from the rock foundation to above high-

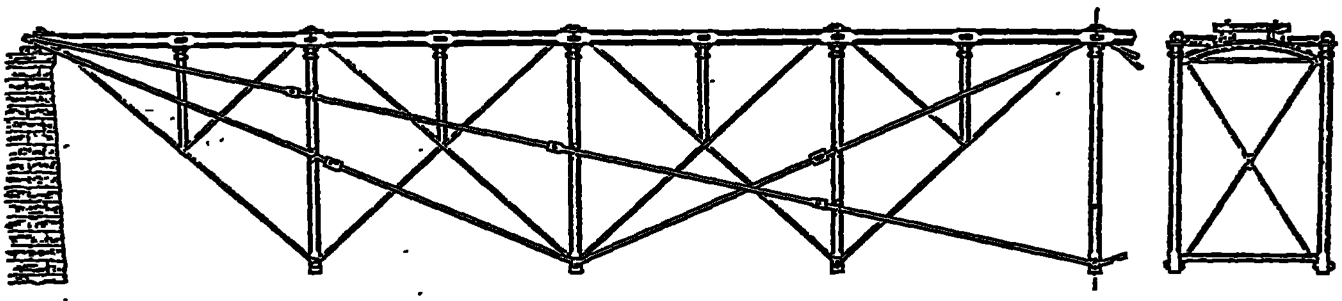

FIG. 132.—Fink Truss.

water mark. Upon this are placed four octagonal columns of cast-iron, 10 feet diameter, carried up to the level of the roadway, which is 100 feet above high-water mark.

Victoria Bridge Montreal. The Victoria Bridge over the St Lawrence at Montreal is a tubular bridge of great length (7000 feet), chiefly remarkable for its ice breakers, shown in fig. 93.

Fig. 132 shows some details of a Fink truss as used in America. The mode of computing the stresses on this truss has already been explained in § 59. All the struts are cast-iron tubes.

Fig. 133 shows one of the wrought iron arches of a Cobl
bridge over the Rhine at Coblentz. The bridge consists of three spans of about 315 feet each.

§ 82. *St Louis and Illinois Bridge.*—The St Louis and St Louis Bridge.

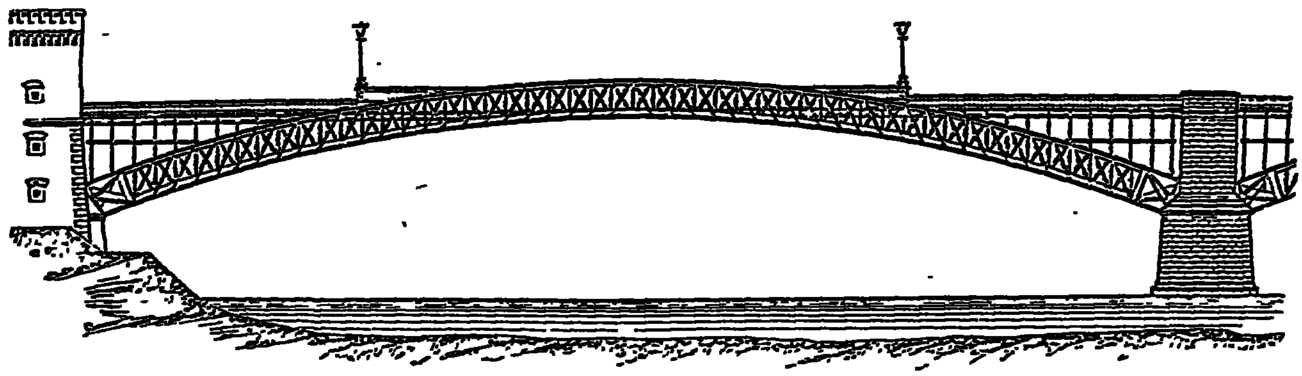

FIG. 133.—Arch of Bridge at Coblentz.

Illinois bridge over the Mississippi (fig. 5, Plate XVIII.) is the finest example of a metal arch yet erected. It is described as follows by Sir Charles A. Hartley who visited it in 1873:—

"The Mississippi at St Louis is confined to a single channel 1600 feet wide and 8 feet deep at extreme low water by an embankment or levee on the Illinois side, which is carried up to the level of extreme high water, at which time the width is augmented to 2200 feet. Both shores are revetted below the low water, some with rubble stones, and protected by the wharf pavements above that line. The extreme range between high and low water is 41 feet. Owing to the narrow gorge through which the whole volume of the Mississippi flows the variations in the bed of the river are very great. Captain James B. Eads, M. Inst. C.E., the distinguished engineer who designed the bridge and superintended its construction, informed the author that a rise of 13 feet less than high-water mark caused a scour of 18 feet, and that in the freshet of 1870 the scour reached a depth of 51 feet below low-water mark alongside the east pier. These facts induced him to believe it possible that the scour, at times of extraordinary high flood, might extend even to the rock itself. He therefore determined to establish the piers and abutments on the rock; and this was done by means of caissons provided with air chambers and locks at depths for the east pier and east abutment reaching 136 feet below high-water mark, or 110 feet from the surface of the water where the foundation work was actually performed. This feat, which was satisfactorily executed in 1870–71, is quite unprecedented in the annals of engineering.

The piers and abutments are composed of coursed rubble masonry up to low-water mark. Above this level they are faced

with grey granite from the State of Maine, which cost £10 per cubic yard *in situ*. The interior of the work is of magnesian limestone. The massive appearance of the granite rock facing is very striking.

The contract prices, and the total quantities of the steel and iron work required for the bridge, are as follows :—

2,500	tons of steel, at £60 per ton	} of 2000 lbs.	
500	,, wrought iron, at £40 per ton...		
1,000	,, rolled iron, at £28 per ton......		
200	,, cast-iron at £16 per ton............	of 2240 lbs.	

The bridge has three spans, each formed with ribbed arches made of cast steel, a novelty in bridge building. The centre span is 520 feet and the side ones 502 feet in the clear.

The rise of the centre arch is 47½ feet, that of the side ones 46 feet each. These are by far the largest arched spans in the world, and under the able direction of Colonel Read, Captain Eads's chief assistant, they are now being rapidly erected gradually from each pier and abutment without the aid of centering. Each span is composed of four double ribs of steel (well braced together at their relative distances from each other), and the tubes forming them are jointed butt to butt. They are clasped together by wrought iron couplings (which proved to be much better than steel), furnished with parallel grooves corresponding with similar grooves in the tubes. Steel pins, varying from 4½ inches to 7 inches in diameter, pass through the centre of the couplings and the ends of the tubes at every joint. The vertical bracing between the upper and the lower tubular ribs, which are 12 feet apart from centre to centre, convert the two members into a single arch.

At the time of the author's visit two of the openings were already spanned by the steel tubes, which are all 18 inches in diameter, and 12 feet to 13 feet long, but of thicknesses varying from 1¼ inches to 2¼ inches.

The arches are to carry a double railroad track, and above the track a roadway 54 feet wide for carriages and foot passengers."

The bridge was opened, subsequently to Sir C. Hartley's visit, on the 4th July 1874.

§ 83. *Projected Bridges.*—The Tay Bridge is a railway bridge in course of construction (1876), to form a connection between the town of Dundee and the North British Railway system in Fife, and crosses the Firth of Tay about a mile and a half to the west of Dundee. The length of the bridge exceeds two miles. It will therefore be the longest iron bridge in the world. The following description has been furnished by Mr A. D. Stewart, who assisted the chief engineer, Mr T. Bouch, in the design of the bridge :—

Curves.—Commencing at the south shore, the bridge for the first five spans is on a curve of a quarter of a mile radius. It is then straight for a distance of a mile and a half. At the north shore, between high and low water mark, it describes a curve of a quarter of a mile radius, forming nearly a quarter of a circle towards the town of Dundee.

Gradients.—The level of the rails at the south end of the bridge is 78 feet above high water. The gradient descends 1 in 100 for the first three spans; it is level for the next two spans; it then ascends 1 to 353 towards the centre of the bridge. Over the navigable part of the river it is level, and the rails are 92 feet above high water, leaving 88 feet for the passage of shipping above high water of spring tides. From this the gradient falls 1 in 73½ to the end of the bridge.

Spans.—The portion of the bridge at present being executed extends to 3120 yards. It is intended to add an opening of 120 feet and a number of 27 feet spans at the north end. The magnitude of the several spans in order, commencing at the Fife shore, is as follows:—3 spans of 60 feet, 2 of 80 feet, 10 of 120 feet, 12 of 136 feet, 13 of 230 feet, 1 of 150 feet, 11 of 120 feet, 25 of 60 feet, 1 of 155 feet, and 6 of 27 feet—the total number of spans being thus 84.

whole material above the rock was thus excavated, the working chamber and shaft of the caisson were filled with concrete, put in in a liquid state, and when this solidified the building upwards of the pier was continued. A difficulty arose in keeping the cylinders vertical during the sinking. This was overcome by combining them into a single caisson. Between the fourteenth and fifteenth pier the rock disappears. At the sites of the next six piers the bed consists of a layer of hard material resting on silt. It is proposed to pile these piers from an outside staging within an oval-shaped wrought iron caisson. After the piles are driven, their heads are to be surrounded with concrete, the water is then to be pumped out of the caisson, and brickwork to be built up to the level of about 5 feet above high water. The upper portions of these, and of all the piers to the north of them, are to consist of cast-iron columns braced together.

From the twenty-second pier northwards the bed of the river consists of sand, with occasional layers of coarse gravel and boulders. It was, however, necessary to modify the designs for the piers, and the method of founding and building them, according to the load each had to carry.

For the 120 and 136 feet spans there are eighteen piers. For each pier two wrought iron caissons are prepared, partly cylindrical and partly conical in shape, and having a base of 15 feet. These are built on the fore-shore, and lined with brickwork; they are then floated out by means of pontoons having hydraulic machinery for lowering: when they have been sunk in their proper place until they take a bearing in the sand, the pontoons are removed, and by means of sand-pumps the material from the interior is removed and they sink by their own weight. During the operation of sinking, rings of wrought iron and brickwork are added to the top of the caisson, and stones are laid round the outside to fill the void caused by the scour and pumping. When a sufficient depth has been obtained the pumps are removed, and the interior is filled with liquid concrete; and when this has solidified, the brickwork is continued to above high water.

For the 230 feet spans, large wrought iron caissons of a cylindrical form, 31 feet in diameter, are erected on the fore-shore, one for each pier, and lined with brickwork to the height which it is intended to sink them in the sand. The upper and temporary portion of the caisson, of the same diameter as the under, but with no lining of brickwork, is placed on the top of the lower part and bolted securely to it. The compound caisson is floated out and sunk, as above described, by means of sand-pumps, and the permanent portion of the caisson is filled with concrete. The temporary portion is then unbolted by divers, and removed for further use. From the surface of the ground to above low water, the pier consists of a brick oval-shaped hollow cylinder, which is built on the fore-shore on girders; and when it has thoroughly set, it is also floated out and lowered on the concrete foundation. The interior of this brick pier is then filled with concrete, and the building of the brickwork is continued to above high water as tidal work.

For the 60 feet spans towards the north end of the bridge, the piers consist of three braced cast-iron columns placed in a row across the bridge, the western column having a rake or batter of 1 in 3. Every fourth pier is double. Some of these were sunk as screw piles, others were founded in 6 feet cylinders, previously sunk by sand-pumps, and filled with concrete.

Superstructure.—The superstructure consists wholly of wrought iron girders. With the exception of two spans which have girders of the bowstring form, they have the top and bottom members straight and parallel. The bracing is of the double lattice form, crossing nearly at right angles, and from the point of intersection a vertical support is carried to the member on which the cross-girder or beam rests. The girders for the 230 feet spans, and the bowstring girders, have wrought iron cross girders resting on, and rivetted to, the lower member on which the roadway is placed. All the others have timber cross-beams resting on and rivetted to the top flange, and the roadway is above these girders. They are sent to the Tay built in convenient pieces for shipment, and rivetted together on jetties prepared near the shore. They are then floated out and raised to their places by machinery suited to their respective weights. They are generally continuous in groups of four consecutive spans. In order to make continuity perfect, the further end of each girder is raised through a certain calculated height before rivetting it to the next.

Montreal papers state that a bridge 15,500 feet in length is about to be constructed over the St Lawrence at Montreal, from the designs of Mr Legge. It will have one span of between 500 and 600 feet, and 60 smaller spans, with a height of 130 feet above the water at high tide. The estimated cost is £800,000.

§ 84. *Statistics.*—Table XVI., from the 8th edition, gives some statistical information as to the weight, cost, and dimensions of some of the principal cast-iron bridges.

Tables XVII. and XVIII. give various details regarding some important bridges of various construction and dimensions.

* Platform.

INDEX OF PRINCIPAL SUBJECTS.

INDEX OF REFERENCES TO BRIDGES.

LIST OF TABLES.

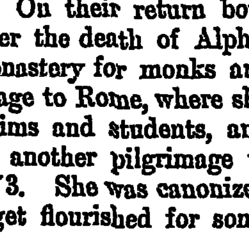
(F. J.)

BRIDGET, St, one of the patron saints of Ireland, who lived during the 6th century, was a daughter of one of the princes of Ulster, and took the monastic vow at a very early age. Her cell, the first in Ireland, was erected under a large oak tree, whence the place was called Kil-dara, the cell of the oak. The city of Kildare is supposed to derive its name from St Bridget's cell. A whole collection of miraculous stories have clustered round her name, and her reputation was not confined to Ireland, for St Bride was a favourite saint in England and in Scotland.

BRIDGET, St, of Sweden, was born about the year 1302. She was descended from a family of royal blood, and at the age of sixteen was married to Alpho, prince of Nericia. The husband and wife were equally devoted to works of piety, and undertook together a pilgrimage to the shrine of St Jago de Compostella. On their return both embraced the monastic life, and after the death of Alpho, his wife founded a new kind of monastery for monks and nuns. She then went on a pilgrimage to Rome, where she founded a house for Swedish pilgrims and students, and composed her *Revelationes*. After another pilgrimage to Jerusalem, she died at Rome in 1373. She was canonized in 1391. The order of St Bridget flourished for some time; they had one house in Britain.

BRIDGETOWN. See Barbados, vol. iii. p. 359.

BRIDGEWATER, or Bridgwater, a municipal (once a parliamentary) borough and seaport in Somerset, on the Great Western Railway, 29 miles S.S.W. of Bristol. It is pleasantly situated in a level and well-wooded country, having on the east the Mendip range and on the west the Quantock hills. The town, which is well built, lies along both sides of the River Parret, here crossed by a handsome iron bridge. It has an ancient Gothic church with a spire 174 feet in height, a town-hall, court-rooms, a jail, a market-place, an infirmary, a free grammar school, and some alms-houses. The river, which is subject to a bore, often two fathoms deep at the mouth, is navigable for vessels of 700 tons up to the town. The customs duties in 1874 were £7227. The chief imports are grain, coals, wine, hemp, tallow, and timber; the exports, agricultural produce, earthenware, cement, plaster of Paris, and bath-bricks, which last constitute the staple trade of the town. The value of the imports in 1874 was £118,509, and of the exports £5011. The town returned two members to parliament till 1870, when the borough was disfranchised. Population in 1871, 10,259. Bridgewater is said to derive its name, which appears in earlier times as Brugge Walter, from a certain Walter de Douay, to whom the manor was presented at the Conquest. In the reign of Henry II. a splendid castle was built and a harbour constructed by William de Briwere; and in 1230 a Grey-Friars' monastery was founded by his son. The castle was taken by the Royalists in 1643, and was almost completely demolished after its capture by the Parliamentary forces in 1645. Admiral Blake was a native of Bridgewater.



Arms of Bridgewater.

difficulties that retarded the accomplishment of his project, together with the pecuniary restrictions he imposed on himself in order to supply the necessary capital, affords an instructive example of that energy and self-denial on which the success of great undertakings so much depends. Though a steady supporter of Mr Pitt's administration, he never took any prominent part in politics. On his death, March 8, 1803, the ducal title became extinct.

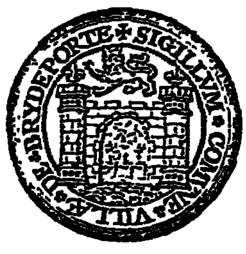
BRIDGEWATER, the Rev. Francis Henry, eighth earl of, was born in 1758 and died on the 11th February 1829. He is best known as the originator of the *Bridgewater Treatises*. By his will he devised the sum of £8000, at the disposal of the president of the Royal Society, to be paid to the author or authors selected by the president to write and publish 1000 copies of a treatise "On the Power, Wisdom, and Goodness of God, as manifested in the Creation." Mr Davies Gilbert, who then filled the office, selected eight persons, each to undertake a branch of this subject, and each to receive £1000 as his reward, together with any benefit that might accrue from the sale of his work, according to the will of the testator.

The treatises were published as follows:—1. *The Adaptation of External Nature to the Moral and Intellectual Condition of Man*, by the Rev. Thomas Chalmers, D.D. 2. *The Adaptation of External Nature to the Physical Condition of Man*, by John Kidd, M.D. 3. *Astronomy and General Physics considered with reference to Natural Theology*, by the Rev. William Whewell, D.D. 4. *The Hand, its Mechanism and Vital Endowments as evincing Design*, by Sir Charles Bell. 5. *Animal and Vegetable Physiology considered with reference to Natural Theology*, by Peter Mark Roget. 6. *Geology and Mineralogy considered with reference to Natural Theology*, by the Rev. William Buckland, D.D. 7. *The Habits and Instincts of Animals with reference to Natural Theology*, by the Rev. William Kirby. 8. *Chemistry, Meteorology, and the Function of Digestion, considered with reference to Natural Theology*, by William Prout, M.D. The works are of unequal merit; several of them took a high rank in apologetic literature.

BRIDLINGTON, Brellington, or Burlington, a market-town of England, in the East Riding of Yorkshire, on the North-Eastern Railway, 23 miles from Scarborough. It lies about a mile from the coast on a gentle acclivity. The streets are narrow and the houses irregularly built. A large chamber over the old priory gateway (of the time of Richard II.) is used as a town-hall. The town has also a corn exchange, a temperance hall, a mechanics' institute, and two subscription libraries. The parish church of St Mary's preserves a considerable part of the Augustinian priory which was erected in the 12th century, by Walter de Gaunt, a relative of the Conqueror, and continued to flourish till 1537, when its last prior was executed for taking part in the "Pilgrimage of Grace." On the coast is situated the pleasant watering-place of Bridlington Quay, which has recently increased in reputation. The harbour is enclosed by two stone piers, and there is good anchorage in the bay. The beach consists of a fine firm sand, and is bordered by a parade with ornamental gardens. Besides hot and cold baths, there is a chalybeate spring esteemed for its medicinal properties; and the town is supplied with drinking-water from an intermittent fountain discovered below high water mark in 1811. The most important public building is the Victoria Rooms, which comprise a ball-room, a reading-room, a news-room, &c. The united population of *Bridlington and Bridlington Quay*, which in 1851 was 2432, amounted in 1871 to 6203. Bridlington was placed by Henry I. under the civil jurisdiction of the priors, and by John was allowed to hold a market and an annual fair. In 1643 the town was cannonaded by Admiral Batten, on account of the presence of Queen Henrietta, who had landed with a supply of arms. Sir George Ripley and John de Bridlington were connected with the priory; Kent the landscape-gardener was a native of the town; and his patron, Robert Boyle, bore the title

of earl of Burlington, from which the name of Burlington House in London is derived.

BRIDPORT, a parliamentary and municipal borough and market-town of England, in the county of Dorset, 18 miles by rail N.W. from Dorchester between two branches of the River Brit, from which it takes its name. The main part of the town is about a mile from the sea, with which it is connected by a single winding street, terminating in a quay surrounded by a fishing village. The principal buildings comprise a town-hall, a market-house, a jail, a custom-house, a mechanics' institute with reading and lecture rooms; there are also a school of art, alms-houses, and several charities. The parish church of St Mary, a cruciform edifice in the Perpendicular style, was restored in 1865. The harbour, which had become choked with sand, was rendered available and secure for vessels of 250 tons by extensive improvements undertaken in 1742 and 1823. The total value of the imports, which consist mainly of timber, coal, and flax, was in 1874 £89,616; and the exports amounted to £18,021. Its principal articles of manufacture have long been sail-cloth, cordage, linen, and fishing-nets. Bridport formerly returned two members to parliament, but since 1868 it returns only one. The population was 7670 in 1871. Though a place of considerable antiquity, it has very little historical importance. Its mint is mentioned in *Domesday Book*. In the reign of Henry VIII. the town and district had a monopoly of the supply of cordage for the Royal Navy.



Arms of Bridport.

BRIEG, the capital of a circle in the Prussian province of Silesia and government of Breslau, is situated on the left bank of the Oder, and on the Breslau and Oppeln Railway, 27 miles S.E. of the former town. It is well built, and has a castle (the residence of the old Piastic counts of Brieg), a lunatic asylum, a gymnasium with a good library, and several churches and hospitals. Its fortifications were destroyed by the French in 1807, and are now replaced by beautiful promenades. Brieg carries on a considerable trade, its chief manufactures being linen, cotton, and woollen goods, porcelain and machinery, hats, pasteboard, and cigars. Important cattle-markets are held there. Brieg, or, as it is called in early documents, *Civitas Altæ Ripæ*, obtained municipal rights in 1250 from Duke Henry III. of Breslau, and was fortified in 1297; its name is derived from the Polish *Brzeg* (shore). In the 14th century it became the seat of a line of counts, by one of whom the castle was built in 1341. Burned by the Hussites in 1428, the town was soon afterwards rebuilt, and in 1595 it was again fortified by Duke Joachim Frederick. In the Thirty Years' War it suffered greatly; in that of the Austrian succession it was heavily bombarded by the Prussian forces; and in 1806 it was captured by the French. Population in 1871, 15,372.

BRIEL, BRIELLE, or BRIL, a fortified seaport town of Holland, in the province of South Holland, and capital of an arrondissement, stands on the north side of the island of Voorne, near the mouth of the Maese, 14 miles west of Rotterdam, in 51° 54′ 11″ N. lat. and 4° 9′ 51″ E. long. The town is well built and strongly fortified, and has an arsenal, military magazines, barracks, and a good harbour. The tower of St Catharine's church serves as a lighthouse. Briel is remarkable in history as having been the first place captured in the struggle that resulted in the independence of the Netherlands—a fact which is commemorated in the popular rhyme, *Den eerste van April verloor duc d'Albe syne Bril*, punning on the meaning of Bril, which is the Dutch for "spectacles." Admiral Van Tromp was born in the town. The inhabitants, who are principally engaged as fishermen and pilots, numbered 4058 in 1869.

BRIGADE, a tactical body, composed of two or more regiments of cavalry or infantry, under the command of a general officer of the lowest grade. The term *brigade* is also applied to from four to eight batteries of artillery working together, and to the small detachments (eight or nine men) of engineers employed in excavating saps in siege operations. Two or more brigades constitute a division, two or more divisions a corps d'armée, two or more corps d'armée an army.

BRIGADE-MAJOR, a third-class staff officer, appointed by the brigadier to assist him in the management of his brigade.

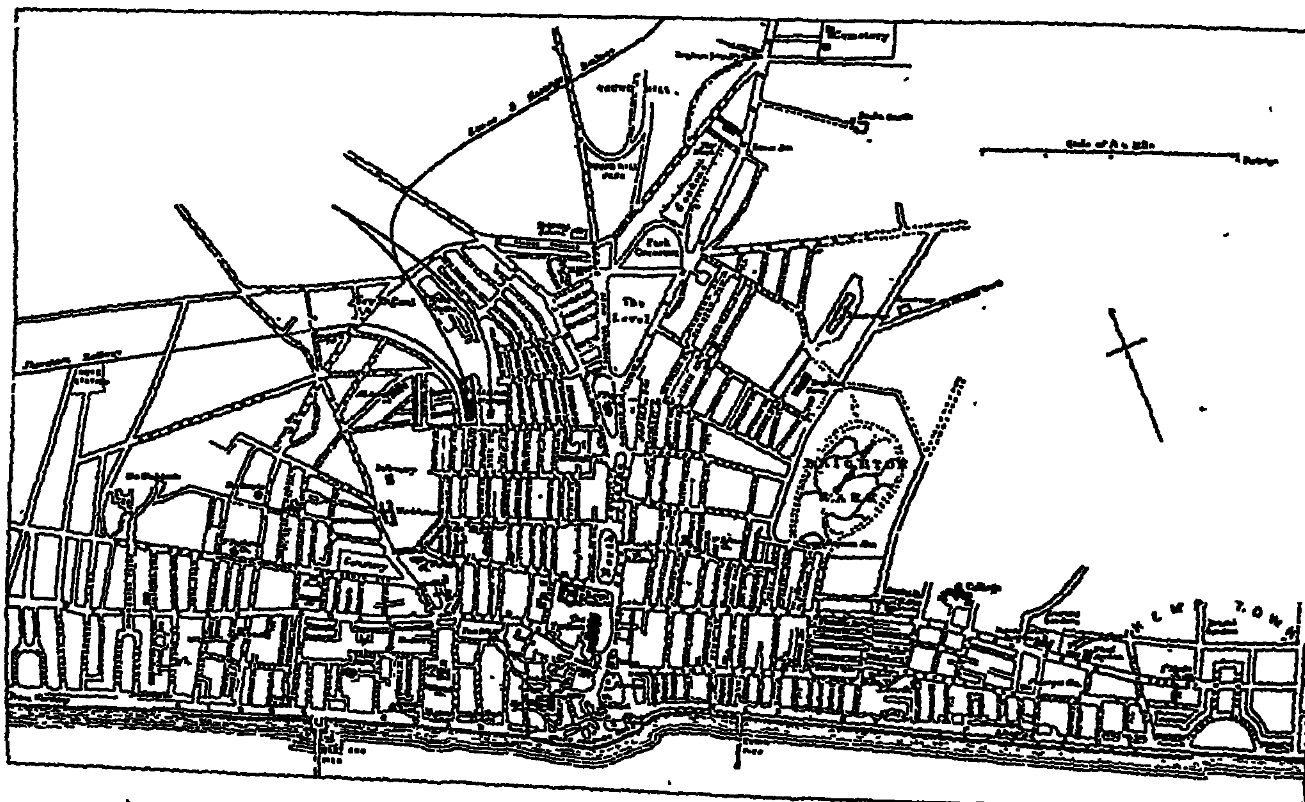
BRIGADIER, a general officer of the lowest grade, next in rank above a colonel, who is intrusted with the command of a brigade.

BRIGGS, HENRY, one of the greatest mathematicians of the 16th century, was born in 1556 at Warley Wood near Halifax, in Yorkshire. He studied at St John's College, Cambridge, graduated in 1581, and obtained a fellowship in 1588. In 1592 he was made reader of the physical lecture founded by Dr Linacre, and in 1596 first professor of geometry in Gresham House (afterwards College), London. In his lectures at Gresham House he proposed the alteration of the scale of logarithms from the hyperbolic form which Napier had given them, to that in which unity is assumed as the logarithm of the ratio of ten to one; and soon afterwards he wrote to the inventor on the subject. In 1616 he paid a visit to Napier at Edinburgh in order to discuss the suggested change; and next year he repeated his visit for a similar purpose. During these conferences the alteration proposed by Briggs was agreed upon; and on his return from his second visit to Edinburgh in 1617 he accordingly published the first chiliad of his logarithms. In 1619 he was appointed Savilian professor of geometry at Oxford, and resigned his professorship of Gresham College on the 25th of July 1620. Soon after his settlement at Oxford he was incorporated master of arts in that university, where he continued a laborious and studious life, employed partly in discharging the duties of his office, and partly in the computation of logarithms and in other useful works. In 1622 he published a small tract on the *North-West Passage to the South Seas, through the Continent of Virginia and Hudson's Bay*; and in 1624 he printed at London his *Arithmetica Logarithmica*, in folio, a work containing the logarithms of thirty thousand natural numbers to fourteen places of figures besides the index. He also completed a table of logarithmic sines and tangents for the hundredth part of every degree to fourteen places of figures besides the index, with a table of natural sines to fifteen places, and the tangents and secants for the same to ten places; all of which were printed at Gouda in 1631 and published in 1633 under the title of *Trigonometria Britannica*. Briggs died on the 26th of January 1630 in the 74th year of his age. Dr Smith, in his *Lives of the Gresham Professors*, characterizes him as a man of great probity, a contemner of riches, and contented with his own station, preferring a studious retirement to all the splendid circumstances of life.

His works are—1. *A Table to find the Height of the Pole, the Magnetical Declination being given*, London, 1602, 4to. 2. "Tables for the Improvement of Navigation," printed in the second edition of Edward Wright's treatise entitled *Certain Errors in Navigation detected and corrected*, London, 1610, 4to. 3. *A Description of an Instrumental Table to find the part proportional, devised by Mr Edward Wright*, London, 1616 and 1618, 12mo. 4. *Logarithmorum Chilias prima*, London, 1617, 8vo. 5. *Lucubrationes et Annotationes in opera posthuma J. Neperi*, Edin., 1619, 4to. 6. *Euclidis Ele-*

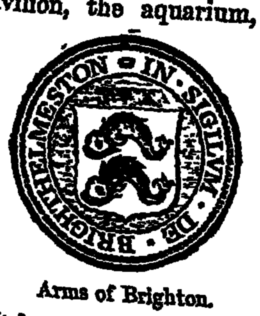
mentorum VI. libri priores, London, 1620, folio. 7. *A Treatise on the North-West Passage to the South Sea*, London, 1622, 4to, reprinted in Purchas's *Pilgrims*, vol. iii. p. 852. 8. *Arithmetica Logarithmica*, London, 1624, folio. 9. *Trigonometria Britannica*, Goudæ, 1663, folio. 10. Two *Letters* to Archbishop Usher. 11. *Mathematica ab Antiquis minus cognita*. Some other works, as his *Commentaries on the Geometry of Peter Ramus*, and *Remarks on the Treatise of Longomontanus respecting the Quadrature of the Circle*, have not been published.

BRIGHTON, a parliamentary borough, and one of the most fashionable watering-places of England, is situated on the coast of Sussex between Beachy Head and Selsea Bill, in 50° 50′ N. lat. and 0° 8′ W. long. By railway it is 50 miles from London and 28 from Chichester. Its sea-frontage of handsome mansions and hotels extends upwards of three miles from Kemp Town in the east to what was formerly the suburban village of Cliftonville in the parish of Hove; while its depth inland at the centre is rather more than a mile. In general appearance the style of the town strikingly resembles that of London; and many of its streets and squares seem as if they had been transported as they stand from the "West End." As far, indeed, as its character is not affected by its natural situation, it is nothing more or less than a vigorous offshoot supported by the sap of the greater city, a fact which is popularly recognized by the designation of London-super-Mare. During the present century its growth has been rapid and continuous, about four hundred new houses being often built in the space of a year. Its streets and squares already amount to four hundred; but in comparison with this extent the number of its really remarkable buildings is rather small, and nearly all of them are of modern date. Among its twenty Episcopalian and between thirty and forty Nonconformist churches two only need be specially mentioned,—the parish church of St Nicholas, which was built



Plan of Brighton.

in the reign of Henry VII., and is probably one of the oldest buildings in the town, and Trinity chapel, in Ship Street, memorable as the scene of the labours of Frederick William Robertson. The most important of the secular edifices are the town-hall, the market, the pavilion, the aquarium, the theatre, the proprietary college, the Sussex county hospital, the new workhouse, the infirmary, the blind asylum, and the female orphan asylum. The pavilion, with its strange assemblage of domes and minarets, was built in 1784–7 as a residence for the Prince of Wales (afterwards George IV.), and about 1818 it was refashioned by Nash into a grotesque imitation of Chinese architecture. It has a frontage to the east of 300 feet, and occupies, with its gardens, about 11½ acres. In 1850 it was purchased by the town for £53,000, and its spacious rooms, greatly altered from time to time, are now appropriated to a variety of uses,—one serving as a museum, another as an assembly-room, others as picture-galleries. The pavilion dome, formerly the royal stables, is now converted into a magnificent hall for high-class musical performances; it is lighted by a glazed dome, with



Arms of Brighton.

a diameter only 20 feet less than that of the dome of St Paul's of London. The county hospital was built in 1828 by Sir Charles Barry, at a cost of £10,000, and has since been largely extended. It is "open to the sick and lame poor of every country and nation." There are a large number of minor benevolent establishments in the town, and so various are its educational institutions that it has been called the city of schools. Among the bathing establishments the most remarkable are Brill's and the New Turkish Baths; the former includes extensive swimming baths for both sexes.

The tendency of the currents in the channel opposite Brighton is to drive the shingle eastward, and within the memory of man large portions of the coast have thus been destroyed. To prevent this erosion the whole sea-frontage of the town at the east end is protected by a great sea-wall, which was built between 1827 and 1838. It is a mile long, 60 feet high, and 23 feet thick at the base, and cost £100,000. The beach is further ribbed from north to south by various "groynes," or jetties, one of which, constructed of concrete in 1867, at a cost of £5000, stretches about 250 feet into the sea. There are two piers which serve as promenades. The first, an elegant chain fabric commenced by Sir S. Brown, R.N., in 1822, was

opened to the public in the following year. It is 1136 feet in length and 15 feet in width, the four cast-iron columns on which it is suspended being supported by stone buttresses based on oaken piles driven into the solid chalk. The cost was £30,000, and in 1836 an additional expenditure was necessary to repair the damage inflicted by a great storm in November of that year, which was within a little of destroying the structure altogether. A new pier further to the west was opened in 1866. Its total length is 1115 feet, and it affords accommodation for 2000 people. The town is well supplied with water by the corporation waterworks, and by an artesian well, 1285 feet deep, at Warren Farm, the boring of which lasted from 1858 to 1862. The sewage is effectively removed by an intercepting sewer 5 miles in length, which discharges into the sea 2 miles east of the parish boundary. Since the opening of the Brighton railway in 1841 the town has developed wonderfully; but, with the exception of the railway works, no manufacturing establishment exists, and no tall chimneys are seen. Owing to the absence of a natural harbour the commerce of the place is insignificant, but the mackerel and herring-fisheries are carried on by about 120 boats. The races, which are held in August to the north and north-east of the town, and the great volunteer reviews, which of late years have drawn many thousands to the neighbouring downs, add considerably to the local trade. The town is governed by a mayor, thirteen aldermen, and a council. It returns two members to parliament.

Brighton, originally Brighthelmstone, plainly derives its name from some Saxon Brighthelm, but who or what he was there seems no means of discovering. The present contracted form of the word came into general use only in the end of the 18th century, but it is sometimes found in the documents of the time of Charles II. At the time of the Conquest Brighton was a small fishing village, and the lordship of the manor was bestowed by the Conqueror on his nephew William de Warrenne, who received as rent from the fishermen 4000 herrings. In 1513 it was burnt by the French under Messire Pregent, whom the English chronicles call Prior John; and in 1545 it was again greatly damaged by Claude d'Annebalte, the admiral of Francis I. At that time it is represented as a quadrangular town of four or five streets. There were then no defences, but in 1558 a small circular fort was erected by Elizabeth. The town seems to have rapidly recovered its prosperity, for in 1579 it possessed 80 fishing-boats, with 400 fishermen and 10,000 nets. The whole Elizabethan town, however, has been destroyed by the sea, which in 1699 swept away 160 houses, and in 1703 and 1706 did almost as much damage. The modern reputation of Brighton is due to Dr Richard Russell, a native of Lewes, who resided there in 1750, and wrote a book on the advantages of sea-bathing, which led a number of people of high rank—among others the dukes of Cumberland and Marlborough—to place themselves under his direction. The Prince Regent followed, and the fortunes of Brighton were made. Bedford Square was commenced in 1810, and the building of Kemp Town took place between 1821 and 1830. A charter of incorporation was granted in 1854. In 1761 the population was only about 2000; in 1801 it had risen to 7339, by 1841 to 46,567, and by 1851 to 69,673. In 1861 there were 77,693 inhabitants in the municipal borough, and 87,317 within the parliamentary limits, the number of houses being respectively 12,727 and 13,983, while in 1871 the municipal borough had a population of 90,011, inhabiting 14,438 houses, and the parliamentary borough 103,758, with 16,284. See Lower's *History of Sussex*, 1870, and papers in the *Sussex Archæological Collections*.

BRIGHT'S DISEASE, a term in medicine applied to a class of diseases of the kidneys which have as their most prominent symptom the presence of albumen in the urine, and frequently also the co-existence of dropsy. These associated symptoms in connection with kidney disease were first described in 1827 by Dr Richard Bright. Since that period the subject has been investigated by many able physicians, and it is now well established that the symptoms above named, instead of being as was formerly supposed the result of one form of disease of the kidneys, may be dependent on various morbid conditions of those organs. Hence the term Bright's disease, which is retained in medical nomenclature in honour of Dr Bright, must be understood as having a generic application.

Two varieties of Bright's disease are described, the *acute* and the *chronic*,—the former representing the inflammatory and the latter the degenerative form of kidney disease.

Acute Bright's Disease (synonyms—*acute desquamative nephritis, acute albuminuria*, &c.) commonly arises from exposure to cold, from intemperance, or as a complication of certain acute diseases, such as erysipelas, diphtheria, and especially scarlet fever, of which it is one of the most frequent and serious consequences. In this form of the disease the kidneys become congested, their blood-vessels being gorged with blood, while the tubules are distended and obstructed by accumulated epithelium, as also by effused blood and the products of inflammation, all which are shed off and appear in the urine on microscopic examination as *casts* of the uriniferous tubes.

The symptoms to which the condition gives rise are usually of a severe character. Pain in the back, vomiting, and febrile disturbance commonly usher in the attack. Dropsy, varying in degree from slight puffiness of the face to an accumulation of fluid sufficient to distend the whole body, and to occasion serious embarrassment to respiration, is a very common accompaniment. The urine is reduced in quantity, is of dark, smoky, or bloody colour, and exhibits to chemical reaction the presence of a large amount of albumen, while, under the microscope, blood corpuscles and casts, as above mentioned, are found in abundance.

This state of acute inflammation may by its severity destroy life, or, short of this, may by continuance result in the establishment of one of the chronic forms of Bright's disease. On the other hand an arrest of the inflammatory action frequently occurs, and this is marked by the increased amount of the urine, and the gradual disappearance of its albumen and other abnormal constituents; as also by the subsidence of the dropsy and the rapid recovery of strength.

Of *chronic Bright's Disease* there are several forms, named according to the structural changes undergone by the kidneys. The most frequent of these is the *large white kidney*, which is the chronic form of the desquamative nephritis above mentioned.

Another form of chronic Bright's disease is the *waxy* or *amyloid kidney*, due to the degenerative change which affects first the blood-vessels and subsequently also the tubular structures of the organ. This condition is usually found associated with some chronic ailment of an exhausting character, such as disease of bones and other scrofulous affections, or with a generally enfeebled state of health. It is marked by the passage of large quantities of albuminous urine, and is frequently accompanied with general dropsy, as also with diarrhœa and consequent loss of strength. A third form of chronic Bright's disease is the *contracted kidney*, depending on the condition known as *cirrhosis*, in which the kidneys become reduced in bulk, but dense in texture, from an abnormal development of their connective tissue and relative atrophy of their true structure. This form of the disease, which is commonly, though not exclusively connected with a gouty constitution, is apt to escape detection in its earlier stages from the more obscure character of the symptoms, there being less albuminuria and less dropsy than in the other varieties. Its later progress, however, enables it to be readily recognized. Dimness of vision, due to a morbid condition of the retina, and also hypertrophy of the heart leading to fatal apoplexy, are frequent accompaniments of this form of the disease.

A fourth variety of chronic Bright's disease is described by authors on the subject, viz., *fatty degeneration of the kidneys*, occasionally occurring in old age and in connection with a similar degeneration of other organs.

The kidneys being among the most important excretory organs of the body, it follows that when their function is interrupted, as it is alike in acute and chronic Bright's disease, serious results are apt to arise from the retention in the economy of those effete matters which it is the office of the kidneys to eliminate. The blood being thus contaminated, and at the same time impoverished by the draining away of its albumen from the kidneys, is rendered unfit to carry on the processes of healthy nutrition; and, as a consequence, various secondary diseases are liable to be induced. Inflammatory affections within the chest are of frequent occurrence, but the most dangerous of all the complications of Bright's disease are the nervous symptoms which may arise at any stage, and which are ascribed to the effects of uræmic poisoning.

In the treatment of acute Bright's disease, good results are often obtained from local depletion, from warm baths, and from the careful employment of diuretics and purgatives. Chronic Bright's disease is much less amenable to treatment, but by efforts to maintain the strength and improve the quality of the blood by strong nourishment, and at the same time by guarding against the risks of complications, life may often be prolonged in comparative comfort, and even a certain measure of improvement be experienced.

See *Report on Medical Cases*, by Richard Bright, London, 1827; *On Granular Degeneration of the Kidneys*, by Robert Christison, M.D., Edinburgh, 1839; *Diseases of the Kidney*, by Dr G. Johnson, London, 1866; *Practical Treatise on Urinary and Renal Diseases*, by Wm. Roberts, M.D., London, 1865; *On the Pathology and Treatment of Albuminuria*, by W. H. Dickinson, M.D., London, 1868; *Practical Treatise on Bright's Diseases of the Kidneys*, by T. Grainger Stewart, M.D., Edin. 1871. (J. O. A.)

BRIGNOLES, the capital of an arrondissement in the department of Var, in France, is situated in a fertile and pleasant valley on the right bank of the Calami, 22 miles N.N.E. of Toulon. It is neat and well built, and has a magnificent fountain, a public library, a normal school, manufactures of silk thread and leather, and an active trade in wines, brandy, liqueurs, and excellent prunes—the last distinctively known as *prunes de Brignoles*. The prefecture has its offices in the palace of the counts of Provence, and the old house of the Templars is occupied by the theological seminary. Brignoles is a town of great antiquity. In 1291 it gave its name to a treaty between Alphonso III. of Aragon and the king of France. In ancient documents it is often mentioned as *Villa Puerorum*, from the fact that the children of the counts of Provence were generally born and brought up in the castle. In 1524 the town was taken and pillaged by Charles V., and in 1588 it met a similar fate at the hands of the Leaguers. Population of town in 1872, 4843.

BRIL, Paul, a Flemish painter, born at Antwerp in 1554. The success of his elder brother Matthew in the Vatican induced him to repair to Rome. On the death of Matthew, Paul, who far surpassed him as an artist, succeeded to his pensions and employments. He painted landscapes with a depth of chiaroscuro then little practised in Italy, and introduced into them figures well drawn and finely-coloured. Many of his pictures are extant in Italy. One of his best compositions is the martyrdom of St Clement, in the Sala Clementina of the Vatican. He died at Rome in 1626. (See Lanzi, *History of Painting*.)

BRINDISI, a fortified city and seaport of Italy, in the province of Otranto, is situated at the head of a bay of the Adriatic in 40° 39′ 27″ N. lat. and 17° 28′ 44″ E. long. The streets are for the most part narrow and crooked, and the town in general is in a somewhat ruinous condition. Since the restoration of its maritime importance, which is mainly due to the fact that it forms the great transit station in the overland route to Asia by the Mont Cenis Railway and the Suez Canal, some improvement has taken place, and it bids fair to become one of the most flourishing cities in the country. The progress, however, has hitherto been comparatively slow, and the only extensive addition which has been effected is a new street leading from the railway station to the harbour. A cathedral in rather a dilapidated state, a citadel with huge round towers (founded by Frederick II. and completed by Charles V.), and a seminary (containing a library bequeathed to the town by archbishop Leo), are the only public buildings worthy of notice. The ruins of the circular church of St Giovanni, which was destroyed by earthquake, are not without interest; an ancient building of uncertain date is popularly regarded as the house where Virgil died; and there is a remarkable column supposed by some to have marked the termination of the Appian Way, but more probably belonging to an ancient temple. There are ten public schools in the town. The trade was represented in 1873 by imports to the value of £344,000, and exports to £325,000. The former consist mainly of raw silk, wheat and flour, coals, manufactured cottons, and petroleum; and the latter of manufactured coral, corn, dried fruits, and olive oil. The number of vessels that arrived at the port in 1873 was 709, of which 422 were steamships. The harbour consists of an outer and an inner portion, and the inner is divided into two basins, extending right and left. The outer port is about 6400 feet long by 3200 wide, the western arm of the inner portion 4800 by 800, and the eastern arm 3520 by 640. An extensive system of dredging has been in operation since 1866, and long lines of quays are being gradually constructed. Graving-docks are also in course of construction; and a lagoon, called *Fiume Piccolo*, close to the outer harbour, which has been a constant source of malaria, is being filled up. The population of the town, which was only 8000 in 1861, had increased to 13,755 in 1871.

Brindisi, *Brundisium*, or Βρεντέσιον, was originally, it would appear, a city of the Sallentines, from whom it was captured by the Romans in 267 B.C. Colonized by its conquerors in 244 B.C., it soon rose into importance, and became their chief naval station in the Adriatic. Hannibal vainly attempted to surprise the city, which remained faithful to Rome through the darkest days of the Punic struggle. During the war between Julius Cæsar and Pompey the former endeavoured to shut up his rival's fleet in the inner harbour, by closing the entrance with wooden piles, which are frequently but erroneously supposed to have been the cause of the destruction of that part of the port. On the fall of the Western Empire Brundisium seems to have been outstripped by the neighbouring city of Hydruntum (Otranto). In the 10th century it was destroyed by the Saracens, but was rebuilt by Spathalupus the Byzantine governor, whose name still stands graven on the marble column above mentioned. After passing through various vicissitudes in common with the rest of Southern Italy, it fell into the hands of the Normans, and in the 11th century it was the scene of the chivalrous pageantry of Tancred's court. It was plundered in 1348 by Louis, king of Hungary, and in 1458 suffered severely from an earthquake. Some time before this last disaster a more serious injury had been inflicted by Prince Giovanni Antonio Orsini, who completely choked the entrance to the inner port by sinking a number of vessels laden with stone. The commercial importance of the city rapidly declined, and it was of no interest save to the classical scholar as the birthplace of Pacuvius, and from its association with the mirthful journey of Horace and the death of Virgil.

BRINDLEY, James, a celebrated engineer, was born at Thornsett, Derbyshire, in 1716. His parents were in very humble circumstances, and he received little or no education. At the age of seventeen he was apprenticed to a millwright near Macclesfield, and while in this employment manifested remarkable mechanical talent. Soon after completing his apprenticeship he set up in business for himself as a wheelwright, and quickly became famous for his ingenuity and skill in repairing all kinds of machinery. In 1752 he designed and set up an engine for draining some coal-pits at Clifton in Lancashire. Three years later he extended his reputation by completing the machinery for a silk-mill at Congleton. About 1754 Brindley became acquainted

with the duke of Bridgewater, and an arrangement was soon come to whereby he undertook to carry out that nobleman's scheme of inland navigation. The duke's primary object was the carriage of coal from his estate at Worsley to Manchester. The difficulties in the way were great, but all were surmounted by the genius of Brindley, whose crowning triumph was the carrying the new canal over the River Irwell at Barton, by means of an aqueduct elevated 39 feet above the water. The great success of this canal, the first of its kind in Great Britain, encouraged similar projects, and Brindley was soon engaged extending his first work to the Mersey. He then designed and nearly completed what he called the Grand Trunk Canal, connecting the Trent and Humber with the Mersey. The Staffordshire and Worcestershire Canal, the Oxford Canal, the Stockwith and Chesterfield Canal, were all planned and carried out by him. His excessive toil broke down his strength, and he died in 1772 at the early age of fifty-six. Brindley was a man of no education; he retained to the last a peculiar roughness of character and demeanour; but his innate power of thought more than compensated for his lack of training. It is told of him that when in any difficulty he used to retire to bed, and there remain intensely pondering his problem until the solution became clear to him. His mechanical ingenuity and fertility of resources were very remarkable; he undoubtedly possessed in the very highest degree the engineering faculty, though the kind of works to which he devoted himself has been cast into the shade by the later developments of steam traffic. Brindley was an enthusiast in his business and possessed with the idea of canals. His reported answer to the committee who asked him what was the use of navigable rivers,—"To feed canals," is characteristic, if not altogether authentic.

See Smiles, *Lives of the Engineers*, vol. i.; *Biographia Britannica.*

BRIOUDE, a town of France, in the department of Haute Loire, capital of an arrondissement, is situated on the left bank of the Allier, 39 miles N.W. of Puy. The town is ill-built, but has a fine old Gothic church (St Julien, of the 12th century, with curious mosaic ornamentation), a college, a public library, and beautiful fountains, which date from the 13th century. At Old Brioude, about three miles S.S.E., are the remains of a bridge over the Allier, which consisted of a single arch 60 feet high and 206 feet in span. (See article BRIDGES, p. 332.) This fell in 1822; and a new bridge of one arch, 182 feet in span, was built in 1845. Population in 1872, 4524.

Brioude, the ancient *Brivas*, was formerly a place of considerable importance. It was in turn besieged and captured by the Goths (532), the Burgundians, the Saracens (732), and the Normans. In 1181 the viscount of Polignac, who had sacked the town two years previously, made public apology in front of the church, and established a body of twenty-five knights to defend the relics of St Julian. For some time after 1361 the town was the headquarters of the lord of Castelnau, who was at the head of one of those bands of military adventurers which then devastated France. The knights (or canons, as they afterwards became) of St Julian bore the title of counts of Brioude, and for a long time opposed themselves to the civic liberties of the inhabitants.

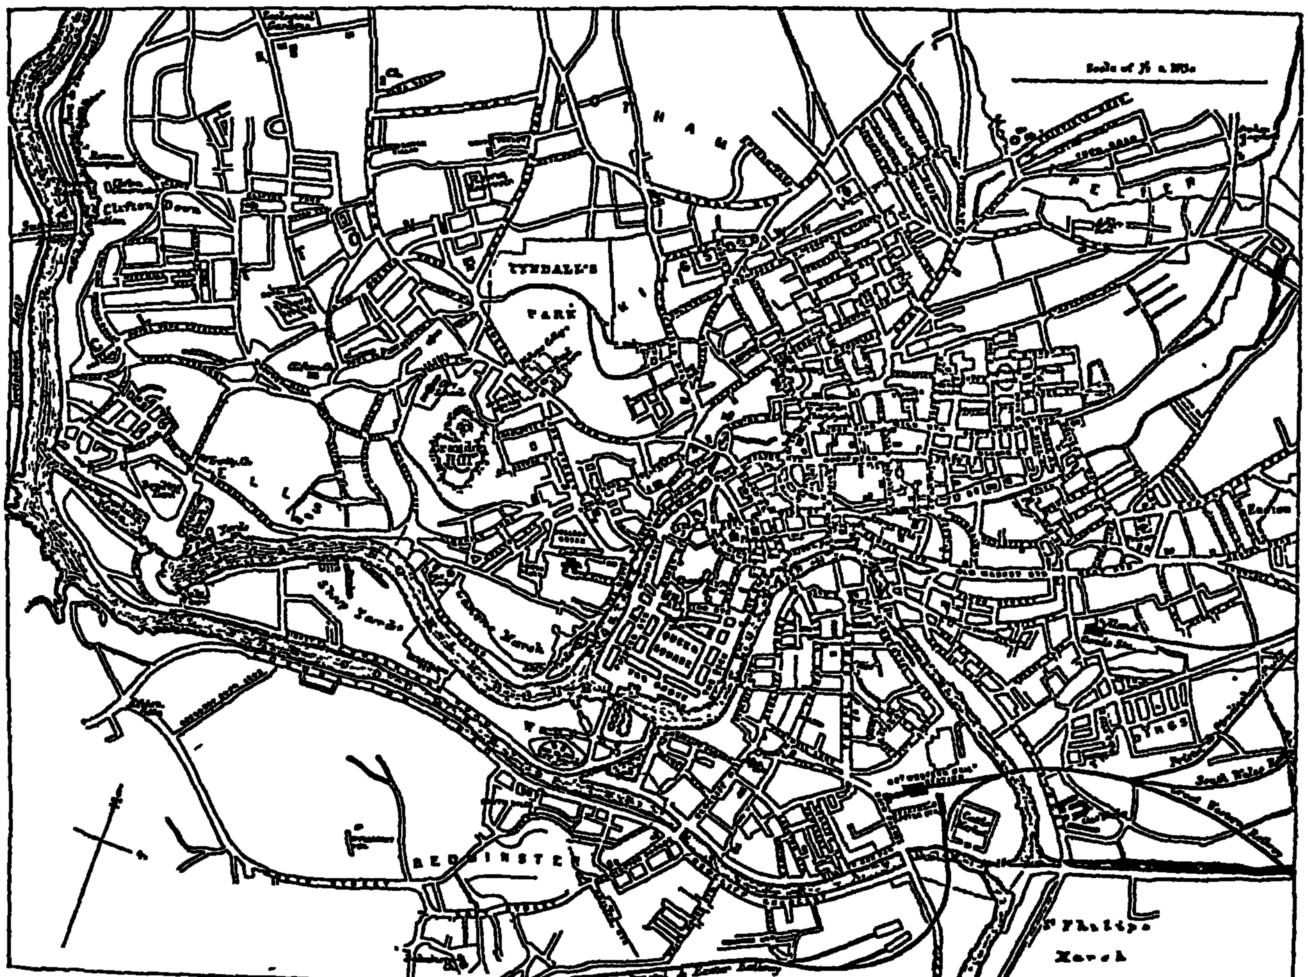
BRISBANE, a town of Australia, capital of the colony of Queensland, is situated in Stanley county, on both banks of the River Brisbane, about 25 miles from its entrance into Moreton Bay. It consists of four parts,—North and South Brisbane, Kangaroo Point, and Fortitude Valley. Among its public buildings are courts of justice, houses of parliament, a governor's residence, a literary institute, a concert-room, a school of arts, and from twenty to thirty churches. It has also an excellent botanical garden. The river, which is about a quarter of a mile broad opposite the town, is navigable for vessels of considerable burden, and has been made more accessible by the partial removal of the bar at its mouth. Regular steam communication is kept up with Sydney and other Australian ports, and a very flourishing trade is carried on in the export of wool, cotton, tallow, and hides, and the import of European manufactures. The town is the centre of a considerable railway and telegraphic system. Brisbane was founded as a penal settlement in 1825, and was named in honour of Sir Thomas M. Brisbane. In 1842 the establishment was abolished, and general colonization set in. The town was politically a part of New South Wales till 1859, when it was made the capital of Queensland. It is the seat of an Anglican and also of a Roman Catholic bishop. Its population was only 5225 by the census of 1861; but in 1871 it amounted to 15,029, of whom 7204 were males and 7825 females. The number of inhabited houses at the latter date was 2931.

BRISBANE, SIR THOMAS MAKDOUGALL, a distinguished soldier and astronomer, was born in 1773 at Brisbane in Ayrshire. He entered the army in 1789, and served in Flanders, the West Indies, and the Peninsula. In 1814 he was sent to North America; on the return of Napoleon from Elba he was recalled, but did not arrive in time to take part at the battle of Waterloo. From 1818 to 1821 he was military commander in the South of Ireland. He was then appointed governor of New South Wales, an office which he held for four years. During that time he devoted himself most earnestly to the colony under his charge; he introduced new plants and breeds of animals, encouraged the reclaiming of waste lands, and even raised the status of the convicts by his wise measure of granting tickets-of-leave for good conduct. While in Australia he occupied himself in astronomical researches, erected a large observatory, and catalogued 7385 stars scarcely before known. The Royal Society awarded him their Copley medal for this work, *The Brisbane Catalogue of Stars.* After his return he resided chiefly at Makerstoun in Roxburghshire, where he had a large and admirably equipped observatory. Three volumes of his observations were printed in the *Transactions of the Royal Society of Edinburgh.* In 1836 he was made a baronet and K.C.B.; and in 1841 he became general. He received the degree of D.C.L. from Oxford, and was elected president of the Royal Society of Edinburgh after the death of Sir Walter Scott. Sir Thomas died on the 31st January 1860. He founded two gold medals for the encouragement of scientific research, one in the award of the Royal Society, the other in that of the Society of Arts.

BRISSON, MATHURIN JACQUES, a French zoologist and natural philosopher, was born at Fontenay-le-Comte, 3d April 1723. He studied for the church, but did not take orders, as his inclination led him towards the study of natural science. He became assistant to the celebrated Réaumur, and in 1756 published the first volume of his work on the animal kingdom, containing an account of the quadrupeds and cetacea. Of his other works on natural history the most important was the *Ornithologie*, 6 vols., 1760. After the death of Réaumur and the amalgamation of his museum with the royal cabinet, Brisson gave up the study of natural history and devoted himself to physical science. He obtained an appointment as professor in the college of Navarre, and was made instructor of the royal family in natural philosophy. Several text-books on physics were published by him, and were in considerable repute for a time, but his most important piece of work was the *Tables of Specific Gravities*, published in 1787. Brisson died in 1806.

BRISSOT, JEAN PIERRE, who assumed the name *De Warville*, a celebrated Girondist, was born of humble parents at Chartres in January 1754. He received a good education, and entered the office of a lawyer at Paris. His first works, *Théorie des Lois criminelles* (1781) and *Bib-*

liothèque philosophique du Législateur (1782) were on the philosophy of law, and showed how thoroughly Brissot was imbued with the ethical precepts of Rousseau. The first work was dedicated to Voltaire, and was received by the old *philosophe* with much favour. Brissot became known as a facile and able writer, and was engaged on the *Mercure*, on the *Courrier de l'Europe*, and on other papers, a connection with which was not creditable to him. He seems, indeed, to have sold his pen readily, and to have degraded himself by being associated with such men as De Morande. Ardently devoted, however, to the service of humanity, he projected a scheme for a general concourse of all the *savants* in Europe, and started in London a paper, *Journal du Lycée de Londres*, which was to be the organ of their views. The plan was unsuccessful, and soon after his return to Paris Brissot was lodged in the Bastille on an unfounded charge. He obtained his release after four months, and again devoted himself to pamphleteering, but had speedily to retire for a time to London. On this second visit he became acquainted with some of the leading Abolitionists, and attempted to set up in Paris a *Society of the Friends of the Blacks*. As an agent of this society he paid a visit to the United States, and returned just at the outbreak of the Revolution. Into this great movement Brissot threw himself heart and soul. He edited the *Patriote Français*, and being a well-informed, capable man, soon began to take a prominent part in affairs. In the National Assembly he leagued himself with the party, well known in history as the Girondists, but then frequently called the *Brissotins*. Of this party he was in many respects the ruling spirit. Vergniaud certainly was far superior to him in oratory, but Brissot was quick, eager, impetuous, and a man of wide knowledge. But he was at the same time timid and vacillating, and not qualified to struggle against the fierce energies roused by the events of the Revolution. His party fell before the "Moun-



Plan of Bristol.

tain;" sentence of arrest was passed against the leading members of it on the 2d June 1793. Brissot, persuaded by his friends, attempted to escape in disguise, but was arrested at Moulins. His demeanour at the trial was quiet and dignified; and on the 31st October 1793 he died bravely with his comrades. His works are numerous, but their interest was merely temporary.

See Mignet, *Revolut. Franç.*; Carlyle, *French Revolution*; and the numerous histories of the period, particularly Lamartine's *Histoire des Girondins*.

BRISTOL, a seaport town in the west of England, is situated in 2° 35′ 28″·6 W. long., 51° 27′ 6″·3 N. lat., 108 miles from London by road, 118 by Great Western Railway, 12 miles N.W. of Bath, and 8 miles inland from Bristol Channel, with which the port communicates by the Avon. That river, as well as the Frome which unites with it at the quay, runs through the city and forms the topographical division between Gloucestershire and Somersetshire, out of which provinces Bristol was constituted a distinct county in itself by a charter of Edward III. Its geological position is on the New Red Sandstone, which rises above the alluvial deposit of the rivers, while deep beneath these layers would be found the coal measures that succeed the millstone grit beds of the adjacent hills (*250 feet in height*) of Brandon and Kingsdown. The origin of the name is doubtful. Mr Seyer, the historian of Bristol, gives forty-two variations in the spelling of the word, and after showing attempted derivations from Brennus, the legendary founder of the town, Brictric, its Saxon lord, &c., finally decides for Brigstow, or Bridge-place, an etymology accepted by the author of *Words and Places*. "In fact, Bristow," says the Rev. John Earle, "is a condensed compound for *Tra-*

jectus ad Abonam;"[1] the place of the bridge at which the Avon was crossed. The vestiges of Roman occupation, however, on the site of the ancient city are scanty, and consist almost solely in the discovery at different spots of some coins of Severus and other emperors. *Caer Brito*, one of the thirty-three early cities of Britain mentioned by Nennius, is interpreted by Henry of Huntingdon (1154 A.D.) to mean Bristol. If (as now municipally) the name include the outlying heights of Clifton this interpretation may be adopted with less hesitation. 300 feet above the surface of the Avon, on both sides of the river, are Belgic British camps, with traces of superadded Roman work, one of which is comparatively perfect, a second of well-marked outline, while a third has been wantonly destroyed within the last two or three years. The existence of coins of Canute, of Harold I., of Hardicanute, of Edward the Confessor and of Harold II., of Bristol mintage, shows that the place was a centre of population under the Danes and Anglo-Saxons, but there is no positive mention of a Danish invasion except by Polydore Vergil, a 16th century historian.

The history of the town hardly begins till the subjugation of Gloucestershire by the Conqueror, in 1068. Bristol is not specially named, but there is no reason to believe that it offered any futile resistance to the sweeping tide of conquest. Early in the following year, three sons of Harold,—Godwin, Edmund, and Magnus,—resolving to reconquer the kingdom their sire had lost with his life, came at the head of fifty-two ships from Ireland up the Bristol Channel, and laying waste the coast on their way, sailed up the Avon to Bristol. Here they were sharply repulsed by the townsmen, and afterwards more thoroughly routed by Geoffry Mowbray, bishop of Coutance, nephew to the famous Tancred the crusader (*Biog. Univers.*) Though Bristol is mentioned in *Domesday*, Bristol Castle is not,

Obverse. Reverse.

Corporation Seal (Motto: *Virtute et Industria*).

but appears first in history in connection with the constableship of the martial prelate just named, who held the fortress for Robert duke of Normandy against William Rufus. When the king had crushed the insurrection and driven the rebel churchman out of the realm, he granted the royalty, or Honour of Gloucester, which included Bristol, to his kinsman Robert Fitzhamon, who thus became feudal chief of the territory Fitzhamon's daughter, Mabel, marrying Robert earl of Gloucester, natural son of Henry I., that noble, upon the death of his father-in-law, became lord of the tower and town of Bristol. He rebuilt the castle, which soon received as captive within its walls Robert duke of Normandy, who was afterwards removed to Gloucester's stronghold at Cardiff. The red earl of Gloucester, as he was called, was the most powerful baron of his age; and among his successes in war, was the capture of king Stephen at the battle of Lincoln, who was brought to Bristol, and, like Curthose, imprisoned in the castle, where he remained in chains till exchanged for Gloucester himself, who in his turn was defeated and captured by Stephen's queen at Winchester. Earl Robert died in 1147 and was succeeded by William his son, whose daughter, Avisa, marrying John earl of Moreton, afterwards king John, the town and castle of Bristol became an apanage to the crown, and as such it continued to the time of Charles I. John was as many as nineteen times at Bristol, the neighbouring forest of Kingswood, which stretched 14 miles square to the east of the city, no doubt resounding frequently to the cry of his hunt.

Henry III., upon the death of John, came for security to Bristol Castle, when he permitted the town to choose a mayor after the manner of London; and in like usage that the mayor of London was sworn before the constable of the Tower, so here he was directed to be sworn before the constable of the castle of Bristol, each fortress being distinct from its respective city. This feudal custom was continued here until Edward III. conceded, among other chartered benefits, that the new mayor should take oath of office before the retiring mayor in the Guildhall of Bristol in the presence of the commonalty. Other privileges from the same monarch were the establishment here of the wool-staple, and the empowering of the mayor and sheriff to elect from time to time forty of the "better and more honest" men of the town, as a council to rate and levy taxes, &c., which common council, in nearly the same form as instituted, is yet maintained.

Richard II. confirmed all the grants of his predecessors, and directed that the steward and marshal and clerk of the royal household should not sit in the town of Bristol, as before had been granted to the city of London. In 1387 the king was at Bristol castle "with," says Froissart, "the queen and all the ladies and damsels of her court," having accompanied thus far his favourite, De Vere, towards Ireland. Two years later Henry Bolingbroke, with his vast northern army, surrounded the walls of this important western city which immediately surrendered. After four days' siege the castle also capitulated, one of the terms of the treaty with the duke of York, agreed to by its governor, Sir William Courtnay, being that Lord Scrope, earl of Wilts, Sir Henry Green, and Sir John Busbie, who were within its walls, should be delivered into the hands of the duke of Lancaster. In Shakespeare's *Richard II.* is a scene wherein Bolingbroke denounces these minions of the falling cause, and orders Lord Northumberland to see them despatched. They were beheaded in the centre of the town, where then stood the high cross. Only a few years since an unsuccessful attempt was made in the House of Lords to revive the peerage of Wilts, which included the right to wear a kingly crown in the Isle of Man, that peerage having been dormant from the time Sir William Scrope here lost his head. In 1408 Lord Spencer, another adherent of the ruined dynasty, was also executed at the same spot.

By a charter of Henry VI. the town of Bristol, with its gates, ditches, walls, and markets, was farmed to the mayor and burgesses for sixty years at the annual rent of £102, 15s. 6d. to the king's household, and £57, 4s. 6d. to the abbot of Tewkesbury and to the castle. This yearly fine of £160 was granted by Edward IV. to Elizabeth his queen consort Richard III. released £60 of this rent, and the remainder was redeemed in the reign of Charles I.

The doctrines of the Reformation were preached here by Tyndale, Cranmer, and Latimer. The issue of the dissolution of religious houses, of which thirteen encircled the outer walls of the city, was the erection here of a bishopric (1542) by the conversion of the abbey church of Austin canons into a cathedral. It has singularly escaped the notice of every writer that the episcopate was refounded in 1551, by power of letters apostolic directed by Pope Paul IV. to Cardinal Pole; a MS. copy of the original Bull is in the Bristol Museum. The transitional epoch from the Papal to the Protestant faith was stained here by the

[1] *Arch. Inst. Jour.*, vol. xviii. 350.

blood of five martyrs; to which number we may add a sixth, James Duke, who belonged to Bristol, but suffered in Kent. About the beginning of autumn 1559 "the church wardens of all the churches of Bristow," says an unpublished chronicle noticed below, "and some of the ministers, brought forth their roods and other images, which were in their churches, to the High Cross where they were burnt."

The detachment of the castle from the county of Gloucester, and its grant to and incorporation with the town of Bristol by Charles I. (1629) at the request of Henrietta Maria, was another important surrender from the Crown, but the charter cost the city £949, and the castle was to be holden at a fine of £40 yearly. As London was called the King's Royal Chamber, so Bristol was called the Queen's Royal Chamber; but courtly favours were all practically cancelled by the infliction of the ship-money tax. By the king's writ (of October 20, 1634), £6500 was charged on Bristol for this impost, and there were further taxations in successive years. The payment of these assessments became at length so dilatory as to draw down (1638) a sharp reprimand from Government upon the mayor, with the threat,—"if you give not his majesty better satisfaction we shall take a course to make you sensible of your duty" (*Cal. State Papers*).

The hurtful interference with the trade of the place (such as the limitation in the manufacture of soap to 600 tons yearly, which article had been from the 12th century, and is even now, one of the chief of Bristol productions) prepared the way for the easy admission of Col. Essex and his troops, when in 1643 he presented himself before the gates of the city. The Parliament held the place from 5th December 1642 to 26th July in the following year, when Prince Rupert, with his cavaliers, surrounded the walls, and storming at all points frightened the governor, Col. Fiennes, who had succeeded Essex, into capitulation. In August 1645 the city was assaulted by Fairfax and Cromwell, and on the 20th day of the siege, it having been heard that the king was in full march upon the west, a storm was decided upon, and after a sharp assault on the 11th of September, Rupert surrendered. "We had not killed of ours in the storm," says Cromwell, "nor in all this siege, two hundred men. He who runs may read that all this is none other than the work of God. He must be a very atheist that doth not acknowledge it." Ten years later the castle was demolished by order of the Protector. The history during the next century and a half is unmarked by any very striking events. The rise of Nonconformity; the persecution of the Quakers, of whom 103 were in Bristol prisons at the accession of Charles II.; the visit of the sanguinary Jefferies on his famous western assizes, when six persons were condemned and executed on Redcliff hill, are some of the chief phases and incidents during this period. In 1684 was given the charter granting that "the citizens and inhabitants of Bristol and their successors hereafter for ever may and shall be a body corporate in deed, fact, and name, by the name of *the Mayor, Burgesses, and Commonalty of the City of Bristol*, with a common seal." In 1685 James II. stopped here on his way to Sedgemoor; and he again visited Bristol in the following year, and was handsomely entertained. The bishop of Bristol at the time was Lake, one of the historical seven, who was succeeded by Trelawny, another of the seven. The greatest merchant in Bristol at this period was Edward Colston, whose profuse benevolence has made his name splendid among the citizens. In the foundation of schools and almshouses, repairs of churches, &c., he gave £70,695, a vast sum in these days. He died in 1721. Three influential societies instituted to his memory yearly assemble at public dinners, where they collect alms for lying-in women, for apprenticing boys, &c. Up to the end of 1874 the amounts collected from their commencement by these—the Dolphin, Anchor, and Grateful societies—have attained an aggregate of £118,013. At the election of 1774 Bristol was represented in the person of the famous Edmund Burke, but his policy did not please all his constituents, and he consequently lost his seat here for the next Parliament. His defensive speech on the hustings of Bristol "is one of the most convincing pieces of popular oratory on record." The Bridge Riots of 1793 and the Reform Riots of 1831 are dark spots on the history of *Bright-stow*, or Bright-place, as old Fuller interpreted the name. The former were the result of opposition to the prolonged impost of toll which it was prevalently understood was to cease by a certain day. About forty persons lost their lives by a charge of the military on this occasion. The Reform Riots have been called "The Bristol Revolution," but were simply a revolt of the lowest stratum of society, in whom mania for plunder superseded all political principle. Forty-five houses, the bishop's palace, and the prisons were burnt to the ground; twelve of the rioters were killed by the soldiers, several perished in their own fires, four were hanged, thirty were imprisoned; the colonel of the troops committed suicide, and the city was mulcted in £68,208 damages. The next year the cholera visited the people, when 626 died of the malady.

The nautical enterprise of Bristol has been worthy of a place that "seems to swim on the waters" and struck the eye of Pope the poet as having its streets full of ships. Some remarkable voyages from the port are recorded, but perhaps none more memorable than that of Sebastian Cabot in 1497, who was the first Englishman (for he was born in Bristol) who landed in America, and the earliest to discover that portion of the continent now called the United States, and thereby to secure its English colonization. The notice in a hitherto unpublished local chronicle is as follows:—"This year (1497), on St John the Baptist's day, the land of America was found by the merchants of Bristowe in a ship of Bristol called the 'Matthew,' the which said ship departed from the port of Bristowe the 2d of May, and came home again 6th August following."[1] A Bristol privateer brought home from Juan Fernandez the real Robinson Crusoe. The saucy "Arethusa" frigate, celebrated for naval daring by Dibdin in song and by Capt. Chamier in romance, was built at and belonged to Bristol. The first steamboat built and fitted at the same port was the "Wye," in 1827. Bristol was the first city in the kingdom that established regular steam communication with the United States, the first voyage having been made by the "Great Western" in 1838. This vessel was built at Bristol at a cost of £60,000. The "Great Britain" and the ill-fated "Demerara" were also built here, the former costing £120,000.

The creation of Bristol a free port in 1848 has resulted in great increase of trade. The tonnage of foreign vessels (exclusive of Ireland) with cargoes entering the town, was in 1846, 100,722; in 1873, 411,014; in 1874, 432,940. The quantity of grain of all kinds imported between April 1874 and April 1875 was 1,062,007 quarters; of wine, 7459 pipes; of timber, 34,740 tons; of sugar, 83,858 tons. With respect to the shoe manufacture, in January 1657, leave was given by Government to Mr Ellis of Bristol, to send 1000 dozen of shoes to Barbadoes, and another 1000 dozen in December. The combined shoe trade now employs 5000 hands, one firm, Derham's, alone paying in wages £50,000 per annum. Fry's chocolate and cocoa works occupy between 500 and 600 hands. The soap trade engages about 400 hands. In the Great Western Cotton Works about 1500 are employed; in the stay trade 2000 people.

Bristol stands fourth of all the seaport English towns in the amount of customs revenue received. The gross amount in 1864

[1] These important dates have not (at least the two latter) till now been published. They are from an ancient manuscript for several generations in possession of the Fust family of Hill Court, Gloucestershire, the "collations" of which are now (1876) in the keeping of Mr William George, bookseller, Bristol.

was £1,103,000; this had increased in 1866 to £1,174,181, and decreased in 1873 to £941,679. The inland revenue received in the year 1874-5 was £467,091.

The boundaries of the city within its ancient limits comprised 755 acres, and the districts added by the Municipal Act (5 and 6 Wm. IV.) contained 4124 acres, making a total of 4879 acres. The population of the ancient city and of these districts according to the census returns of the present century has been as follows:—

Year.	Ancient City.	Added Districts.	Total.
1801	40,814	20,339	61,153
1811	46,592	24,891	71,483
1821	52,889	32,219	85,108
1831	59,074	45,334	104,408
1841	64,266	60,880	125,146
1851	65,716	71,612	137,328
1861	66,027	88,066	154,093
1871	62,662	119,890	182,552

The entire rateable value in 1861 was £508,988; in 1871, £719,983. The circuit of the municipal boundaries is 15 miles. The town is divided into 10 wards, returning 48 members to the town council, selected by the burgesses, with 16 aldermen, chosen by the council,—64 members in all. There are 30 acting justices of the peace, appointed by the lord chancellor, the mayor being chief magistrate. Bristol returns two members to Parliament.

The amount of the poor-rate levied from house to house by the churchwardens in 1696 (the year before the Incorporation Act) was £2145. At the present time it is £36,000, in addition to the other rates. The rateable value for poor-rate in 1874 was £759,441, at about 1s. 9d. in the pound, or £66,451, 1s. 9d. The local taxation in 1874 was an average total of 5s. 4½d. in the pound. The amount paid in 1874, not including shipping dues, was £187,573.

Architecture and Public Buildings.—To a few great baronial families—the earls of Gloucester, the Berkeleys, and the Gaunts—in its early history, and to a few great merchants—the Canyngs, the Shipwards, and Framptons—in its later career, the architecture, principally ecclesiastical, for which Bristol is famous, has been due. Though much of this has been destroyed, much remains. Robert Fitzhamon's Norman tower of St Peter, the oldest church tower in Bristol, still presents its massive square to the eye. Of the castle of Robert earl of Gloucester, the walls of which were 25 feet thick at the base, nothing remains, but there still exist some walls and vaults of the later stronghold, including a fine Early English cell. The grand nave of St James's church, which the same noble also erected, and wherein he was buried, yet stands. Of Fitz Harding's abbey of Austin canons, founded in 1142, the stately entrance gateway, with its sculptured mouldings, has hardly been injured by seven centuries' exposure to rudeness of weather and greater rudeness of men. The abbot's gateway, the vestibule to the chapter room, and the chapter-room itself, which is carved with Byzantine exuberance of decoration, and acknowledged to be one of the grandest Norman rooms in Europe, are also perfect. The Early English lady chapel, the geometrical east window, and the side aisles in their singular design and beauty are other specific features of the abbey church, now the cathedral. The nave just added to the 14th century structure has cost to the present time £40,000. Besides the canopied tombs of the Berkeleys with their effigies in chain mail, and similarly unique tombs of the crosiered abbots, there are memorials to Bishop Butler, to Sterne's Eliza, and to Lady Hesketh the friend of Cowper, who are all here interred. Also there is here Mason's touching epitaph: "Take holy earth, &c.," and monuments by Baily and Chantrey. All Hallow's church has a modern Italian campanile, but is in the main 15th century, with the retention of four Norman piers in the nave; and is interesting from its connection with the ancient guild of calendars, whose office it was "to convert Jews, instruct youths," and keep the archives of the town. Theirs was the first free library in the city, possibly in England. The records of the church contain a singularly picturesque representation of the ancient customs of the fraternity. The chapel of the Gaunts is 13th and 14th century, and presents with its rich panelled roof, pictured windows, carved tabernacles and tombs, a concentration of mediæval Gothic art. Of St Michael's, St Thomas's, and Werburgh's, only the towers (15th century) are preserved of the old structures. St Nicholas church is modern, on a crypt of the date 1503 and earlier. Temple church, with its leaning tower, 5 feet off the perpendicular, retains nothing of the Templars' period, but is a fine building of the Decorated and following style. The tower and spire of St John's (15th century) stand on one of the gateways (same date) of the city. This church is a parallelogram, without east or west windows or aisles, but is built upon a groined crypt. St Mary le Port and St Augustine the Less are churches of the Perpendicular era, and not the richest specimens of their kind. St Philip's has an Early English tower, but its external walls and windows are for the most part debased Perpendicular. St Stephen's church, built between 1450 and 1490, is a dignified structure, but is chiefly interesting for it fan-traceried porch and stately tower, the latter being hardly surpassed by any parish tower in England. It was built entirely by the munificence of John Shipward, a wealthy merchant. The crown of Bristol architecture is, however, the church of St Mary Redcliff, which for grandeur of proportion, and elaboration of design and finish, is entitled to stand in the selectest rank of English parish churches, and might be compared with a lesser cathedral. It was built for the most part in the latter part of the 14th century by William Canyng, but the sculptured north porch, which has cost £2535 to restore, is externally Decorated, and internally Early English. The fine tower is also Decorated. The spire just added has cost £5500. The restoration of the church has extended over thirty years, at an expense of £40,000.

Among conventual remains, of the Dominican priory there exist the Early English refectory and dormitory, the latter comprising a row of fifteen original windows and an oak roof of the same date; and of St Bartholomew's hospital there is a double arch, with intervening arcades, also Early English. The small chapel of the Three Kings of Cologne, and Holy Trinity Hospital, both Perpendicular, comprise, with the remains of the Austin canonry attached to the cathedral, nearly the whole of the monastic relics.

There are many good specimens of ancient domestic architecture,—notably some arches of a grand Norman hall and some Tudor windows of Colston's house, Small Street; Canyng's house, with good Perpendicular oak roof; and St Peter's Hospital, Jacobean and earlier.

In all there are 42 Episcopal churches, and 81 dissenters' chapels,—the latter comprising 10 Baptist, 19 Congregationalist, 11 Wesleyan, and 5 Roman Catholic (besides 6 convents). The Exchange is a quadrangular colonnade, with a noble frontage by Wood of Bath. The Guildhall is modern Tudor Gothic. The Bristol Museum and Library is a fusion of the two leading philosophical and literary societies of the district, a spacious building in the Venetian Gothic style, having been built for their joint purposes. The geological collection is among the best provincial collections; the library (40,000 vols.) is the largest in the west of England. There is also a free library, under the Act.

Among the endowed public schools are (1), the Cathedral school, founded 1542, and Cathedral college (1876); (2), the Grammar school, which has secured a high position, and has right of presentation to two university scholarships; (3), Queen Elizabeth's Hospital for 200 boys, who are educated and clothed free; (4), Colston's school; (5), Baptist college for educating young men for the Baptist ministry; (6), Redmaids' school for 120 girls, free. A Girls' Reformatory school, the first established under the Act, owes its origin to Miss Mary Carpenter, who is still lady superintendent. Up to

the end of 1874 there have been in this school 417 girls, of whom 66 were still there. During the last 4 years 87 have left, of whom 64 were earning a creditable living. The Royal Infirmary administered in 1874 to 2792 in and 23,163 out patients; the General Hospital to 1404 in and 13,512 out patients. Muller's Orphan House comprises five buildings, which have cost £115,000. The average number of inmates is 2000 children and 120 officials. The average cost of each child, exclusive of salaries, is £13 a year. Nearly £600,000 has been given for the furtherance of the work since it was begun in 1836. There is a school-board in Bristol, with 20 attached schools, and 113 schools under inspection.

See Barrett's *History of Bristol*, 1789; Seyer's *Memoirs of Bristol*, 1821; Dallaway's *Antiquities of Bristow*, 1834; Evans's *Chronological History of Bristol*, 1824; Bristol vol. of *Brit. Archæolog. Inst.*; Taylor, *Book about Bristol*, 1872; *Bristol and its Environs*, 1875.

BRISTOL, a town of the United States, the capital of a county in Rhode Island, is situated on a peninsula between Narraganset Bay and Mount Hope Bay, 16 miles S.E. of Providence by rail. Its trade and manufactures are considerable, but it is chiefly important as a summer watering-place. There is direct steamboat communication with Providence and New York. During the War of Independence the town was nearly destroyed by the English. Population in 1870, 5302.

BRITANNIA. The history of Britain begins with the invasion of Julius Cæsar, 55 B.C. Cæsar is the first Roman writer who mentions Britain; before him we have only a few short notices in Greek writers, who appear to have known but little about the country. The earliest notice of Britain is in Herodotus (450 B.C.), who mentions the *Tin Islands*, only to confess his ignorance about them. By the Tin Islands are probably to be understood only the Scilly Isles and Cornwall, which are said to have been known to Phœnician traders some centuries before the Christian era.

More important is a passage in Aristotle, who, writing a century later than Herodotus, is the earliest writer who mentions the British Isles by name. The passage is in the *De Mundo*, c. 3,—"Beyond the pillars of Hercules (Straits of Gibraltar) the ocean flows round the earth, and in it are two very large islands called British (βρετανικαὶ λεγόμεναι), Albion and Ierne, lying beyond the Keltoi." The application of the name Britannia, to denote the larger island, is first found in Cæsar.

The etymology of the name Britannia is uncertain. Of the numerous derivations which have been proposed the most generally adopted is that which connects the word with a root *brith* (*variegatus*), in supposed allusion to the British practice of staining the body with woad; but this is not to be considered as perfectly satisfactory.

The earliest inhabitants of Britain concerning whom we have any certain knowledge are the Celts, who formed the vanguard in the great westward migration of the Indo-European or Aryan nations; but it seems certain, from the evidence of remains found in the country, that the Celts were preceded in their occupation of it by a non-Aryan race.

The Celtic family is divided into two branches—the Gaelic and the Cymric. To the former belong the Irish and the Highlanders of Scotland, to the latter the Welsh and the inhabitants of Britanny, and to these may be added the ancient Gauls, the remains of whose language seem to prove without doubt that they belonged to the Cymric and not to the Gaelic branch.

Of the Celtic inhabitants of Britain nothing is known before the time of Cæsar, whose account of them is the earliest which we possess. Somewhat abridged it is as follows:—

"The interior of Britain is inhabited by a race said to be aboriginal, the coast by invaders from Belgium, who having come over for the sake of spoil have settled in the country. For money they use either copper or pieces of iron of a certain weight. Tin is found in the interior of the country; iron on the coasts, but the quantity is small; copper is imported. The timber is of the same kinds as in Gaul, except the beech and the fir. The climate is more temperate than in Gaul, the cold being less severe."

After a short geographical description of the island, Cæsar proceeds to speak of the inhabitants—

"By far the most civilized are the inhabitants of Cantium (Kent); they do not differ much in their customs from the Gauls. The inhabitants of the interior do not for the most part sow corn, but live on milk and flesh, and clothe themselves with skins. All the Britons stain themselves with woad, which produces a blue colour, and gives them a more formidable appearance in battle. They wear their hair long, and shave every part of the body except the head and the upper lip. Ten or twelve have wives in common. (Cæs., *B. G.* v. 12–14).

Nothing is here said as to the religion of the Britons; and we are obliged to turn for information on this head to Cæsar's account of Druidism in Gaul. We are justified in so doing by Cæsar's statement that the religious system of the Gauls was devised in Britain, and that it was still the custom for those who wished to become thoroughly versed in it to go thither for the sake of instruction. Having said that besides the common people, who are of no account and are little better than slaves, there are in Gaul two orders,—the Druids and the Knights,—Cæsar goes on to give an account of the former—

"The Druids are engaged in matters of religion, and have the care of public and private sacrifices. They are the arbiters in almost all disputes, public and private, and assign rewards and punishments. Whoever refuses to abide by their decision is excluded from the sacrifices, and thereby put outside the pale of the law.

"The Druids are exempt from military service, and from the payment of taxes. Their chief doctrine is that souls do not perish with their bodies, but are transferred after death to other bodies."—(*B. G.*, vi. 13–14.)

These are the leading points of Cæsar's short account of the Druids, which is the earliest we possess, and is the main foundation on which has been raised the elaborate Druidic system of later writers.

Politically, Britain consisted of a number of independent tribes united in a federation of the loosest kind, in which the lead was taken by the tribe which happened at any time to be the most powerful.

The Britons appear to have kept up a tolerably close intercourse with the Continent. They are first mentioned by Cæsar as sending aid to the Veneti (a Gaulish tribe whose name is preserved in that of the present town of Vannes), in their revolt against the Roman power. This was in 56 B.C.; and in the following year Cæsar resolved on an invasion of Britain, partly influenced, no doubt, by the desire of taking vengeance for the help afforded by the Britons to his enemies the Veneti. C. Volusenus having been previously sent to examine the British coast, Cæsar himself set sail from Portus Itius (probably Wissant, between Boulogne and Calais) on the night of the 26th of August 55 B.C., taking with him two legions. The opposite coast was reached early on the morning of the following day, and after a sharp struggle a landing was effected apparently somewhere near Deal. Slight resistance was now offered by the Britons, to whom peace was granted on easy terms, and the Romans hastened back to Gaul.

Early in the following summer Cæsar again started from Portus Itius, this time with a force of five legions and a corresponding body of 2000 cavalry, and landed on the coast of Britain at the same place as in the previous year. Leaving a small force to protect the ships he advanced twelve miles inland to the River Stour before meeting with the enemy. Cassivellaunus, chief of the country to the north of the Thames, had been chosen by the Britons as their general-in-chief, and under his command they for a time presented a fierce resistance to the invaders, but they were unable to withstand the steady onset of the Romans, and Cæsar soon reached and took by storm Cassivellaunus's capital. The site of this city is now unknown, but it has been

conjectured with some probability to have been Verulamium (St Albans). Cassivellaunus now sued for peace, and after receiving hostages and fixing the amount of the tribute Cæsar left the country before the end of the summer. No garrison was left behind to secure the Roman conquests, which were thus practically relinquished. For nearly a hundred years after this date the history of Britain is almost a blank. The Emperor Claudius, on his accession to the empire in 41 A.D., determined to carry out Augustus's intention of exacting the British tribute; accordingly (43 A.D.) Aulus Plautius was sent to Britain with a force of four legions, and having landed without opposition, he advanced to the northern side of the Thames, and there awaited the emperor's arrival. Plautius was soon joined by Claudius, who at once led his army against the Britons, over whom he gained a complete victory, immediately after which he returned to Rome, leaving Plautius to secure his conquests.

The war was now carried on in the west between the Roman general Vespasian, who afterwards became emperor, and the Silurian chief Caractacus (Caradoc). After a struggle of nine years Caractacus at length, in 51 A.D., met with a decisive defeat at the hands of P. Ostorius Scapula. Having fled for refuge to Cartismandua, queen of the Brigantes (a tribe occupying the district between the Tyne and the Humber), he was betrayed by her to the Romans, by whom he was taken to be led in triumph through the streets of Rome.

Ten years after this Boadicea, queen of the Iceni, a tribe occupying the present counties of Norfolk and Suffolk, took advantage of the absence in Mona (Anglesey) of the Roman prefect, Suetonius Paullinus, to excite her people to revolt. The Roman colony of Camulodunum (Colchester) was taken and sacked, and the rebellion soon seemed seriously to threaten the Roman power. Suetonius, however, hastened up from the west, and in a single battle, fought near London, inflicted a decisive defeat on the Britons, following up his victory by a massacre in which 80,000 Britons are said to have perished. Boadicea poisoned herself to avoid falling into the hands of the Romans. The spirit of insurrection was now completely crushed; a milder policy was adopted by the successors of Suetonius, and Roman civilization began rapidly to spread over the country.

The next event of importance is the arrival of Agricola as governor of Britain in year 78. Agricola's first task was to complete the subjection of the Ordovices (North Wales), and this having been speedily accomplished, he adopted, with great success, a policy of conciliation. He encouraged education and building, and succeeded in introducing Roman dress and manners among the Britons. This, says Tacitus, they in their ignorance called civilization, though it was but a part of their slavery. In 79 Agricola attacked the Brigantes, and reduced the country betwen the Humber and the Tyne. During five years he continued to advance further north, and in 84 he defeated a Caledonian chieftain, named Galgacus, in a great battle, the site of which it is impossible to fix, but it was probably not far from the eastern coast of Scotland at some place north of the Tay. Agricola was now recalled to Rome, and no attempt was made to maintain the conquests north of the line of forts which he had built between the Forth and the Clyde.

The remainder of the period of the Roman occupation is for the most part uneventful. In 120 the Emperor Hadrian visited the country, and built a rampart between the Tyne and the Solway Frith, in order to check the inroads of the northern tribes. In 139 a wall, called the wall of Antonine, in honour of the emperor Antoninus Pius, was built by the prefect Lollius Urbicus along the line of Agricola's forts between the Forth and the Clyde. In 207 the Emperor Severus came to Britain in order to lead in person an expedition against the Caledonian tribes. He advanced far into Caledonia, driving the enemy before him but never meeting them in a pitched battle. No substantial advantage was gained in this desultory war, which cost the lives of 50,000 Roman soldiers. Severus built a new wall along the line of Hadrian's rampart, and died at York in 211.

The Roman empire was now in a state of decay, and its weakness offered great temptations to distant officials to seize the supreme power for themselves. About 287 the title of emperor was assumed by a man of low birth named Carausius, a native of Menapia (the district between the Scheldt and the Meuse), who had been appointed to the command of the fleet stationed in the English Channel for the purpose of protecting the coasts of Britain and Gaul from the Frisian pirates, and whose conduct in that position had been such as to draw from the emperor Maximian an order for his death. After a successful reign of seven years, in the course of which his independence was acknowledged by Maximian, Carausius was assassinated by his chief officer Allectus, who in his turn usurped the imperial title during three years, at the end of which Britain was regained for Rome by Constantius Chlorus (296). Constantius afterwards led an expedition into Caledonia, and died at York in 306.

Soon after this date the Picts and Scots begin to be heard of as invading the Roman province from the north. The Scots, who occupied the western part of Caledonia, belonged to the Gaelic branch of the Celtic family, and had crossed over from Ireland, bringing with them the name which was afterwards bestowed on their new home. The question as to the origin and the language of the Picts is one which has been long under discussion, and still seems far from a definitive settlement. The Picts are now, however, generally admitted to have been a Celtic race, and the evidence of language, as far as can be judged from the very few Pictish words, chiefly proper names, which have been preserved to us, seems to indicate the Cymric rather than the Gaelic as the branch to which they belonged. (For further information on this point see Garnett, *Philological Essays*, and Skene, *The Four Ancient Books of Wales*. Garnett holds the view that the Picts were a Cymric race; Skene believes them to have belonged to the Gaelic branch of the Celtic family.)

In 367 the Picts and Scots overran the whole country as far south as London. Theodosius, father of the emperor of that name, was sent against them, and in two campaigns he succeeded in driving them back beyond the wall of Antonine. The district thus regained between the walls of Hadrian and of Antonine was named Valentia, in honour of the reigning emperor Valentinian. This, however, was only a momentary check, and the new province was soon lost.

In 383 the title of emperor was assumed by Maximus, a native of Spain, who had served under Theodosius in the Pictish wars. Maximus took a large army of Romans and Britons into Gaul and was recognized by Theodosius and Valentinian as sole emperor over Britain, Gaul, and Spain. Five years later he invaded Italy, but was taken and beheaded at Aquileia in 388. The army never returned to Britain, which was thus left weaker than ever. In 396 a single legion was sent by Stilicho, and the Picts were once more driven back. In 407 three successive emperors—Marcus, Gratian, and Constantine—were set up in Britain, the last of whom followed the example set by Maximus, and carried the army into Gaul, leaving Britain again helpless against the northern invaders. In 410 the Roman occupation of Britain was formally terminated by a letter addressed by the emperor Honorius to the cities

of Britain, in which he told them that they must henceforth be their own defenders.

Britain first became a Roman province in the reign of the emperor Claudius, 43 A.D. It was governed by a single prefect until the reign of Severus, who divided the province into two parts, called Britannia Superior and Britannia Inferior, each governed by a prefect. In the division of the empire into four prefectures in the reign of Diocletian, Britain formed part of the prefecture of Gaul, and was governed by an officer called the *vicarius*, residing at York. The country was subdivided into four provinces, each governed by a prefect:—

1. *Britannia Prima*, the district south of the Thames.
2. *Britannia Secunda*, the district south of the Dee and west of the Severn.
3. *Flavia Cæsariensis*, east of the Severn.
4. *Maxima Cæsariensis*, the district between the Humber and the Tyne.

To these was added as a fifth province the district of *Valentia*, conquered by Theodosius in 368, but it appears to have remained but a short time in the possession of the Romans.

Our knowledge of the events of the two centuries succeeding the close of the Roman occupation of Britain is rendered most uncertain by the absence of contemporary records. The accounts given by later writers, British and Saxon, cannot be relied upon for more than the barest outline, which may be accepted in so far as it is found to be consistent with the visible results of the events of this period.

The paternal character of the Roman rule had left the Britons at its withdrawal enervated and helpless, and utterly unable to cope with the Picts, who now began to press heavily on them. Having in vain appealed for help to the Romans, the Britons applied to the Teutonic rovers who had since the later years of the Roman period been in the habit of plundering the eastern coast. Accordingly, the three tribes of Angles, Jutes, and Saxons came over, and with their assistance the Picts were driven back into their own territories. The Saxons, however, still continued to arrive in large numbers, and soon finding the occasion of a quarrel, they combined with the Picts against the Britons, and proceeded to overrun the country, driving the Britons before them into the west. The first Teutonic kingdom in Britain was that of Kent, founded in 449; and at the end of two centuries we find the Saxons in firm possession of the greater part of the country, and the Celtic tribes occupying only the extreme west. Of Arthur, the hero of the Welsh account of this period, it is impossible to speak with any certainty Although he is unknown to the Saxon chronicle, it seems unnecessary to deny his existence, and it is certain that no part of the south-western district of England, which is generally supposed to have been the scene of his exploits, was conquered by the Saxons until after the time of his alleged victories. An attempt has lately been made (see ARTHUR) to show that the scene of Arthur's victories is to be laid in the south of Scotland, and not in the west of England. The question is one which hardly seems capable of a satisfactory settlement. For the subsequent history see ENGLAND.

See *Monumenta Historica Britannica*, 1848; Camden's *Britannia*; W. B. Jones, *Vestiges of the Gael in Gwynedd*; Merivale, *History of the Romans under the Empire*; Burton, *History of Scotland*, vol. i. (A. W. K. M.)

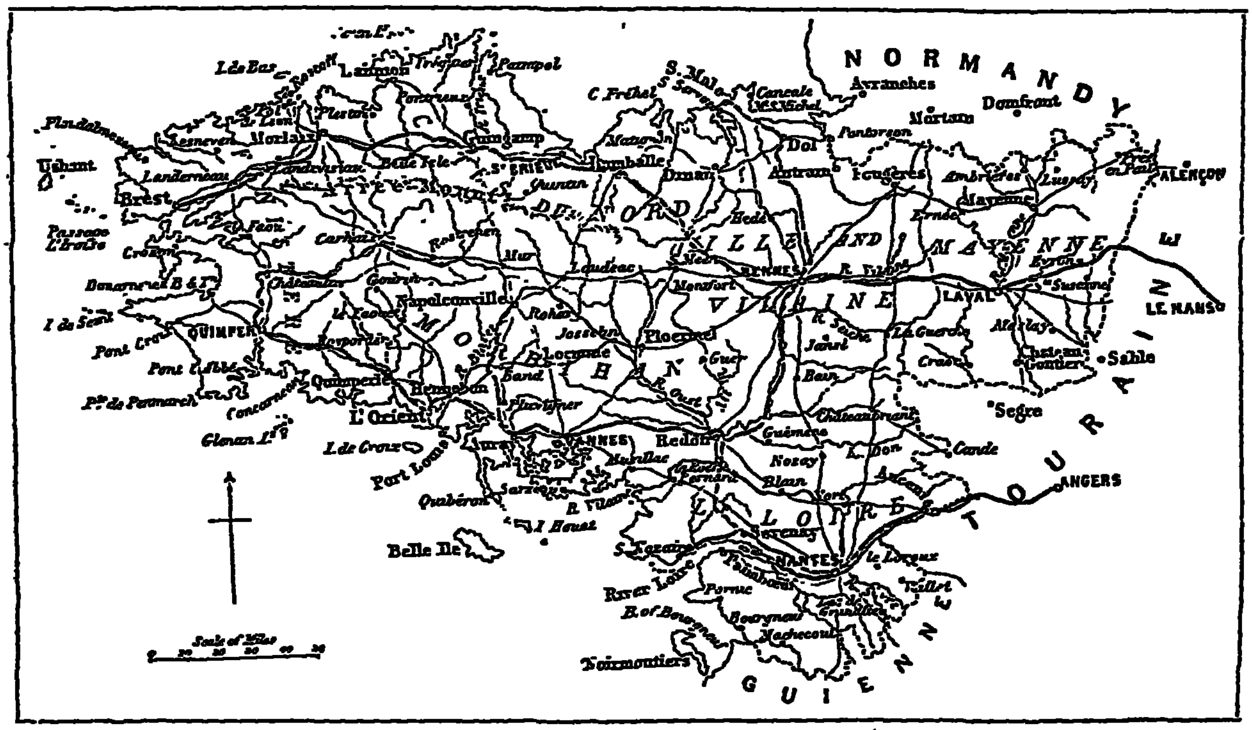
BRITANNICUS, son of the emperor Claudius, and of his third wife Messalina, was born probably 42 A.D., though the exact date cannot be determined. He was originally called Claudius Tiberius Germanicus, and received the name Britannicus on account of the conquests made in Britain about the time of his birth. Till 48 A.D., the date of his mother's execution, he was looked upon as the heir to the imperial dignity, but Agrippina, the new wife of Claudius, soon persuaded the feeble emperor to pass him over and adopt her son by a previous marriage, Lucius Domitius, known later as Nero. After the accession of Nero, Agrippina, whose lover, Pallas, had been banished, threatened to stir up revolt against the new emperor, and excited his fears against Britannicus. Poison was administered to the young prince, at first without effect, but a stronger dose given at the banquet table was instantaneously fatal. The murdered boy, for he had barely completed his fourteenth year, was buried on the evening of the day in which he died. The pile was erected on the Campus Martius amidst a deluge of rain, which washed the plaster and paint from the livid and distorted face of the corpse.

BRITISH COLUMBIA. See COLUMBIA, BRITISH.

BRITTANY, or BRITANNY (French, *Bretagne*), an ancient province and duchy of France, consisting of the north west peninsula, and nearly corresponding to the departments of Finistère, Côtes-du-Nord, Morbihan, Ille et Vilaine, and Lower Loire. It is popularly divided into Upper or Western, and Lower or Eastern Brittany. While it is not a mountainous country, none of the elevations much exceeding 1200 feet, it is remarkable for the extreme ruggedness of its physical features, especially along the coast and towards its seaward extremity. There are vast tracts of desolate moorland broken only by the melancholy monuments of a forgotten time, and gloomy water-courses worn deep into the stony strata. Elsewhere, however, beautiful valleys and romantic glens are traversed by full-flowing rivers. Agriculture is in general in a rather backward condition, though here and there there are signs of enterprise. Flax and hemp are largely grown; and in the more fertile districts excellent crops of the cereals are obtained. Bees are almost universally kept, and are often objects of a kind of affection. Pasture is abundant throughout the country, and the dairy produce forms a very important item in the food of the people. Industrial pursuits, except in a few seaport towns, which are rather French than Breton, have hitherto received but little attention. The Bretons are by nature conservative. They cling with almost equal attachment to their local customs and their religious superstitions. It was not till the 17th century that paganism was even nominally abolished in some parts, and there is probably no district in Europe where the popular Christianity has assimilated more from earlier creeds. Witchcraft and the influence of fairies are generally believed in, and charms and antidotes are trustfully resorted to. Part of this superstitious tendency may, no doubt, be attributed to the influence exerted on the minds of the people, not only by the strangeness of their natural environment, but also by the frequency of megalithic monuments, whose origin they cannot explain, for nowhere are these monuments so numerous and varied. The costume of both sexes is very peculiar both in cut and colour, but varies considerably in different districts. Bright red, violet, and blue are much used, not only by the women, but in the coats and waistcoats of the men. The reader will find full illustrations of the different styles in Bouet's *Breiz-izel ou Vie des Bretons de l'Armorique*, 3 vols., 1844. The Celtic language is still generally spoken, especially in lower Brittany, and a considerable body of traditional story and song is current among the people. Four dialects are pretty clearly marked. The whole duchy was formerly divided into nine bishoprics,—Rennes, Dol, Nantes, St Malo, and St Brieuc, in Upper Brittany; and Tréguier, Vannes, Quimper, and St Pol de Léon in Lower; and several of the larger towns were the seats of separate counts.

At the time of Cæsar's conquest of Gaul the north-western peninsula was inhabited by the Celtic tribes of the Veneti, the Curiosolitæ, and the Osismii; but our information in regard to them

is of the scantiest description. On the condition of this distinct, indeed, history is almost silent till the 5th century, when the invasion of Britain by the Saxons was followed by the migration across the channel of large numbers of the defeated islanders. The Breton chronicles contain an account of about a score of dukes from that period to the end of the 8th century; but how far the names and the narrative are merely mythical it would be hard to determine. The one great fact that is clearly evident is, that a violent contest for independence was maintained against the Frankish inroads. Under the early Carlovingians the country was for a time in rather more than nominal subjection; but it soon reasserted its independence. The 9th and 10th centuries are mainly remarkable for the wars that were continually breaking out between Brittany and the rising duchy of Normandy. Though Alan V. of Brittany had been intrusted with the guardianship of the youthful William of Normandy, and had fulfilled his trust to the full, yet under his successors Conan II., Hoel V., and Alan Fergent, the old enmity between the two countries broke out again and again. On the death in 1148 of Conan III., who had been defeated in a contest with his rebellious nobles, the succession was disputed by Hoel VI. and his brother-in-law, the count of Porhoet. The partizans of the former on their defeat submitted to Henry II. of England, who bestowed the



Map of Brittany.

duchy on his brother Geoffrey. Geoffrey's death two years after left the way open to the enterprise of Conan IV., grandson of Conan III., who had made his step-father prisoner, and was gradually obtaining possession of the whole duchy. The new duke, however, was forced not only to give his daughter Constance to Henry's son Geoffrey, but also in the long run to abdicate in his favour. On Geoffrey's death in 1186 the duchy became an object of dispute between the English and French kings, the latter being supported by the native nobility. To this rivalry the young duke Arthur fell a victim, murdered, as is usually supposed, by his uncle John of England. His sister Alice succeeded, under the protection of France, and was married to Pierre de Dreux, who thus became the first of a new line of dukes which lasted till the death of Francis II. in 1488. In 1491 the heiress Anne was forced to marry Charles VIII., and thus the duchy was held by the French crown. In 1532 it was formally united to France, but it retained a separate parliament till the Revolution.

Among the historians of Brittany may be mentioned Dom Lobineau, Dom Taillandier, Dom Morice, Daru, and De Courson. See also Trollope's *Summer in Brittany*, 1840; Mrs Bury Palliser, *Brittany and its Byeways*, 1869; Du Chatellier, *L'Agriculture et les classes agricoles de la Bretagne*, 1862.

BRITTON, the title of the earliest summary of the law of England in the French tongue, which purports to have been written by command of King Edward I. The origin and authorship of the work have been much disputed. It has been attributed to John le Breton, bishop of Hereford, on the authority of a passage found in some MSS. of the history of Matthew of Westminster; there are difficulties, however, involved in this theory, inasmuch as the bishop of Hereford died in 1275 (3 Edward I.), whereas allusions are made in Britton to several statutes passed after that time, and more particularly to the well-known statute "Quia emptores terrarum," which was passed in 18 Edward I. It was the opinion of Selden that the book derived its title from Henry de Bracton, the last of the chief justiciaries, whose name is sometimes spelled in the Fine Rolls Bratton and Bretton, and that it was a royal abridgment of Bracton's great work on the customs and laws of England, with the addition of certain subsequent statutes. The arrangement, however, of the two works is different, and but a small proportion of Bracton's work is incorporated in Britton. The work is entitled in an early MS. of the 14th century, which was once in the possession of Selden, and is now in the Cambridge University Library, "Summa de legibus Anglie que vocatur Bretone;" and it is described as "a book called Bretoun" in the will of Andrew Horn, the learned chamberlain of the city of London, who bequeathed it to the chamber of the Guildhall in 3 Edward III., together with another book called the *Mirroir des Justices*. Britton was first printed in London by Robert Redman, without a date, probably about the year 1530. Another edition of it was printed in 1640, corrected by Edmund Wingate. A third edition of it, with an English translation, has been lately published at the University Press, Oxford, 1865, by F. M. Nicholls, M.A. An English translation of the work without the Latin text had been previously published by R. Kelham in 1762.

BRITTON, JOHN, a topographical and antiquarian writer, was born at Kingston-St-Michael, near Chippenham, July 7, 1771. His birthplace, an old-world village of the dullest and sleepiest kind, had also the distinction of being the home of the antiquary John Aubrey. His parents were in humble circumstances, and he was left an orphan at an early age. He grew up with no better education than was to be had in the poor schools of his native Wiltshire village and neighbouring places, the last to which he was sent being at Chippenham. At the age of fourteen he became possessed of a small lot of books, and among them were *Robinson Crusoe*, the *Pilgrim's Progress*, and *The Life of Peter, Czar of Muscovy*. At sixteen he went to London,

and through the influence of a relative was apprenticed to a wine merchant. Prevented by failing health from serving his full six years, he found himself adrift in the world, without money, without friends, and without education. In his hand-to-hand fight with poverty he was put to strange shifts, becoming cellarman at a tavern and clerk to a lawyer, reciting and singing at a small theatre, and compiling a collection of common songs. During his apprenticeship he had read much in a loose, aimless manner; and gradually by successive small ventures he found his way into the broad paths of literature. A Salisbury publisher having projected a work on Wiltshire, invited Britton to undertake its preparation. The proposal was accepted; and in conjunction with his friend Edward Wedlake Brayley, Britton set himself to the task. Such was the small beginning of the voluminous work entitled *The Beauties of England and Wales*. The *Beauties of Wiltshire* appeared in two volumes in 1801, a third volume being added in 1825. The authors proceeded with other counties, and nine volumes of the entire series were their work. In the course of these early labours Britton's attention was especially drawn to antiquarian subjects; and thenceforth his proper field was before him, and in it he worked honourably. In 1805 appeared the first portion of his *Architectural Antiquities of Great Britain*, which extended to five volumes quarto, and was nine years in publication. On its completion Britton commenced his great work on the *Cathedral Antiquities of England*, the section on Salisbury Cathedral being the first published. It was completed in 1835, having been more than twenty years in progress, and forming altogether fourteen folio volumes. It is profusely illustrated by copperplate engravings.

As sole or joint author or editor Britton's name is attached to a large number of works of a like character. Among these may be mentioned the *Historical Account of Redcliffe Church, Bristol* (1813); *Illustrations of Fonthill Abbey* (1823); *Architectural Antiquities of Normandy*, with illustrations by Pugin, published in 1825–1827; *Picturesque Antiquities of English Cities* (1830); and the splendid *History of the Palace and Houses of Parliament at Westminster*, the joint work of Britton and Brayley, published in 1834–36. Mr Britton was a frequent contributor to the *Gentleman's Magazine* and other periodicals; he wrote the article "Shakespeare" for Rees's *Cyclopædia*, and the articles "Stonehenge," "Avebury," and "Tumulus" for the *Penny Cyclopædia*. In his later years he began to write his Autobiography, but did not carry the personal narrative far. The portion published is rich in literary anecdote of the times. Britton died in London, January 1, 1857, and his remains were interred in Norwood Cemetery. A *Descriptive Account of his Literary Works* was published by his assistant T. E. Jones. Britton was the originator of a new class of literary works. "Before his time," says Mr Digby Wyatt, "popular topography was unknown." He first combined antiquarian with topographical description. He effected a great improvement in the style and character of the illustrations of ancient monuments; and the general admiration excited by the engravings in his works gave rise to a novel interest in his subject, and became one of the incitements to deeper studies and investigations.

BRIVES-LA-GAILLARDE, a town of France, capital of an arrondissement in the department of Corrèze, situated in a beautiful and fertile plain twenty miles from Tulle. It is surrounded with elm-planted boulevards, and possesses a number of well-preserved houses of an early date. None of its public buildings (which comprise several churches, a theological seminary, and a college) are of much importance, except the church of St Martin, dating from the 13th century. The town carries on an active trade in cattle, wool, wine, oil, and grain, manufactures wax candles, copperwares, and cotton thread, and has millstone and slate quarries. Brives is of ancient origin, and for a long time disputed the title of capital of the Lower Limousin with the city of Tulle. It was the birthplace of the Cardinal Dubois. Population in 1872, 8417.

BRIXEN, a town of Austria in Tyrol, situated in the Pusterthal at the confluence of the Eisack and Rientz, in 40° 40′ N. lat. and 11° 37′ E. long., 104 miles from Vienna by rail. It is the seat of a bishop, and has a cathedral built in the 18th century, a theological seminary, a gymnasium, and several monasteries. There are iron and steel factories in the neighbourhood, and the baths of Maria-Louisa are supplied with water from a chalybeate spring. About nine miles from the town is the great fort of Franzensfeste, built in 1838, at the junction of the roads from Botzen, Innsbruck, and Pusterthal. Brixen (in Italian *Bressanone*) is mentioned at least as early as 901. In 1025 it became the seat of a bishop, and in 1038 was surrounded with walls. In 1174, 1234, and 1445 it was destroyed by fire; in 1519 it was stormed by the French under Gaston de Foix; and in 1525 it suffered from the rebellion of the peasants. Population in 1869, 4349.

BRIXHAM, a seaport town of England, in the county of Devon, about 200 miles from London, with a station about two miles distant on the South Devon Railway. The town is irregularly built on the cliffs to the south of Torbay, and its harbour is defended by a modern breakwater. It carries on a very extensive fishing and coasting trade, and is a place of resort for sea-bathing. In the early part of the present century it was the seat of a considerable military establishment, with fortified barracks at Bury Head, and it is celebrated in history as the spot where King William landed in 1688. Population of the parish in 1871, 6542.

BROACH, or BHARUCH, a district of British India under the jurisdiction of the governor of Bombay, extending from 21° 22′ to 22° 11′ N. lat. and from 72° 30′ to 73° 10′ E. long. It is bounded on the N. by the River Máhi, on the E. and S. by the territory of the Gaikwar, and on the W. by the Gulf of Cambay. Consisting chiefly of the alluvial plain at the mouth of the River Nerbudda, the land is rich and highly cultivated, and though it is without forests it is not wanting in trees. The district is well supplied with rivers, having in addition to the Nerbudda, the Mahi in the north and the Kíni in the south. The area is 1320 square miles; the population 350,322, of whom 248,343 are Hindus, 69,033 Mahometans, 3986 Buddhists, 3116 Pársís, and 24,703 belong to the aboriginal tribes. The population comprises several distinct races or castes, who, while speaking a common dialect, Gujaráthi, inhabit separate villages. Thus there are Koli Kembi or Voro (Borah) villages, and others whose lands are almost entirely held and cultivated by high castes, such as Rájputs, Bráhmans, or Pársís.

Except in the city of Broach, which has two steam ginning factories and a considerable general trade, agriculture is almost the sole industry of the district. The export of cotton, the principal agricultural product, amounted in 1872 to 88,471 bales. The most important cereal and pulse corps are—for the rains, jawári (*Holcus Sorghum*) rice, bágri (*Pencillaria spicata*), túr (*Cajanus indicus*), and múg (*Phaseolus Mungo*); and for the cold weather, wheat, til (*Sesamum indicum*), pea, gram (*Cicer arietinum*), wal (*Lablab vulgaris*), castor oil, and tobacco. The total revenue of the district amounted in 1872 to £318,972, of which £266,936 was imperial land revenue; £20,568 on account of the local land cess; stamps yielded £22,714; excise, £6823; and assessed taxes, £193. The imperial expenditure in the district amounted during the same time to £72,025. Of the whole area of the district, viz., 1320 square miles, 72 per cent. are returned as cultivated, 3 per cent. cultivable but not actually under tillage, and 25 per cent., including the sites of villages, river-beds, &c., as uncultivable. There are five towns with a population of over 5000 inhabitants,—Broach, 36,932; Jambusar, 14,924; Ankleswar, 9414; Amod, 6125; and Gajera, 5239. In the first two of these towns municipalities have been established. The district contains 191 schools, with an attendance of 6525 scholars. The total number of persons receiving or who have received some education amounts to 9·5 per cent. of the enitre population. The strength of the district police force is 415, giving to each man the charge of three square miles and 844 inhabitants. The principal criminal class is the Bhils, numbering about 24,000. The difficulty of arresting offenders of this race is increased by the fact that they are in league with members of their tribe in the native states of Baroda and Rájpipla, and can therefore with ease escape into foreign territory.

Broach, the principal place of the district of the same name, situated on an elevated mound, supposed to be artificial, on the northern bank of the Nerbudda, about 30 miles above its mouth, in 21° 42′ N. lat. and 73° 2′ E. long. The river is here a noble sheet of water, two miles wide at ebb tide, but shallow for the most part even at flood-tide, though there is then a deep but intricate channel admitting vessels of considerable burden. In 1872 the population of the town and municipality was returned at 36,932. As in the generality of eastern towns, the streets are narrow and the houses lofty. It has a considerable trade, and annually exports large quantities of raw cotton to Bombay. Broach is thought with some appearance of probability to have been the Barygaza of Ptolemy and Arrian. Upon the conquest of Guzerat by the Mahometans, and the formation of the state of that name, Broach formed part of the new kingdom. On its overthrow by Akbar in 1572, it was annexed to the Mughul empire and governed by a Nawáb. The Marhattás became its masters in 1685, from which period it was held in subordination to the Peshwá until 1772, when it was captured by a force under General Wedderburn (brother to Lord Loughborough), who was killed in the assault. In 1783 it was ceded by the British to Sindhiá in acknowledgment of certain services. It was stormed in 1803 by a detachment commanded by Colonel Woodington, and was finally ceded to the East India Company by Sindhiá under the treaty of Serji Anjangáon. Distance north from Bombay 190 miles.

BROADSTAIRS, a town of England, in the county of Kent, about a mile and a half to the south of the North Foreland, and three miles from Margate, on the London, Chatham, and Dover Railway. It has a small pier for fishing-boats—built in the reign of Henry VIII., a modern Gothic church, hotels, libraries, and bathing-establishments; and in the summer season it attracts a considerable number of visitors. There is an archway leading down to the shore, which bears that it was erected by George Culmer in 1540, and not far off is the site of a chapel of the Virgin, to which ships were accustomed to veil their top-sails as they passed. Population in 1871, 1926.

BROCCHI, Giovanni Battista, a celebrated Italian mineralogist and geologist, was born at Bassano, in February 1772. He studied at the university of Pisa, where his attention was especially turned to mineralogy and botany. In 1802 he was appointed professor of botany in the new Lyceum of Brescia; but he more particularly devoted himself to geological researches in the numerous excursions he made into the adjacent districts. The fruits of these labours appeared in different publications, particularly in his *Treatise on the Iron Mines in the department of Mella;* and his *Essay on the Physical Constitution of the Metalliferous Mountains of the Valley of Trompia,* which appeared in 1807. His valuable researches procured him, in the following year, the office of inspector of mines in the recently established kingdom of Italy, which enabled him to extend his investigations over a great part of Central and Southern Italy, as well as its northern districts. In 1811 he produced a valuable memoir *On the Mineralogy of the Valley of Fassa and the Tyrol,* but his most important work is the great *Geologie Fossile Subapennina con Osservazioni Geologiche sulle Apennini, e sul Suolo Adjacente,* 2 vols. 4to, Milan, 1814, containing most accurate details of the structure of the Apennine range, and an account of the fossils of their strata. These subjects were further illustrated by his valuable geognostic map and his *Catalogo ragionato di una Raccolta di Rocche, disposto con ordine Geografico, per servire d'Illustrazione della Carta Geognostica dell' Italia,* Milan, 1817. His work, *Dello Stato Fisico del Suolo di Roma,* with its accompanying map, is admirable for accuracy and judgment. In it he has corrected the erroneous views of Breislak, who conceived that the Eternal City occupies the site of a volcano, to which he ascribed the tufa and other volcanic materials that cover the seven hills. Brocchi, on the other hand, has satisfactorily shown that they are derived either from Mont Albano, an extinct volcano, 12 miles from Rome, or from Mont Cimini, still further to the north of the city. Indeed he has shown that the streams or beds of tufa may be traced almost uninterruptedly from that mountain to Rome. Several minor papers by him, on other mineralogical subjects, appeared in the *Biblioteca Italiana* from 1816 to 1823. In the latter year Brocchi sailed for Egypt, and engaged with his usual ardour in exploring the geology of that country and its mineral resources, every facility being granted by Mehemet Ali, who in 1825 appointed Brocchi one of a commission to examine and organize his conquest of Sennaar, but the naturalist, unfortunately for science, fell a victim to the climate, at Khartum, in September 1826.

BROCKHAUS, Friedrich Arnold, an eminent German publisher, was born in Dortmund, on the 4th May 1772. He was educated at the gymnasium of his native place, and from 1788 to 1793 served an apprenticeship in a mercantile house at Düsseldorf. He then devoted two years at Leipsic to the study of modern languages and literature, after which he set up at Dortmund an emporium for English goods. In 1810 he transferred this business to Arnheim, and in the following year to Amsterdam. In 1805, having given up his first line of trade, he, in conjunction with a friend, began business as a publisher. Two journals projected by him were not suffered by the Government to survive for any length of time, and in 1810 the complications in the affairs of Holland induced him to return homewards. In 1811 he settled at Altenburg. About three years previously he had purchased the copyright of the *Conversations-Lexicon,* which had been begun in 1796, and in 1810–11 he completed the first edition of this celebrated work. A second edition under his own editorship was begun in 1812, and was received with universal favour. His business expanded rapidly, and in 1817 he removed to Leipsic, where he established a large printing-house. Among the more extensive of his many literary undertakings were the critical periodicals—*Hermes,* the *Literarische Conversationsblatt* (afterwards the *Blätter für literarische Unterhaltung*), and the *Zeitgenossen,* and some large historical and bibliographical works, such as Von Raumer's *Geschichte der Hohenstaufen,* and Ebert's *Allgem. Bibliographis. Lexicon.* The work distinctively associated with his name, and with the publishing house which has been carried on by his sons, is the *Conversations-Lexicon,* in many ways the completest and best encyclopædia of its kind, which has now reached its twelfth edition. Brockhaus died in 1823.

BROCKLESBY, Richard, a physician of considerable reputation, was born in Somersetshire, 11th August 1722. He was educated at Ballytore, in Ireland, studied medicine at Edinburgh, and finally graduated at Leyden in 1745. In 1751 he was admitted a licentiate of the Royal College of Physicians at London, of which he afterwards became a fellow. In 1758 he was appointed physician to the army, in which capacity he served in Germany during the greater part of the Seven Years' War, and in the course of it was chosen physician to the hospitals for British forces. The results of his observations during this period were published in 1764, under the title of *Economical and Medical Observations from 1758 to 1763, tending to the Improvement of Medical Hospitals.* He had already given many proofs of his industry and his attainments by papers published in the *Transactions of the Royal Society.* His *Dissertation on the*

Music of the Ancients appeared in 1749, and his *Oratio Harveiana* in 1760. Shortly after this he was appointed by the duke of Richmond physician-general to the royal regiment of artillery and corps of engineers, an appointment that gave him constant access to the laboratory of Woolwich, and it was by his advice that a professorship of chemistry was added to the establishment of the college. In his latter years he withdrew altogether into private life. The circle of his friends included some of the most distinguished literary men of the age. His intimacy with Burke had commenced at school, and soon ripened into the warmest friendship. He was also warmly attached to Dr Johnson, to whom he offered an annuity of £100 during the remainder of his life to enable him to visit the Continent for the recovery of his health; and when this offer was declined, he pressed him to reside in his house, as more suited to his health than that in which he then lived. He attended the great moralist on his deathbed. The same generous disposition was manifested in his conduct to Burke, to whom he presented £1000, a sum he had intended to leave him by will. Dr Brocklesby died suddenly 11th December 1797. He left his entire fortune, with the exception of a few legacies, to his two nephews, Dr Thomas Young and Mr Beeby.

BRODERIP, William John, a distinguished writer on natural history, was born in Bristol, probably in 1787. He was educated at the school conducted by the Rev. Samuel Seyer, and proceeded to Oriel College, Oxford, where he began the study of law. He was called to the bar in 1817, and took part for several years in editing the law reports. In 1822 he was appointed by Sir Robert Peel one of the metropolitan police magistrates, a post which he occupied for thirty-four years. All his leisure time was devoted to the favourite study of his earlier days—natural history. He was a member of most of the scientific societies, contributed numerous papers to their Transactions, and did much to further the study of zoology in England. He acted for many years as vice-president of the Zoological Society. The zoological articles in the *Penny Cyclopædia* were written by him, and made him widely known as an original investigator and able expositor. A series of articles contributed to *Fraser's Magazine* were reprinted in 1848 as *Zoological Recreations*, and were followed in 1852 by *Leaves from the Note-Book of a Naturalist*. Broderip died on the 27th February 1859.

BRODIE, Sir Benjamin Collins, Bart., a distinguished physiologist and surgeon, was born in 1783 at Winterslow, county of Wilts, and died at Broome Park, 21st October 1862, in the 79th year of his age. His paternal grandfather, connected with the family of Brodie of Brodie, was born in Banffshire about the year 1710, and came as an adventurer to London, where he acquired considerable wealth as an army clothier. One of his sons, the father of the subject of this notice, was educated at the Charter House, and afterwards at Worcester College, Oxford, where he took holy orders. Here he probably acquired the friendship of the first Lord Holland, with whom he afterwards lived at Holland House. The second Lord Holland having purchased the estate of Winterslow, Mr Brodie rented a cottage near the same place. The second Lord Holland died in 1774, and directed in his will that Mr Brodie should have offered to him the presentation of the first of three livings which he had in his gift when a vacancy occurred. This event took place in consequence of the death of the incumbent of Winterslow, and Mr Brodie became rector of the parish. In 1775 he married one of the daughters of Mr Collins of Milford, a banker of Salisbury. They had six children,—four sons and two daughters,—and the subject of this sketch was their fourth child.

He received his early education from his father, who appears to have been a man of energy, ability, and method; and at an early age he had acquired a considerable knowledge of the classics. When the time for choosing a profession arrived, his father intimated to him that he was intended for that of medicine, and accordingly, in the autumn of 1801, he began to attend the anatomical lectures of the celebrated Abernethy in London. As his family was connected by marriage with several of the leading members of the profession, such as Dr Denman (the father of the first Lord Denman), Dr Baillie, and Sir Richard Croft, the young student enjoyed many advantages of distinguished professional society, but it does not appear that at this period of his life he had any predilection for medical studies or any aptitude for surgical work. The great eminence as an operator to which he afterwards attained was gained, as he himself said, by persistent application and perseverance.

He devoted great attention to the clinical study of disease, and began to make an elaborate series of notes of cases which came under his observation. This habit he continued throughout life, and thus gradually amassed that enormous amount of practical experience which afterwards gave his advice as a consulting surgeon such weight.

Like most young adventurers in the fields of science of that day, he early began to teach. He gave many courses of lectures upon anatomy, not only as it bore on surgical practice, but as a science having important physiological and teleological relations. In 1808 he became assistant-surgeon to St George's Hospital, and he continued on the staff of that institution for over thirty years. This gave him the opportunity of teaching clinically, and he soon acquired a reputation as an able and fluent extempore speaker. In 1810 he was elected a fellow of the Royal Society, and in the following year communicated a series of papers "On the Influence of the Brain on the Action of the Heart, and on the Generation of Animal Heat." In 1812 he also communicated a paper "On the Mode in which Death is produced by certain Poisons." These papers were founded upon a series of careful physiological experiments, having for their object to determine, first, the relation of the nervous system to the circulatory and nutritive systems in higher animals, and, second, to ascertain, if possible, how poisons produce death. The most important fact ascertained by the first series of experiments was that the stoppage of the heart's action at the moment of death does not depend on the removal of the influence of the brain, but on the arrest of respiration. He also pointed out some important facts which could only be accounted for by supposing that the nervous system has an influence on the production and diffusion of animal heat, an idea not then generally accepted. For these researches he received the Copley medal of the Royal Society in 1811. In 1813 he delivered the Croonian lecture, "On the Effect of the Nerves on the Heart and on the Involuntary Muscles," and in 1814 he contributed another paper "On the Influence of the Nerves of the Eighth Pair on the Secretions of the Stomach." In 1816 he performed many experiments on animals, to ascertain the influence of bile on the food during its passage through the bowels. These papers comprehend what Brodie accomplished in physiology. They are all characterized by lucidity, conciseness, sound judgment, and a modest interpretation of results. They are valuable at the present time not so much for the facts they contain, most of which are now incorporated in the general mass of scientific knowledge, but as admirable illustrations of the application of the experimental method of research to physiological questions.

At this period of his career Brodie rapidly glided into a large and lucrative practice, and more especially he quickly gave evidence of superior powers as an operator, having

knowledge, coolness, and readiness of resource. From time to time he wrote upon surgical questions, contributing numerous papers to the *Transactions of the Royal Medical and Chirurgical Society*, and to the medical journals. Probably his most important work is that entitled *Pathological and Surgical Observations on the Diseases of the Joints*, in which he attempts to trace the commencements of disease in the different tissues which form a joint, and to give an exact value to the symptom of pain as evidence of organic disease. The thoughts suggested by this volume led to the adoption by surgeons of measures of a conservative nature in the treatment of diseases of the joints, by which the number of amputations has been reduced, and many limbs and lives have been saved. He also wrote on diseases of the urinary organs, and on local nervous affections of a surgical character. Brodie was a man of restless activity; to use his own words, he felt "his happiness to be in a life of *exertion*." When released from professional cares he had recourse to literary and scientific pursuits, and especially to the study of psychological questions. He was fond of reading, collecting facts, and speculating on all matters connected with mental phenomena; and in 1854 he published anonymously a work entitled *Psychological Inquiries—the First Part*. A second edition of this work appeared in 1855, a third in 1856, a fourth in 1862, and in the same year the *Second Part* was also published. This work enjoyed well-merited popularity, as it was written in clear untechnical language, and revealed the speculations of the writer concerning the mind of man. When the name of the author became known, the greatest interest was excited in the work, although it contains nothing new to professed psychologists. He wrote also occasionally for the quarterly reviews.

Brodie received many honours during his career. He was the medical adviser of three successive sovereigns, and in 1834 he was elevated to the rank of a baronet. It is generally believed that he might have been created a peer had he desired the honour. He became a corresponding member of the French Institute in 1844, D.C.L. of Oxford in 1855, and president of the Royal Society in 1858; and he was the first president of the Medical Council under the Act for the Education and Registration of the Medical Profession.

A complete edition of his works, with an autobiography, in three volumes, appeared in 1865, collected and arranged by Charles Hawkins, fellow of the Royal College of Surgeons of England; and a generous and discriminative biographical sketch, by Professor Henry W. Acland of Oxford, appeared in the obituary notices in the *Proceedings of the Royal Society* for 1863. (J. G. M.)

BRODY, a town of Austria, in the circle of Zloczow, in Galicia, near the Russian frontier. It contains three large synagogues, a Jewish hospital, and a Jewish college, and from its prevailing Jewish character has been called the German Jerusalem. There are also one Roman Catholic and three Greek churches and an industrial school. Its castle is the residence of the Counts Potocki. It is the seat of an extensive trade carried on with Russia and Turkey, and has two large annual fairs, the principal articles of sale being wool, cotton, silk, and peltry. In 1869 the population, of which about two-thirds are Jews, amounted to 18,890. Brody was founded in 1679 under the name of Lubicz, and was raised to the rank of a free commercial city in 1779.

BROGLIE, Achille Léonce Victor Charles, Duc de, peer of France, was born in Paris 28th November 1785, and died 25th January 1870. The family from which this eminent statesman descended was of Piedmontese origin, but it won its honour in the service of France. The first Marshal de Broglie (1639–1727) served with distinction under Louis XIV.; his son, known as the Chevalier de Broglie (1671–1745), was raised to the highest grade in the French peerage for his gallant military service at Guastalla and at Prague in 1742, but he refused the rank of marshal of France, which was offered to him by the regent, on the ground that his father, who was still alive, deserved it more than he did. The next in descent was the second marshal (1718–1804), who commanded the French armies in the Seven Years' War, for which he was created a prince of the empire, and though subsequently disgraced and exiled by the intrigues of the Condés, he was recalled in 1789 by Louis XVI. to the office of commander-in-chief. To stem the tide of the Revolution was impossible. The marshal speedily fell from power, emigrated to Germany, refused the solicitation of Napoleon to return to France, and died at Münster in 1804.

The son of this veteran followed an opposite course and met with a more untimely end. He adopted the liberal opinions of the time. He followed Lafayette and Rochambeau to America. He sat in the Constituent Assembly, constantly voting on the Liberal side. He served as chief of the staff to the Republican army on the Rhine; but, like many other champions of the Revolution, he was denounced, arrested, dragged to Paris, and executed on the 27th June 1794. The parting injunction he left to his son, Victor de Broglie, the subject of this notice, then a boy nine years old, was ever to remain faithful to the cause of liberty, even though it were ungrateful and unjust. His father murdered, his mother imprisoned, his property confiscated and plundered, the young de Broglie first appears in life in wooden shoes and a red cap of liberty, begging an assignat from the younger Robespierre. Yet he adhered to the cause for which his father had died; he maintained through life the principles of 1789. He seemed to have forgotten his own rank, until he was reminded of it at the Restoration by a writ of summons to the Chamber of Peers, and in early life he served, not unwillingly, as one of the officers of the council of state of the emperor Napoleon I.

In 1815, before he had completed his 30th year, the Duc de Broglie was summoned by Louis XVIII. to the Chamber of Peers. He combined, in a manner rare in France, the qualities we are wont to respect in the most eminent members of the British aristocracy,—high rank, independent fortune, unblemished integrity, unflinching patriotism, and a sincere and consistent attachment to liberal opinions. The first incident in his parliamentary life was the trial of Marshal Ney, and on this occasion he had the courage to speak and vote alone for the acquittal of the prisoner, on the ground that he was not guilty of deliberate treason; no other peer of France supported his protest on that occasion. During the Restoration he continued to take an active part in the defence of liberal opinions and measures. He refused to take office in the cabinet of M. de Serre. He opposed the reactionary policy of the court. He supported the short-lived administration of M. de Martignac, and he acted with the party known as the *doctrinaires*, of which M. Royer-Collard was the founder, and M. Guizot the ablest representative. Meanwhile, in 1816, he had married the daughter of Madame de Stael, a union of unbroken domestic happiness; and he had pledged himself to that sacred cause of Negro emancipation, in which he was the worthy rival and ally of Clarkson, Buxton, Wilberforce, and Brougham. The revolution of July 1830 imposed fresh duties on the Duc de Broglie. Though reluctant to take office from his cold, retiring, and unambitious temperament, he consented to hold the ministry of public worship in the first cabinet of Louis Philippe's reign, and in 1832, after the death of Casimir Périer, he was prevailed upon to take the more important department of foreign affairs. In this function he

strengthened the alliance of France with England; he negotiated the Quadruple alliance; he contributed to the settlement of the Belgian and Greek questions; and he laboured with success to preserve the peace of Europe. He was out of office from March 1834 to March 1835, but he returned to power at the latter date, and this time as the head of the cabinet. He was riding by the side of the king when Fieschi's "infernal machine" was fired on the royal cortege, and a bullet passed through the collar of his coat. In 1836 the Government was beaten on the question of the reduction of the five per cents., and M. de Broglie retired permanently from official life. The king, it must be said, had never found in him a congenial minister. His manner was dry and somewhat harsh, his character unbending, and for the remainder of the reign of Louis Philippe, M. de Broglie, though not in opposition, was the censor rather than the servant of the crown. With M. Guizot, though not in office, he preserved through life the relations of the closest personal friendship and political union. The overthrow of the constitutional monarchy in 1848 was a heavy blow to this parliamentary veteran, for he felt that the form and system of government to which he was most attached were at an end for ever. He consented, however, from patriotic motives to sit in the republican assemblies of 1848, and as a member of the section known as the "Burgraves" he laboured to counteract some of the evils of universal suffrage, and to avert the catastrophe which he saw to be impending over France. He shared with his colleagues the indignity of the *coup d'état* of December 2, 1851, and remained for the remainder of his life one of the bitterest enemies of the imperial régime, although he has been heard to remark with that caustic wit for which he was famous, that the empire was "the government which the poorer classes in France desired and the rich deserved." The last twenty years of his life were devoted chiefly to philosophical and literary pursuits. Having been brought up by his step-father, M. d'Argenson, in the sceptical opinions of the time, he gradually arrived, by study and reflection, at a full and sincere belief in the truth of the Christian religion. "I shall die," said he, a "penitent Christian and an impenitent Liberal." His literary works, though few of them have been published, were rewarded by a seat in the French Academy, and he was also a member of another branch of the French Institute, the Academy of Moral and Political Science. In the labours of those learned bodies he took an active and assiduous part; and on his death, which took place at the advanced age of 85, just before the lamentable events of 1870, he was followed to the grave by representatives of all that is most illustrious in the political and literary society of France, revered as one of the wisest and most upright men of his age. He was succeeded in the honours of his house by Albert de Broglie, his eldest son, also distinguished by his literary works, and who has since 1871 played no inconsiderable part in the political affairs of his country as a leading member of the National Assembly, and for sometime head of the cabinet of Marshal Macmahon. (H. R.)

BROKER, a word derived variously from the French *broier*, to grind, and *brocarder*, to cavil or higgle. and the Saxon *broc*, misfortune.

A broker is an agent or intermediate person appointed for transacting special business on account of another, but differing somewhat from an ordinary factor in functions and responsibility. Of this class there are various descriptions, exercising employment without the smallest analogy, though all are brought under the general name of brokers: of these the principal are—exchange brokers, whose province is to ascertain the rates and relation of exchange between countries; stock-brokers, who negotiate transactions in the public funds; insurance brokers, who effect insurances on lives or property; and pawnbrokers, who advance money on goods, on the condition of being allowed to sell the goods if the sum advanced is not repaid with interest within a limited time. See AGENT and INSURANCE.

Separating pawnbrokers, and those dealers in old wares who are called brokers, as both distinct from the class to whom the term in its broader acceptation applies, the broker is an agent for both parties, the buyer and the seller; and for the general principles of jurisprudence applicable to his position, reference may be made to the article AGENT. It is a marked peculiarity, however, of the broker as an agent, that his quality of agency is not only palpable in the face of the transactions, but he is agent for both parties. The function of the broker is indeed a very simple one, and easily separates itself from the usual intricacies of the law of sale and of agency. It is his proper function to find buyers and sellers, and to bring them together that they may transact with each other. Hence the rise of such a class in any department of business is an indication of its great increase. In small towns, and in narrow and peculiar departments of business, the buyers and the sellers know each other, and need not be at the expense of employing a third party. But where both bodies are numerous, and the individual members of each find enough to occupy their attention in the production of their commodity, or its purchase and distribution, there is economy in the establishment of a distinct class who bring the buyer and the seller together. The broker usually gives what are called bought and sold notes to his clients, and some nice questions have arisen as to the effect of these when they do not correspond with each other or with the entry in the broker's books. The amount of broker's commission is in some few cases fixed by statute,—*e.g.*, under 10 Anne c. 19, § 120, a fine of £20 is imposed on brokers charging more than 2s. 9d. per cent. for buying or selling tallies, exchequer tickets, bank bills, &c. Generally it is settled by agreement with the principals or by the custom of trade. The brokers for the purchase and sale of goods within the city of London are a body with peculiar privileges, and acting under special licensing regulations, some of which date back to the reign of Henry VIII. The London Brokers' Relief Act (1870) has considerably altered their position, but they must still be admitted by the court of mayor and aldermen, and the penalty of £100 for acting as a broker without qualification may still be imposed. A list of London brokers is kept by the mayor and aldermen; and if a broker has been convicted of felony or fraud, or certified by a superior judge to have been guilty of fraud, he may be absolutely or for a time disqualified. There has been some doubt as to the class of persons falling under these regulations; ship-brokers and auctioneers, it would appear, do not.

BROMBERG, a town of Prussia, capital of a government in the province of Posen, is situated 70 miles north of the city of that name on the River Brahe, which is there crossed by a fine new railway bridge. Its public buildings comprise two Roman Catholic churches, a Protestant church, and a Jewish synagogue, a gymnasium, a seminary, a workhouse and penitentiary, a hospital, and a military storehouse. It has large mills, manufactures linen and woollen stuffs, leather, tobacco, Prussian blue, sugar, chicory, vinegar, beer, brandy, and oil, and carries on an active transit trade. The Bromberg Canal, constructed in 1773–4 by command of Frederick II., at a cost of 700,000 dollars, connects the Brahe with the Netz, and thus establishes communication between the Vistula, the Oder, and the Elbe. Bromberg is mentioned as early as 1252. From 1327 to 1343 it was in the hands of the Teutonic Order.

Destroyed in war it was restored by Casimir of Poland in 1346, and down to the close of the 16th century it continued to be a flourishing commercial city. It afterwards suffered so much from war and pestilence that about 1772, when the Prussians took possession, it contained only from five to six hundred inhabitants. By the treaty of Tilsit it was transferred to the duchy of Warsaw; in 1813 it was occupied by the Russians, and in 1815 it was restored to Prussia. Population in 1871, 27,740.

BROME, ALEXANDER, a minor English poet, was born in 1620, and died in 1666. He was an attorney in the lord mayor's court, and was the author of many of the songs and epigrams that were published in favour of the Royalists and against the Rump. These, together with his epistles and epigrams, translated from different authors, were all printed in one volume, octavo, after the Restoration. He published a translation of Horace by himself and others, and was the author of a comedy entitled *The Cunning Lovers*. He also edited two volumes of Richard Brome's plays.

BROME, RICHARD, a dramatic writer in the reign of Charles I., and a contemporary of Dekker, Ford, Shirley, and others. He was originally a servant of Ben Jonson; but he soon acquired a high literary reputation, and was addressed in some lines by his quondam master on account of his comedy entitled *The Northern Lass*. Brome's genius lay entirely in comedy. His plots are original and well managed, and his characters, which for the most part are strongly marked, were drawn from his own experience. He has left fifteen comedies. See Ward's *English Dramatic Literature*, 1875, vol. ii., for a good notice of Brome.

BROMINE, one of the halogen group of non-metallic chemical elements, which comprises three other members,—chlorine, iodine, and fluorine. The whole group has many properties in common, the most marked being their behaviour towards hydrogen, uniting with it atom for atom, forming gaseous condensible acid compounds, which are all produced by similar reactions, and which yield in combination with metals crystals of uniform structure. Bromine was discovered in 1826 by Balard, who extracted it from the water of the Mediterranean during his researches in connection with the sea-water. At ordinary temperatures it is a deep brownish-red liquid, emitting a strong disagreeable odour (whence its name, from βρῶμος, a stink), having a specific gravity of 2·96, freezing into a red-brown crystalline mass at $-24·5°$ C., and boiling at 63° C. Its combining equivalent or atomic weight is 80. Bromine is an element of great chemical activity, and of the highest interest in scientific chemistry on account of its combinations, and especially on account of the products of its substitution for hydrogen in organic compounds.

Although very widely disseminated, since it is found in ocean water, bromine is nowhere an abundant element. It is a constituent of some silver ores from Mexico and South America; it is very generally found in strong saline springs, as well as associated with deposits of salt; and it is present in many marine plants. The waters of the Atlantic, according to Von Bibra, contain 24 grains per gallon; while Herepath's analysis gives Dead Sea water a strength of 121·5 grains per gallon. It is only from the waters of certain saline springs in America that bromine is prepared as a direct product. At several places in western Pennsylvania and West Virginia the manufacture is carried on extensively, 125,000 lb having been extracted in 1870. In Europe bromine is only obtained as a secondary product of the preparation of potash and other alkaline salts, its chief source being the mother-liquors of the kelp manufacture, brine springs, and especially the Stassfurth saline deposits, near Magdeburg, Prussia. The produce at Stassfurth in 1873 amounted to about 10,000 lb; and it is estimated that the yield of English and French works was, taken together, about the same.

On the commercial scale bromine is prepared at Stassfurth from the liquids which have been exhausted of all their crystallizable soda and potash salts, and from which also a deposit of chloride of magnesium has been obtained. This final mother-liquor is found to contain from 0·3 to 0·5 per cent. of bromine, in the form of bromide of potassium. To separate the bromine the liquor is introduced into a sandstone apparatus similar to that used for the evolution of chlorine from common salt,—the process and reaction being similar in both cases. In this it is mixed with black oxide of manganese and sulphuric acid in definite proportions, and heated by a current of steam. The red vapour of bromine is given off and led by a pipe into a condensing worm of earthenware, and received into a series of three Woulfe's bottles, the first of which contains water, and the others alkaline ley and iron filings. The reaction which takes place is thus represented—

$$2KBr + MnO_2 + 3H_2SO_4$$
$$= 2KHSO_4 + MnSO_4 + 2H_2O + 2Br,$$

—sulphates of potash and manganese, water, and free bromine being produced from bromide of potassium, manganese dioxide, and sulphuric acid. Pure bromine vapour distils over at first, but as the distillation proceeds chlorine is gradually evolved, and from this the bromine may be freed by shaking up with a solution of bromide of potassium, which yields up its bromine to combine with chlorine. On account of its peculiarly irritating action on the organs of respiration, very great precautions have to be taken to protect workmen from the fumes of bromine, and it is indispensable that those engaged in the industry should abstain from all alcoholic liquors.

The chief industrial application of bromine and its compounds is in medicine, for which it is used in the form of bromide of potassium, bromide of ammonium, and bromide of sodium, besides in various combinations with alkaloids and organic substances. It is, however, most largely employed as bromide of potassium, a salt prepared on the large scale by the decomposition of potassium carbonate by the bromide of iron. It is also prepared by passing the vapour of bromine into a solution of caustic potash, when a mixture of bromide and bromate of potassium is produced. The mixed salts are reduced to a uniform bromide by burning with coal dust. Bromide of silver is employed to some extent in photography, and, according to the experiments of Vogel, it possesses a peculiar sensitiveness for the red, green, and yellow colours, which are not acted on by other photographic agents. During the American Civil War (1861–5) bromine came into use as a disinfectant in military hospitals, a purpose to which it was also applied in the Franco-German War in 1870–1. For such purposes it was found to possess several advantages over chlorine, which, however, has the recommendation of cheapness and abundance. It has long been hoped that bromine might be substituted for iodine in the preparation of the several coal-tar colours, but hitherto the attempts in that direction have not been successful. Eosine, a tetrabromated potassium salt, is the only dye into which bromine at present enters. The use of bromine has been suggested by Dr Rudolf Wagner in several metallurgical operations, in which he anticipates it might be of great service. He proposes, in place of the present wasteful method of reducing mercury from cinnabar, to digest the ore in an aqueous solution of bromine, whereby a bromide of mercury would be formed. He also suggests that bromine might be advantageously applied to the extraction of gold from poor auriferous ore, in a manner analogous to Plattner's chlorination process. Further, it is recom-

mended for the refining of gold by the formation of a bromide; and it is thought that bromine vapour might be used with advantage for toughening brittle gold.

BROMLEY, a market-town of England, in the county of Kent, 10 miles S.E. of London. It is situated on high ground to the north of the river Ravensbourne, and since the opening of the railway has become a favourite residence for men of business from London. It has a town-hall—built in 1864, an old market-house, a literary institution, and a college, originally founded in 1666 by Bishop Warner for the residence and support of clergymen's widows. The church is a fine Gothic building, containing some handsome monuments; and in the vicinity is a palace, erected in 1777 in room of an older structure, for the bishops of Rochester, to whom the manor has belonged since the time of Ethelbert. In the gardens attached is a mineral spring known as St Blaze's Well, which was in great repute before the Reformation. The population of the parish, which in 1861 was only 5505, amounted at the census of 1871 to 10,674. The parish includes the villages of Plaistow, Sundridge, Bickley, Widmore, Elmstead, Southboro', and Bromley Common.

BROMSGROVE, a market-town of England, in the county of Worcester, 13 miles S. by W. of Birmingham, with a station on the Birmingham and Worcester Railway, at the distance of a mile and a half. The church of St John is a fine old building, restored in 1858, with a tower and spire 189 feet in height. The free grammar school, founded by Edward VI., has been recently enlarged; and a literary institute and a school of art have been established. The principal manufactures of the town are nails, buttons, needles, and coarse linen stuffs; and there are also waggon-works and malt-kilns. The population of the Improvement District in 1871 was 6967.

BRONCHITIS, inflammation of the mucous membrane of the bronchial tubes. Well known as one of the most common diseases of the climate of Great Britain, bronchitis exists in either an *acute* or a *chronic* form.

Acute bronchitis, like other inflammatory affections of the chest, generally arises as the result of exposure to cold, particularly if accompanied with damp, or of sudden change from a heated to a cool atmosphere. The symptoms vary according to the severity of the attack, and more especially according to the extent to which the inflammatory action spreads in the bronchial tubes. The disease usually manifests itself at first in the form of a catarrh, or common cold; but the accompanying feverishness and general constitutional disturbance proclaim the attack to be something more severe, and symptoms denoting the onset of bronchitis soon present themselves. A short, painful, dry cough, accompanied with rapid and wheezing respiration, a feeling of rawness and pain in the throat and behind the breast bone, and of oppression or tightness throughout the chest, mark the early stages of the disease. In some cases, from the first, symptoms of the form of asthma known as the *bronchitic* are superadded, and greatly aggravate the patient's suffering. See ASTHMA.

After a few days expectoration begins to come with the cough, at first scanty and viscid or frothy, but soon becoming copious and of purulent character. In general, after free expectoration has been established the more urgent and painful symptoms abate; and while the cough may persist for a length of time, often extending to three or four weeks, in the majority of instances convalescence advances, and the patient is ultimately restored to health, although there is not unfrequently left a tendency to a recurrence of the disease on exposure to its exciting causes.

When the ear or the stethoscope is applied to the chest of a person suffering from such an attack as that now described, there are heard in the earlier stages snoring or cooing sounds, mixed up with others of wheezing or fine whistling quality, accompanying respiration. These are denominated dry sounds, and they are occasionally so abundant and distinct as to convey their vibrations to the hand applied to the chest, as well as to be audible to a bystander at some distance. As the disease progresses these sounds become to a large extent replaced by others of crackling or bubbling character, which are termed moist sounds or râles. Both these kinds of abnormal sounds are readily explained by a reference to the pathological condition of the parts. One of the first effects of inflammation upon the bronchial mucous membrane is to cause some degree of swelling, which, together with the presence of a tough secretion closely adhering to it, tends to diminish the calibre of the tubes. The respired air as it passes over this surface gives rise to the dry or sonorous breath sounds, the coarser being generated in the large, and the finer or wheezing sounds in the small divisions of the bronchi. Before long, however, the discharge from the bronchial mucous membrane becomes more abundant and less glutinous, and accumulates in the tubes till dislodged by coughing. The respired air, as it passes through this fluid, causes the moist râles above described. In most instances both moist and dry sounds are heard abundantly in the same case, since different portions of the bronchial tubes are affected at different times in the course of the disease.

Such are briefly the main characteristics presented by an ordinary attack of acute bronchitis running a favourable course.

The case is, however, very different when the inflammation spreads into, or when it primarily affects the minute ramifications of the bronchial tubes which are in immediate relation to the air-cells of the lungs, giving rise to that form of the disease known as *capillary bronchitis*. When this takes place all the symptoms already detailed become greatly intensified, and the patient's life is placed in imminent peril in consequence of the interruption to the entrance of air into the lungs, and thus to the due aeration of the blood. The feverishness and restlessness increase, the cough becomes incessant, the respiration extremely rapid and laboured, the nostrils dilating with each effort, and evidence of impending suffocation appears. The surface of the body is pale or dusky, the lips are livid, while breathing becomes increasingly difficult, and is attended with suffocative paroxysms which render the recumbent posture impossible. Unless speedy relief is obtained by successful efforts to clear the chest by coughing and expectoration, the patient's strength gives way, somnolence and delirium set in, and death ensues. All this may be brought about in the space of a few days, and such cases, particularly among the very young, sometimes prove fatal within forty-eight hours.

During life, in addition to the auscultatory signs present in ordinary bronchitis, there generally exist in this form of the disease abundant fine moist râles at the bases of both lungs; and the appearance of these organs after death shows the minute bronchi and many of the air-cells to be filled with matter similar to that which had been expectorated, and which has thus acted as a mechanical hindrance to the entrance of the respired air and caused death by asphyxia.

Acute bronchitis must at all times be looked upon as a severe and even serious ailment, but there are certain circumstances under which its occurrence is a matter of special anxiety to the physician. It is pre-eminently dangerous at the extremes of life, and mortality statistics show it to be one of the most fatal of the diseases of those periods. This is to be explained not only by the well recognized fact that all acute diseases tell with great severity on the feeble frames alike of infants and aged people, but more

particularly by the tendency which bronchitis undoubtedly has in attacking them to assume the capillary form, and when it does so to prove quickly fatal. The importance, therefore, of early attention to the slightest evidence of bronchitis among the very young or the aged can scarcely be overrated.

Bronchitis is also apt to be very severe when it occurs in persons who are addicted to intemperance. Again, in those who suffer from any disease affecting directly or indirectly the respiratory functions, such as consumption or heart disease, the supervention of an attack of acute bronchitis is an alarming complication, increasing, as it necessarily does, the embarrassment of breathing. The same remark is applicable to those numerous instances of its occurrence in children who are or have been suffering from such diseases as have always associated with them a certain degree of bronchial irritation, such as measles and hooping-cough.

One other source of danger of a special character in bronchitis remains to be mentioned, viz., collapse of the lung. Occasionally a branch of a bronchial tube becomes plugged up with secretion, so that the area of the lung to which this branch conducts ceases to be inflated on inspiration. The small quantity of air imprisoned in the portion of lung gradually escapes, but no fresh air enters, and the part collapses and becomes of solid consistence. Increased difficulty of breathing is the result, and where a large portion of lung is affected by the plugging up of a large bronchus, a fatal result may rapidly follow, the danger being specially great in the case of children. Fortunately, the obstruction may sometimes be removed by vigorous coughing, and relief is then obtained.

With respect to the treatment of acute bronchitis, in those mild cases which are more of the nature of a simple catarrh, little else will be found necessary than confinement in a warm room, or in bed, for a few days, and the use of light diet, together with warm diluent drinks. Additional measures are, however, called for when the disease is more markedly developed. Medicines to allay fever and promote perspiration, such as the well-known Mindererus spirit, combined with antimonial or ipecacuan wine, are highly serviceable in the earlier stages. Later on, with the view of soothing the pain of the cough, and favouring expectoration, mixtures containing squill or tolu, with the addition of some opiate, such as the ordinary paregorics, may be advantageously employed. The use of opium, however, in any form should not be resorted to in the case of young children without medical advice, since its action on them is much more potent and less under control than it is in adults. Not a few of the so-called "soothing mixtures," have been found to contain opium in quantity sufficient to prove dangerous when administered to children; and, indeed, it is to be feared that fatal results not unfrequently follow their incautious use in this way.

From the outset of the attack the employment of warm applications to the chest in the form of fomentations or poultices affords great relief. Few remedial measures are of greater value than the frequent inhalation of steam. This is accomplished readily enough in the case of adults by the use of an inhaler or simply by breathing over an open-mouthed vessel containing boiling water. In children in whom this plan cannot be carried out in the same manner, there is in general no difficulty in surrounding them with an atmosphere of steam by placing around them vessels containing hot water, the vapour from which envelopes them. The relief to the cough and breathing, and the aid to expectoration afforded by this simple plan, are often surprising, and the cases are rare where it cannot be borne.

Should the cough persist for a length of time, and the disease threaten to become chronic, counter-irritant applications to the chest in front and behind, in the form of stimulating liniments, or even of blisters, will be rendered necessary.

When the bronchitis is of the capillary form, the great object is to maintain the patient's strength, and to endeavour to secure the expulsion of the morbid secretion from the fine bronchi. In addition to the remedies already alluded to, stimulants are called for from the first; and should the cough be ineffectual in relieving the bronchial tubes, the administration of an emetic dose of sulphate of zinc or squill may produce a good effect.

During the whole course of any attack of bronchitis, attention must be paid to the due nourishment of the patient; and during the subsequent convalescence, which, particularly in elderly persons, is apt to be slow, tonics and stimulants may have to be prescribed.

Chronic bronchitis may arise as the result of repeated attacks of the acute form, or it may exist altogether independently. It occurs more frequently among persons advanced in life than among the young, although no age is exempt from it.

The usual history of this form of bronchitis is that of a cough recurring during the colder seasons of the year, and in its earlier stages, departing entirely in summer, so that it is frequently called "winter cough." In many persons subject to it, however, attacks are apt to be excited at any time by very slight causes, such as changes in the weather; and in advanced cases of the disease the cough is seldom altogether absent.

The symptoms and auscultatory signs of chronic bronchitis are on the whole similar to those pertaining to the acute form, except that the febrile disturbance and pain are much less marked. The cough is usually more troublesome in the morning than during the day. There is usually free and copious expectoration, and occasionally this is so abundant as to constitute what is termed *bronchorrhœa*.

Chronic bronchitis leads to alterations of structure in the affected bronchial tubes, their mucous membrane becoming thickened or even ulcerated, while occasionally permanent dilatation of the bronchi takes place, often accompanied with profuse fœtid expectoration. In long standing cases of chronic bronchitis, the nutrition of the lungs becomes impaired, and dilatation of the air-tubes (*emphysema*) and other complications result, giving rise to more or less constant breathlessness. Chronic bronchitis is liable in some instances, particularly when accompanied with loss of flesh and strength, to be mistaken for consumption; but the physician who carefully regards the history of the case and observes the physical signs and symptoms, will in general be able to distinguish the one disease from the other.

Chronic bronchitis may arise secondarily to some other ailment. This is especially the case in Bright's disease of the kidneys, and in heart disease, of both of which maladies it often proves a serious complication.

Chronic bronchitis does not often prove directly fatal, nor is it necessarily inconsistent with long life. Its chief danger lies in the tendency to intercurrent acute attacks, particularly in the aged; and in this manner it very frequently causes death.

The treatment to be adopted in chronic bronchitis depends upon the severity of the case, the age of the patient, and the presence or absence of complications. Attention to the general health is a matter of prime importance in all cases of the disease, more particularly among persons whose avocations entail exposure, and tonics with cod-liver oil will be found highly advantageous. The use of a respirator in very cold or damp weather is a valuable means of protection. In those aggravated forms of chronic bronchitis, where the slightest exposure to cold air brings on fresh attacks, it may become necessary, where circum-

stances permit, to enjoin confinement to a warm room or removal to a more genial climate during the winter months. When expectoration is attended with difficulty, such remedies as squill in combination with ammonia may prove useful. When, on the other hand, bronchorrhœa exists, astringents are called for. The inhalation of vapour containing iodine or turpentine is often followed with marked benefit in this way. Where breathlessness accompanies the disease, besides the use of ethereal preparations, marked relief is often derived from large doses of iodide of potassium. Counter-irritation to the chest with turpentine, mustard, or croton oil is generally attended with good results. In aged and weak persons stimulants are an indispensable part of the treatment. Acute exacerbations of the disease, which are so apt to arise in the chronic form, must be dealt with on the principles already indicated in treating of acute bronchitis. (J. O. A.)

BRÖNDSTED, Peter Oluf, archæologist, was the son of a Danish clergyman, and was born at Horsens in Jutland on 17th November 1781. He received his academical education at the university of Copenhagen; and in 1802 he visited Paris in company with his friend Koes. After remaining there two years, they went together to Italy. Both were zealously attached to the study of antiquities; and congeniality of tastes and pursuits induced them both, in 1810, to join Baron Stackelberg, Von Haller, and Linckh of Stuttgard, in an expedition to Greece, where they examined with attention the interesting remains of ancient art, and engaged with ardour in excavations among the ruins, which were carried on, especially by Bröndsted and Stackelberg, with very interesting results. The discoveries Bröndsted made were made public in several works, which show learning and sagacity such as have seldom been applied to the elucidation of antiquity with happier results. After three years of active researches in Greece, Bröndsted returned to Copenhagen, where, as a reward for his labours, he was appointed professor of Greek in the university. He now began to arrange and prepare for publication the vast materials he had collected during his travels; but finding that Copenhagen did not afford him the desired facilities, he exchanged his professorship for the office of Danish envoy at the papal court in 1818, and took up his abode at Rome. He also, in 1820 and 1821, went to Sicily and the Ionian Isles to collect additional materials for his great work; and when the artistic illustrations were completed, he obtained leave to visit Paris to superintend the publication. In 1826, he came over to London, chiefly with a view to study the Elgin marbles and other remains of antiquity in the British Museum, and became acquainted with the principal archæologists of England.

He returned to Copenhagen in 1832, when he immediately received the appointment of director of the royal museum of antiquities, and the professorship of archæology and philology. His merits were ten years afterwards further rewarded with the honourable office of rector of the university; but an unlucky fall from his horse caused the death of this eminent man on the 26th June 1842. His principal work was the *Travels and Archæological Researches in Greece*, published in German and French, 1826–30. His dissertations on points of ancient art are very numerous.

BRONGNIART, Alexandre, a distinguished French mineralogist, was the son of the eminent architect who designed the Bourse and other public buildings of Paris, and was born in that city in 1770. At an early age he joined the army of the Pyrenees; but having committed some slight political offence, he was thrown into prison, and detained there for some time. On his release he was appointed professor of natural history in the Collége des Quatre Nations, and soon after succeeded Haüy as professor in the school of mines. In 1800 he was made director of the Sèvres porcelain factory, in which he revived the almost forgotten art of painting on glass. He did not confine himself entirely to mineralogy, for it is to him that we owe the division of Reptiles into the four orders of Saurians, Batrachians, Chelonians, and Ophidians. In 1816 he was elected into the Academy; and in the following year he visited the Alps of Switzerland and Italy, and afterwards Sweden and Norway. The result of his researches he published from time to time in the *Journal des Mines* and *Dictionnaire des Sciences Naturelles*. He died at Paris, October 7, 1847.

His principal works are—*Traité élémentaire de minéralogie appliquée aux Arts*; the *Tableau des terrains qui composent l'écorce du globe, ou Essai sur la structure de la partie connue de la terre*; and the *Traité des Arts céramiques* 1845. Brongniart was also the coadjutor of Cuvier in the admirable *Essai sur la géographie minéralogique des environs de Paris*.

BRONTE, a city of Sicily in the intendency of Catania. It stands in a healthy situation at the western foot of Mount Etna, on the river Giaretta, near a celebrated waterfall. It has considerable manufactures of linen and woollen cloths, and some paper-mills. Good wine is produced in the neighbourhood. Bronte is of comparatively modern origin, having all been built since the 16th century. It gave the title of duke to Lord Nelson. Population, 14,589.

BRONTE, Charlotte, modern English novelist, was born on the 21st April 1816. Her father, the Rev. Patrick Bronte, was a native of county Down, Ireland; her mother, Maria Branwell, was of Cornish family. At the date of his marriage, in 1812, Mr Bronte held the living of Hartshead in Yorkshire, and there his two eldest daughters, Maria and Elizabeth, were born. In 1815 he removed to Thornton, in the parish of Bradford, where Charlotte, her brother Patrick Branwell, and her younger sisters, Emily and Anne, were born. In 1820 he was presented to the living of Haworth, and removed in that year to the parsonage, a bleak and solitary house, standing close by the churchyard and backed by a wide expanse of moorland. Mrs Bronte died soon after their removal, and the little family of young children were left to educate and train themselves. They saw little of their father, whose health was bad, and who seems to have been eccentric in his modes of thinking and acting. The charge of the little flock devolved upon the eldest daughter, a girl of between seven and eight when her mother died; and, under the peculiar circumstances of their life, the children's intellectual powers and sympathies developed with rapidity. Utterly deprived of all companions of their own age, with none of the usual outlets for their pent-up energies, they lived in a little world of their own. The harsh realities around them, the bleak scenery, the coarse and rugged natures of the few inhabitants with whom they came in contact, only impelled them to construct for themselves an ideal world, modelled after their own strange and untrained imaginations, in which they found satisfaction and reality. By the time Charlotte Bronte was thirteen years of age, it had become her constant habit, and one of her few pleasures, to weave imaginary tales, idealizing her favourite historical heroes, and bodying forth in narrative form her own thoughts and feelings. Nor was she alone in this curious occupation; all the family took part in the composition of juvenile stories and magazine articles. It was a strange training for a child, boding little good for her future happiness when thrown into the ordinary routine of life.

An event which made a deep impression on this strange family circle was the entering of the two eldest girls, in 1824, at a school recently opened at Cowan's Bridge, near Haworth, and intended for daughters of clergymen. A vivid picture of this school, and one which Miss Bronte always maintained was not over-coloured, is presented in *Jane Eyre*, for the Lowood of that story is Cowan's Bridge.

Of all pupils the Brontes were the least likely to fall in well with the requirements of their new mode of life. Everything was novel and repulsive to them; their peculiar natures were repressed and stunted; their intellectual sympathies found no food. Charlotte and Emily became pupils later in the same year, but it was soon found necessary to remove Maria. Her health had given way completely, and she died a few days after her return to Haworth in the spring of 1825. But a few months later and Elizabeth followed her sister to the grave. The younger girls were removed in the autumn of 1825; and Charlotte, as the eldest of the household, took upon herself the duties that Maria had formerly discharged. For six years she remained at home leading the usual quiet, isolated life, and indulging to the full her rare faculty of composition. She then spent one of her happiest years in a school at Roe Head, and some of the acquaintances made there became life-long friends. To this school she returned in 1835 in the capacity of teacher, and for a time her sisters were with her as pupils. After three years her health, always delicate, gave way alarmingly, and she had to be withdrawn to Haworth. Two short experiences as governess in a family having shown her how little such a life was suited to her, she turned her thoughts towards taking a school, a plan which would have had the special advantage of keeping together the three devoted sisters. Some money was advanced for this scheme by their aunt, and it was resolved that, as a preliminary step, Charlotte and Emily should study French upon the Continent. In 1842, accordingly, they found themselves in Brussels, and a new world, a new experience, was opened up to Miss Bronte's vigorous and imaginative mind, a world to be afterwards reproduced in living characters. She studied hard, and before her return to England in January 1844 had acquired a very thorough knowledge of French.

She came back to a home into which a fresh element of unhappiness had been introduced. Her brother Patrick, a youth of fine talents, had fallen into habits of dissipation, which rapidly rendered him a hopeless drunkard. For some years the sisters had the misery of seeing daily before them the spectacle of a wasted life, of powers thrown away, and of opportunities despised. The details of his unfortunate story may well rest in obscurity. He lingered on till September 1848.

Meanwhile, amid their distress, the sisters, who found refuge in their habits of composition, had made their first literary venture. During their separation, while Charlotte was in Brussels, and Anne in a situation as governess, they had been quietly pursuing their favourite occupation; and in 1845 they made the discovery of each other's poetical efforts. After some correspondence with publishers they resolved to print a small volume of poems, assuming the *noms de plume* of Currer, Ellis, and Acton Bell. The book appeared in the spring of 1846, was barely noticed by the reviews, and attracted no public attention. The authors, however, were encouraged to make a further trial, and each began to prepare a prose tale. Charlotte's was *The Professor*; Emily's, *Wuthering Heights*; Anne's, *Agnes Grey*. *The Professor* was refused on all hands; the other two were accepted, but their publication was delayed for some time. Nothing daunted by her want of success, Charlotte devoted herself heart and soul to a new tale, *Jane Eyre*, which she completed in August 1847. The MS. was accepted by Messrs Smith and Elder; the book appeared with the name of Currer Bell on the title page in October 1847, and at once achieved a decided success.

Few works of an unknown author have been received with such sudden and general acclamation. The utter and even paradoxical disregard for the conventional which the book displayed, the masculine vigour and glowing energy with which the main characters were drawn, and its intense realism, at once seized and secured the popular favour, and showed the literary world that a new and powerful competitor for its honours was in the field. Its success was not so much the result of the favourable verdicts of trained judges, for these came but slowly, as of its own intrinsic force. The delineation of the harsh and rugged but powerful northern character was the revelation of a new world, and the intensest interest was excited as to the true name and abode of the unknown author. Numerous were the conjectures as to Currer Bell, but the secret was well kept. Even the publishers were unaware of the truth, till the disclosure had to be made to them in consequence of the publication of *Wuthering Heights* and *Agnes Grey*, and of the announcement of *The Tenant of Wildfell Hall*. The public, however, remained in the dark till after the appearance of the second work by the unknown, when a shrewd Yorkshireman, who knew Haworth, divined the secret and published his discovery.

Shirley, this second work, fully sustained the author's high reputation. Yet it was written under melancholy circumstances. The death of Patrick Bronte, in September 1848, was followed by the deaths of Emily and Anne in quick succession. Emily died on the 19th December 1848; Anne on the 28th May 1849. *Shirley* was published in October 1849. The disclosure of Miss Bronte's name as the writer at once introduced her to the great literary society of London. She met all the most prominent men of letters of the time; yet, though she was in the world, she was not of it. Her previous life and her peculiarly sensitive and retiring disposition made notoriety and attention painful to her, and she gladly escaped to the quiet of Haworth parsonage. Slowly, and with long interruptions from failing health, her last work proceeded to completion. *Villette* was published in 1853, and was hailed with universal delight. It is in some respects the most pleasing of her works, while it at the same time exhibits some of her gravest faults. The description of the life at the foreign *pension*, and the whole delineation of the principal characters, are reflexes of her own experience, and impress one with their vivid reality and truth. The plot, however, is unskilfully constructed, and the interest seems to shift from one set of characters to another in the progress of the story.

In June 1854 Miss Bronte was married to her father's curate, the Rev. Mr Nicholls, and for a brief period she tasted the strange new happiness of domestic life. But the seeds of decay were in her constitution; the same malady that had carried off her sisters, worked its way with fatal facility in her enfeebled frame. She died on the 31st March 1855. After her death *The Professor*, her first luckless tale, was published from her MSS.

A comparison has sometimes been made between Miss Bronte and Miss Austen. The points of contrast are certainly more apparent than the points of similarity; and it is a fact not without significance that Miss Bronte could never thoroughly appreciate the merits of her great predecessor. Both were consummate masters of literary expression, and both finished their work with the utmost care and precision. Miss Austen is distinctly superior in skilful evolution of plot and in the nice adjustment of character and incident. But her figures are tame and lifeless when compared with those of Miss Bronte, and what she chiefly lacked, the fierce glow and fire of imagination, and the perception of depths in human nature only revealed through suffering experience, the other possessed to an almost unrivalled extent. Miss Bronte's experience was, indeed, narrow, but it was of a rare kind, such as was peculiarly adapted to her strong and yet sensitive spirit. She had too what Goethe calls the true secret of poetic genius,

penetration to the individual and real; what she had herself known and felt, the deep impressions made on her mind by wild scenery, and by rugged yet genuine human natures, that she mirrored forth with living truth and fiery vehemence. Doubtless her strength at times approaches too near to coarseness, the situations become almost melodramatic, and the result may be charged with sensationalism, but the pervading sense of intense reality is more than sufficient to carry off these defects.

Of her three great works *Jane Eyre* will always be the one which occurs most readily in connection with her name; it has all the vigour and individuality of a first-born work of genius. *Shirley*, one of the sweetest love-stories in the range of English fiction, abounds in rich humour, but wants the perfection of artistic unity. *Villette* contains, perhaps, more of the author's personality than either of the others. The character of the heroine is in truth that of Miss Bronte herself, and the analysis of it is at times morbidly acute. *The Professor* has never gained much popularity, though the main conception is one of great beauty and is skilfully handled.

Of EMILY BRONTE's works it is somewhat difficult to speak. Hers was a strange nature, not easily understood; and it had but little time to develop. Some of her poems are singularly powerful, and show uncommon abilities. *Wuthering Heights* is a literary curiosity. Unmistakably the work of a strong mind, into which the wild scenery of the north had sunk deeply, it shows absolutely no comprehension of human character. We are transplanted to a dreamland, enveloped in a lurid thunderous atmosphere, through which stalk fantastic giant beings, gloomy and devilish in their utter wickedness. It is the production of a powerful imagination, but of an imagination unrestrained by any experience of the real, and regulated by no considerations of artistic beauty and proportion.

ANNE BRONTE's was a mind of weaker calibre. *Agnes Grey* is a gentle, gracefully written tale, founded on the writer's own experiences of a governess's life; but it manifested little power or promise. *The Tenant of Wildfell Hall* has much greater force and vigour; but the main conception is an unpleasant one over which the writer had brooded until she had been seized with a morbid craving to give it shape and substance. It is a painful story, inartistically told.

Charlotte Bronte's friend, Mrs Gaskell, has narrated her life, as only a woman of kindred genius could. Of Emily and Anne, incomparably the best notice is that prefixed by Charlotte Bronte to the second edition of *Wuthering Heights* and *Agnes Grey*. A new and uniform edition of the whole works of the three sisters, with Mrs Gaskell's *Life* (which first appeared in 1875), illustrated by engravings of the principal places mentioned, is at present (1876) in course of publication.

BRONZE is an alloy formed wholly or chiefly of copper and tin, in variable proportions. It has been used from a very early period. Archæologists distinguish a *bronze age* in prehistoric times in Western Europe (intermediate between those of stone and iron), characterized by a general use of the alloy for cutting instruments and other objects. The "brass" of the Bible was probably of the nature of bronze. The use of bronze in early times is noticed more particularly below.

The addition of tin to copper gives rise to a product more fusible than copper, and thus better suited for casting. The alloy is also harder and less malleable. The proportions in which copper and tin are combined to make bronze vary according to the object for which the alloy is designed. With about 7 parts copper to 1 part tin, bronze is very hard, brittle, and sonorous. Soft bronze, again, which bears drifting, rolling, and drawing, is generally composed of 16 copper to 1 tin; while a flexible tenacious alloy, good for nails and bolts, is made of 20 copper to 1 tin. In preparing bronze for statues, bas-reliefs, &c., the qualities chiefly looked at are fusibility and hardness, also readiness to acquire a fine patina on exposure, though it appears this may be acquired by bronzes differing widely in composition. A common statue bronze is formed of copper 80, tin 20. Bell-metal, for large bells, is generally made with about 3 parts copper to 1 part tin; for house bells, 4 copper to 1 tin. The bronze of bells (as of various other objects) sometimes contains a little zinc, lead, &c., in addition to the primary ingredients. The Chinese *tam tams* or *gongs*, are made of bronze forged by the hammer; they contain about 20 per cent. tin, the rest copper only. The secret of their manufacture seems to have been revealed by MM. Julien and Champion, who find that a bronze of this nature, though at the common temperature brittle as glass, may, at a dull red heat, be forged and beaten out as easily as soft tin. The speculum metal employed in telescopes is of 2 copper to 1 tin; and on the other hand, with larger proportions of copper, we have an alloy suitable for machinery bearings, and also for medals, 8 copper to 1 tin; another for brass ordnance or bronze cannon, 9 copper to 1 tin; another for mathematical instruments, 12 copper to 1 tin, &c. The hardness and resistance to oxidation of bronze fit it admirably for coins, and many ancient bronze coins have come to us but little deteriorated, though buried for ages in damp soil, or immersed in water. The composition of the present bronze British coinage is (in 100 parts) 95 copper, 4 tin, 1 zinc.

A few years ago some very beautiful Chinese and Japanese bronzes were exhibited in Paris, remarkable chiefly for the dead black colour of their patina. From analyses by M. Morin it appeared that they contained a large proportion of lead, the average composition being copper 80 parts, lead 10, tin 4, zinc 2, and the remaining four parts consisting of iron, nickel, arsenic, silver, and gold. According to M. Christofle, lead is not essential for production of a fine black patina; and it renders the alloy brittle. Bronze can be covered with a black, red, brown, or green patina, as desired, by suitable oxidation or sulphurization.

Some important researches on bronze for field-guns have lately been made by Colonel Uchatius of Vienna; and the *steel bronze* he produces is said to be quite equal to steel in hardness, homogeneousness, resistance, and other qualities; while it is less affected by atmospheric agency, and less costly. He casts the bronze (which contains 8 per cent. tin, the rest copper) in a cast-iron ingot mould, with a core of wrought-copper 50 mm. in diameter. Then after boring out the hollow ingot to a diameter of 80 mm. he forces through it a series of six conical pistons of hardened steel, slightly larger in diameter than the bore. The interior is then excessively hard and ready for rifling. The hardness, elasticity, and solidity diminish from within outwards. These new bronze guns have been found to bear several hundred discharges successively without the slightest apparent deformation or other injury.

It is only of late years that the changes produced in bronze by addition of phosphorus have been scientifically investigated; and from experiments by Messrs Montefiore, Künzel, Kirkaldy, and others, *phosphor bronze* is proved to have great superiority to ordinary bronze in tenacity, elasticity, and tensile strength (being to it much what steel is to wrought iron). The presence of oxides in ordinary bronze accounts for its possessing these qualities in less degree, and phosphorus increases them by reduction of the metal. Phosphor bronze is further greatly improved in tensile strength by being drawn into wire or rolled into sheets; and it resists the action of sea-water much better than copper. Such a substance cannot fail to find many important applications, military, industrial, and domestic. In virtue of its reducing properties, we may add, phosphor bronze can be platinized better than any other metal.

The alloy known as *aluminium bronze* is one endowed with great strength, malleability, and ductility. It is formed of 10 parts aluminium and 90 of copper.

In the melting of ordinary bronze, reverberatory furnaces have long been used, as rapid fusion is desirable in order to prevent loss of tin, zinc. or lead by oxidation. Bellfounders often use dome-topped furnaces, as their alloy does not require so intense a heat for fusion; but there is some waste of material with these. The copper is melted first, and covered with small charcoal or coke; and the tin is rapidly thrust down to the bottom of the melted mass. After stirring, the alloy is poured into the moulds, in which the cooling should be as rapid as possible. Sometimes pressure is applied during cooling, in order to make the cast free from pores.

In the old method of bronze-casting, known as the *cire perdue*, wax is first used for the thickness of the statue (between core and mould, which are of baked clay), and is melted and run off before the metal is poured in,—the core and mould being held apart by stays of iron wire. In the present day large works are never cast in one piece, but in several, which are afterwards united by heating and application of fused metal. A model is made in plaster, and a piece mould of Caen sand, about 1½ or 2 inches thick, made round it, the sizes of the pieces being determined by the shape and character of the portions they occupy. These pieces are backed with plaster of Paris to about a foot in thickness, with indentations cut in their horizontal thickness, into which the succeeding portion of the mould fits. The mould is then taken to pieces, dried, and rebuilt in the casting-pit. It is then filled with core-composition in a liquid state, and when this is sufficiently hardened, again taken to pieces. The core thus obtained is thoroughly dried, and reduced in size by scraping away as much of the material as would represent the thickness of the metal to be cast. This done, the mould is again built up over the core, and the pit filled, &c., as in the other process. The statue is completed after its removal from the mould by cutting off the jets, removing roughnesses where they occur, and giving greater sharpness to the details when necessary.

Statues and various ornamental objects may also be manufactured by the process of electro-deposition from a metallic solution; and some excellent results have been obtained in this way by Oudry, Christofle, Elkington, and others. While the method offers some advantages in regard to cheapness, lightness, &c., of the products, the bronzes thus produced are not so hard and durable as those got by casting, and are thus less suited for exposure.

Bronzing is the process by which a bronze-like surface is produced on objects made of metal, plaster, wood, or other material. It may be done variously. The green bronze colour is sometimes produced on metal with vinegar alone, or dilute nitric acid, or sal-ammoniac. To give an antique appearance to newly made articles of bronze or brass, it is recommended to dissolve three-quarters of an ounce of sal-ammoniac and a drachm and a half of binoxalate of potash (salt of sorrel) in a quart of vinegar, moisten a soft rag or brush with the solution, and rub over the clean bright metal till its surface becomes quite dry through the friction. This process should be repeated several times, and the object should be kept a little warm. With a solution of chloride of platinum (which is, however, an expensive liquid) almost any colour can be imparted to copper, brass, iron, or new bronze, according to the degree of dilution and number of applications. The following solution is suitable for bronzing coins and medals:—Two parts of verdigris and one part of sal-ammoniac are dissolved in vinegar, the solution is boiled, skimmed, and diluted with water till it has only a weak metallic taste, and on further dilution lets fall no precipitate. This solution is made to boil briskly and poured on the objects. These are well washed with clean water and then lacquered.

Objects of cast-iron may be made to assume a fine bronze appearance by being coated with a very thin layer of vegetable oil, and then placed in a drying oven, the temperature being such that oxidation of the iron and decomposition of the oil take place simultaneously. Another mode of bronzing iron (lately recommended by Weiskopf) is with a solution of one part sylvate of silver in twenty parts of oil of lavender. The object is lightly coated with this, and warmed rapidly up to 302° C. For bronzing tin or white metal a solution may be used consisting of 1 oz. sal-ammoniac, ½ oz. alum, and ½ oz. arsenic, dissolved in 1 pint of strong vinegar.

A good method of bronzing wood, porcelain, stoneware, composition picture and looking-glass frames, &c., is first to coat the article with a thin solution of water glass, using a soft brush. Bronze powder is then dusted on, and any excess not adherent is knocked off by a few gentle taps. The article is next heated to dry the silicate, and the bronze becomes firmly attached. Bronze powders are prepared of many different shades. In Messrs Brandeis's process the alloy used (generally copper-zinc) is laminated into very fine leaves, which are then ground. The powder is washed out and dried, and by revolving in a box, which contains some mineral varnish, the particles receive a coating of the varnish. Bronze powders are also prepared from leaf gold ground with honey on a stone, mosaic gold ground with bone ashes, compounds of tungsten and soda, and in other ways.

As regards cleansing of bronze statues that have become coated with dirt in large towns, it has been found that a dilute solution of caustic alkalies removes the overlying dirt and allows the green patina to become visible. Where the metal was not originally oxidized, the alkali simply cleanses it and does not promote any formation of green rust. An occasional rubbing with oil (all excess being carefully removed) is also found to preserve a fine bronze surface. The shining brown colour of gun barrels or other arms, is sometimes imparted by first producing a very thin uniform film of oxide or rust on the iron, *e.g.*, with vapour of muriatic acid, and giving a gloss to the surface by rubbing wax over it, or coating it with a shellac varnish. But the most common material for browning is the butter or chloride of antimony, sometimes called *bronzing-salt*. It is mixed with olive oil and rubbed on the iron, which is slightly heated. A little aquafortis is then rubbed on to quicken the operation; the barrel is then cleaned, washed with water, dried and polished, either with a steel burnisher, or by rubbing with white wax, or is varnished with a very weak solution of shellac and spirit of wine. (See Ure's *Dictionary of Arts*, &c.)

Greek and Roman Bronze.

The bronze (Greek, χαλκός; Latin, *æs*) of *classical antiquity* consisted chiefly of copper, with an alloy of one or more of the following metals, zinc, tin, lead, and silver, the quantity and the character of the alloy changing as times changed, or as was required for different purposes. Among existing bronze remains the copper is found to vary from 67 to 95 per cent. At present the only valuable results which we possess are derived from the analysis of coins (Von Bibra, *Die Bronzen und Kupferlegirungen der alten und ältesten Völker*, Erlangen, 1869), from which it appears that for their bronze coins the Greeks adhered to an alloy of copper and tin till 400 B.C., after which time they used also lead with increasing frequency. Silver is rare in their bronze coins. The Romans also used lead as an alloy in their bronze coins, but gradually reduced the

quantity, and under Caligula, Nero, Vespasian, and Domitian, coined pure copper coins; afterwards they reverted to the mixture of lead. So far the words χαλκός and æs may be translated as bronze. Originally, no doubt, χαλκός was the name for pure copper. It is so employed by Homer, who calls it ἐρυθρός (red), αἴθωψ (glittering), φαεινός (shining), terms which apply only to copper. But instead of its following from this that the process of alloying copper with other metals was not practised then, or was unknown to the poet, the contrary would seem to be the case from the passage (*Iliad*, xviii. 474) where he describes Hephæstus as throwing into his furnace, copper, tin, silver, and gold, to make the shield of Achilles, so that it is not always possible to know whether when he uses the word χαλκός he means copper pure or alloyed. Still more difficult is it to make this distinction when we read of the mythical Dactyls of Ida in Crete or the Telchines or Cyclopes being acquainted with the smelting of χαλκός. It is not, however, likely that later Greek writers, who knew bronze in its true sense, and called it χαλκός, would have employed this word without qualification to objects which they had seen unless they had meant it to be taken as bronze. When Pausanias (iii. 17, 6) speaks of a statue, one of the oldest figures he had seen of this material, made of separate pieces fastened together with nails, we understand him to mean literally bronze, the more readily since there exist very early figures and utensils of bronze so made. The earliest employment of bronze for artistic purposes was to hammer it out in thin plates and fasten them together with nails. This process was called *sphyrelaton*. The next stage was casting, in connection with which the earliest Greek artists of fame are Theodorus and Rhœcus of Samos (Pausanias, viii. 14, 8, and x. 38, 5). It has been supposed that their merit consisted in introducing the process of casting statues hollow, that is, with an inner core of some material which could afterwards be removed and leave the figure light, less costly, and no less durable. There are remains of Assyrian bronze, probably older than the time of Theodorus and Rhœcus, cast with an inner core of iron; and there is also in the British Museum an early Etruscan statuette from Sessa on the Volturno, with a core of this metal, which from its being split down the side, owing to the expansion of the iron, shows how unserviceable the iron was for this purpose. Obviously the power of casting in bronze, whether solid or hollow, was a very great gain to sculptors, whose models worked in the clay with the rapidity of their inspiration could thus be accurately and at once reproduced. The difficulty and expense of the process must have been against it as compared with marble; yet it was frequently employed, and in the case of colossal statues it had no rival. Of these the Colossus of Rhodes —a figure of the sun-god Helios, said to have been 70 cubits high—was an example of the utmost that art could do with bronze. It was thrown down by an earthquake after standing fifty-six years. A statue of Zeus at Tarentum by Lysippus was 40 cubits high, and though it could be moved with a touch of the hand, yet it resisted the force of storms by means of a support at the point of the greatest stress. The oldest seat of bronze-founding, at least to any extent, was the island of Delos, and next to that the island of Ægina, and yet copper does not appear to have been found in either. Between the two there existed a rivalry in the time of the sculptors Myron and Polycletus, of whom the former used the bronze of Delos, the latter that of Ægina. More celebrated than either was the bronze of Corinth, which some believed to have been first obtained by the melting together of statues of ordinary bronze, gold, and silver at the burning of that town. Pliny says that it consisted of gold, silver, and copper, and was considered more precious than silver and little less valuable than gold. There were three kinds of it—one white, having almost the appearance of silver, in which silver predominated; another yellow, because of the great quantity of gold in it; and a third in which all three metals were equally represented. But the Corinthian bronze was used rather for drinking cups and utensils than for statues. The process of casting statues as given by Pliny was to bring the mass of copper to a liquid state, and then to throw into it a third part of old bronze and 12½ per cent. of *plumbum argentarium*, *i.e.*, tin and lead in equal parts.

Of the vast number of bronze statues by ancient sculptors nothing beyond a few fragments remain; but if the colossal bronze head of Venus in the British Museum be taken as a typical example, it will show with what fineness and thinness those figures were cast; or, again, as an instance of the quality of Greek bronze we may take the bronzes of Siris, also in the British Museum, on which a very thin plate of bronze will be seen in some parts of the figures beaten out nearly half an inch till it reaches the thinness of note-paper. Works in relief (τόρευμα), whether beaten out or chased, like those just mentioned, or cast, are comparatively rare, though this branch of art was largely practised even by the greatest sculptors. On the other hand, it does not appear to have been carried out by them to the extent in which it is found in Germany and Italy after the beginning of the 11th century,—for instance, in the reliefs on cathedral gates. The temple of Athene Chalkioikos in Sparta, with its walls covered with bronze reliefs, stands out as an exception. By the time of the Byzantine empire, when the power of modelling had declined, and a taste for glittering appearance took its place, the process of ornamenting bronze with reliefs was superseded by inlaying it with silver and other materials. As to the colour of the ancient bronzes little can now be said, because from lying so long in the earth they have become covered with what is technically called a *patina*, which is generally some shade of green, though sometimes also nearly blue, and at other times drab. This blue colour is very brilliant in bronzes from Herculaneum and Pompeii. A difference of soil very probably makes a different patina, but something may also be due to varieties in the alloy. Perhaps the finest examples of patina are to be found among the bronze mirrors, in which there seems to have been generally a considerable quantity of silver for the sake of obtaining a highly reflecting surface. It does not appear that the process of gilding bronze was carried to any extent in classical times, unless, perhaps, in the production of finger-rings, of which a considerable number remain. But if larger works in bronze fail, there is an abundance of statuettes, candelabra, mirrors, *cistæ*, and vessels of all kinds—Greek, Roman, and Etruscan. One fact to be noticed is that the great number of bronze mirrors which exist are nearly all Etruscan. A few may be Roman from the Latin inscriptions which they bear, and a few also come from Greece. But the general rule of their being Etruscan reminds us of the reputation which the Etruscans enjoyed for the production of works in bronze, not of high art, but of what might be called industrial art. They were celebrated also for modelling in clay; and that, as Pliny states, was the stage of art which immediately preceded casting in bronze, and went hand in hand with it.

The art of bronze casting, which had sunk with the Byzantine empire, was again revived with great vigour in Germany in the 11th century, from which period are the bronze gate of the cathedral at Hildesheim (1015) and the column decorated with reliefs on the model of the column of Trajan in Rome (1022). In the 12th century the art spread southward to Italy, and at first was taken up energetically in Lower Italy. But though many interesting works of this kind exist also from the 13th and 14th

centuries, it was not till the 15th that the art obtained its complete mastery under the Florentine artists. In the following century, again, it is found carried with extraordinary skill in Germany at Nuremberg, Augsburg, Munich, and Coburg. Since then, however, the higher order of sculpture in bronze may be said to have reverted to nearly its ancient limits, that is, the production of statues and groups in the round. (See Dr C. Bischoff, *Das Küpfer in der vorchristlichen Zeit*, Berlin, 1865; and L. R. v. Fellenberg, *Analysen von antiken Bronzen*, 1865.)

BROOCH, or BROACH, (from the French *broche*), an awl or bodkin. A spit is sometimes called a *broach*, and hence the phrase "to broach a barrel." The term is now used to denote a clasp or fastener for the dress provided with a pin, having a hinge or spring at one end, and a catch and loop at the other. Brooches were universally used among the more civilized nations of antiquity. They were made of many materials, and in innumerable varieties of ornamental design, the forms varying according to the period of their manufacture, or the taste and culture of the people using them. They are unknown in the Swiss Lake settlements of the Bronze Age, though pins and bracelets are abundant. Brooches of the Bronze Age are extremely rare in Britain, although they occur in considerable numbers and of elegant forms in North Germany and Scandinavia. The simplest is similar to that which has been reproduced in modern times as the "patent safety-pin," but having the ends prolonged into flat spirals and the clasp flattened and engraved with ornamental designs. Another characteristic form was produced by winding a long wire into a flat double-spiral, of which one end formed the pin and the other the catch. A third form consisted of two round ornamented plates connected by a bow-shaped centre piece. In the early Iron Age the brooches of Central Europe exhibit an immense variety of forms, which are for the most part bow-shaped or harp-shaped, with spring-pins, akin to the types found in the Etruscan cemeteries of Certosa and Villanova recently explored. The Frankish group exhibits three well-defined types, viz., an imitation of animal forms, a simple disc, and a cruciform type, of which there are innumerable varieties of form. The Merovingian brooches were made in gold, silver, or bronze, adorned with precious stones, filagree-work, or enamel; but whatever the richness of the brooch, the pin was always of iron. The Scandinavian or Northern group exhibits a similar cruciform variety more massive in form and richly chased, the terminating knobs fashioned into the similitude of animals' heads. This form occurs also in Anglo-Saxon graves in England. The Anglo-Saxon brooches were exquisite works of art, ingeniously and tastefully constructed. In Kent the circular form predominates. They are often of gold, with a central boss exquisitely decorated, the flat part of the brooch being a mosaic of turquoises, garnets on gold-foil, mother of pearl, &c., arranged in geometric patterns, and the gold work enriched with filagree or decorated with dragonesque engravings. Sometimes the brooch was cruciform and ornamented with chased work and settings of paste or precious stones. The Scandinavian brooches of the Viking time were oval and bowl-shaped, formed of an under shell of impure bron[illegible] gilt on the convex side, and covered by an upper shell of open chased-work ornamented with bosses, or open crown-like ornaments, or animals' heads. The geographical distribution of these peculiar brooches indicates the extent of the conquests of the Northmen. They occur in northern Scotland, England, Ireland, Iceland, Normandy, and Livonia. The Celtic group is characterized by the penannular form of the ring of the brooch and the greater length of the pin. They are usually of bronze or silver, chased or engraved with intricate designs of interlaced or dragonesque work in the style of the illuminated Celtic manuscripts of the 7th, 8th, and 9th centuries. The Hunterston brooch, which was found at Hawking Craig in Ayrshire, is a well-known example of this style. Silver brooches of immense size, some having pins 15 inches in length, and the penannular ring of the brooch terminating in large knobs resembling thistle heads, are occasionally found in Viking hoards of this period, consisting of bullion, brooches, and Cufic and Anglo-Saxon coins buried on Scottish soil. In mediæval times the form of the brooch was usually a simple, flat circular disc, with open centre, the pin being equal in length to the diameter of the brooch. They were often inscribed with religious and talismanic *formulæ*. The Highland brooches were commonly of this form, but the disc was broader, and the central opening smaller in proportion to the size of the brooch. They were ornamented in the style so common on Highland powder-horns, with engraved patterns of interlacing work and foilage, arranged in geometrical spaces, and sometimes mingled with figures of animals.

BROOKE, FRANCES, a clever novelist and dramatic writer, whose maiden name was Moore, was born in the earlier part of the 18th century. Of her novels, some of which enjoyed considerable popularity in their day, the most important were *The History of Lady Julia Mandeville, Emily Montague*, and *The Excursion*. Her dramatic pieces and translations from the French are now wholly forgotten. She died in January 1789, two days after her husband.

BROOKE, HENRY, novelist and poet, was born at Rantavan, county Cavan, in 1708. His father was rector of Killinkere; his mother was a daughter of the bishop of Elphin. At an early age he entered Dublin University, where he was noticed by Swift, who predicted great things of him. About 1724 he proceeded to London, where he managed to gain the affection and esteem of Pope. He studied law in the Temple, and in 1728 married his ward and cousin, Catherine Meares, a girl of fifteen. His first literary venture appears to have been the poem *Universal Beauty* (1730), in which there is exceedingly little that can be admired or even tolerated. A much more successful venture was the drama *Gustavus Vasa*. The prohibition of this play induced the author to publish it, and the sale of the printed copies was enormous. Brooke is said to have cleared 1000 guineas by it. In 1740 his health gave way; he retired to Rantavan, and never returned to his life in London. In 1745 he was made barrack-master at Mullingar, and his well-meant pamphlet, *Secret History and Memoirs of the Barracks of Ireland*, excited much ill-feeling against him. He spent the remaining years of his life in literary work. His dramas were numerous, and some of them kept the stage for a considerable length of time. The work by which he is best known, *The Fool of Quality*, began to appear in 1768. It is the product of the matured experience of the author, and though deficient in many of the qualities that go to form the excellence of a work of fiction, it is forcibly and clearly written, and contains much sound and advanced thinking on social problems. Brooke died in 1783. An edition of the *Fool of Quality* was published in 1859 by the Rev. Charles Kingsley, in whose extravagantly eulogistic preface will be found all the information we have with regard to the author's life and character.

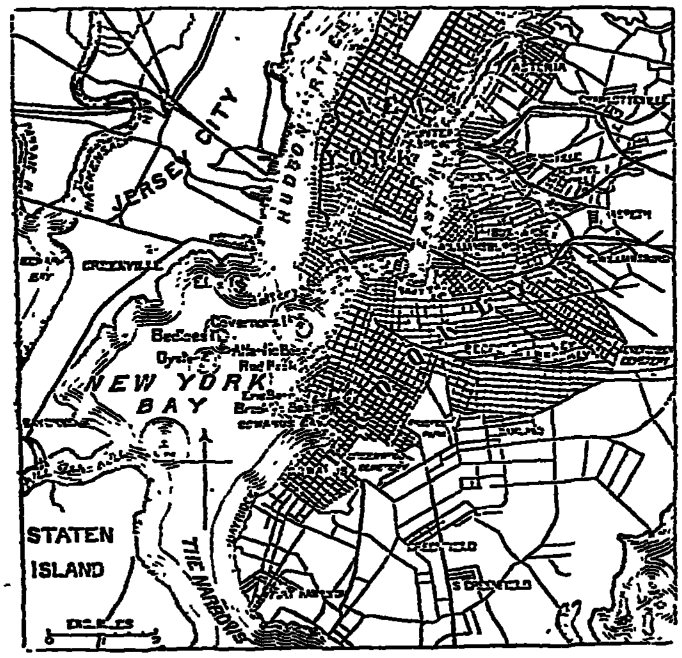
BROOKE, SIR JAMES, Rajah of Sarawak, in the island of Borneo, and Governor of Labuan, was born at Coombe Grove near Bath, April 29, 1803. It is sometimes erroneously stated that he was born in Bengal, a mistake arising from the fact that his father a member of the Civil Service

of the East India Company, had long lived there. His mother was a woman of superior understanding, and to her care he owed his careful early training. He received the ordinary school education, entered the service of the East India Company, and was sent out to India about 1825. On the outbreak of the Burmese war, he was despatched with his regiment to the valley of the Brahmaputra; and, being dangerously wounded in an engagement near Rungpore, was compelled to return home (1826). After his recovery he travelled on the Continent before going to India, and circumstances led him soon after to leave the service of the Company. In 1830 he made a voyage to China, and during his passage among the islands of the Indian Archipelago, so rich in natural beauty, magnificence, and fertility, but occupied by a population of savage tribes, continually at war with each other, and carrying on a system of piracy on a vast scale and with relentless ferocity, he conceived the great design of rescuing them from barbarism and bringing them within the pale of civilization. His purpose was confirmed by observations made during a second visit to China, and on his return to England he applied himself in earnest to making the necessary preparations. Having succeeded on the death of his father to a large property, he bought and equipped a yacht, the "Royalist," of 140 tons burden, and for three years tested its capacities and trained his crew of twenty men, chiefly in the Mediterranean. At length, on October 27, 1838, he sailed from the Thames on his great adventure. On reaching Borneo, after various delays, he found the Rajah Muda Hassim, uncle of the reigning sultan, engaged in war in the province of Sarawak with several of the Dyak tribes, who had revolted against the sultan. He offered his aid to the rajah; and with his crew, and some Javanese who had joined them, he took part in a battle with the insurgents, and they were defeated. For his services the title of Rajah of Sarawak was conferred on him by Muda Hassim, the former rajah being deprived in his favour. It was, however, some time before the sultan could be induced to confirm his title (September 1841). During the next five years Rajah Brooke was engaged in establishing his power, in making just reforms in administration, preparing a code of laws, and introducing just and humane modes of dealing with the degraded subjects of his rule. But this was not all. He looked forward to the development of commerce as the most effective means of putting an end to the worst evils that afflicted the archipelago; and in order to make this possible, the way must first be cleared by the suppression, or a considerable diminution, of the prevailing piracy, which was not only a curse to the savage tribes engaged in it, but a standing danger to European and American traders in those seas. Various expeditions were therefore organized and sent out against the marauders, Dyaks and Malays, and sometimes even Arabs. Captain Keppel, and other commanders of British ships of war, received permission to co-operate with Rajah Brooke in these expeditions. The pirates were attacked in their strongholds, they fought desperately, and the slaughter was immense. Negotiations with the chiefs had been tried, and tried in vain. The capital of the sultan of Borneo was bombarded and stormed, and the sultan with his army routed. He was, however, soon after restored to his dominion. So large was the number of natives, pirates and others, slain in these expeditions, that the "head-money" awarded by the British Government to those who had taken part in them amounted to no less than £20,000. In October 1847 Rajah Brooke returned to England, where he was well received by the Government; and the Corporation of London conferred on him the freedom of the city. The Island of Labuan, with its dependencies, having been acquired by purchase from the sultan of Borneo, was erected into a British colony, and Rajah Brooke was appointed Governor and commander-in-chief. He was also named consul-general in Borneo. These appointments had been made before his arrival in England. The university of Oxford conferred on him the honorary degree of D.C.L., and in 1848 he was created K.C.B. He soon after returned to Sarawak, and was carried thither by a British man-of-war. In the summer of 1849 he led an expedition against the Seribas and Sakuran Dyaks, who still persisted in their piratical practices and refused to submit to British authority. Their defeat and wholesale slaughter was a matter of course. At the time of this engagement Sir James Brooke was lying ill with dysentery. He visited twice the capital of the sultan of Sala, and concluded a treaty with him, which had for one of its objects the expulsion of the sea-gypsies and other tribes from his dominions. In 1851 grave charges with respect to the operations in Borneo were brought against Sir James Brooke in the House of Commons by Joseph Hume and other members, especially as to the "head-money" received. To meet these accusations, and to vindicate his proceedings, he came to England. The evidence adduced was so conflicting that the matter was at length referred to a Royal Commission, to sit at Singapore. As the result of its investigation the charges were declared to be "not proven." Sir James, however, was soon after deprived of the governorship of Labuan, and the head-money was abolished. In 1867 his house in Sarawak was attacked and burnt by Chinese pirates, and he had to fly from the capital, Kuching. With a small force he attacked the Chinese, recovered the town, made a great slaughter of them, and drove away the rest. In the following year he came to England, and remained there for three years. During this time he was smitten with paralysis, a public subscription was raised, and an estate in Devonshire was bought and presented to him. He made two more visits to Sarawak, and on each occasion had a rebellion to suppress. He spent his last days on his estate at Burrator in Devonshire, and died there, June 11, 1868. Notwithstanding differences of opinion with regard to some of Sir James Brooke's proceedings, it is not to be denied that he was a man of the highest personal character. In his public conduct he was undoubtedly actuated by a noble ambition, and he displayed rare courage both in his conflicts in the East and under the charges advanced against him in England. His *Private Letters* (1838 to 1853) were published in 1853. Portions of his *Journal* have also been edited by Captains Mundy and Keppel.

BROOKES, Joshua, English anatomist, was born in 1761. At a very early age he devoted himself to medical science, and attended the lectures of the most eminent surgeons in London and Paris. After he had completed his studies, he began to teach anatomy and physiology, and continued to do so during forty years of his life, training no fewer than 5000 students, many of whom afterwards became famous in different parts of the world. His museum, which contained specimens not only of human and comparative anatomy, but also of natural history in all its branches, was arranged on a system combined from the various methods of Cuvier, Blumenbach, Linnæus, and other naturalists, and cost its proprietor about £30,000. Many of his treatises are printed in the *Transactions* of the various scientific societies of which he was a member. He died suddenly at London, January 10, 1833.

BROOKLYN, a city of the United States of North America, capital of King's County, New York, is situated on the western end of Long Island, immediately opposite the city of New York, from which it is separated by the East River, an arm of the sea, about three-quarters of a mile in breadth. Lat. 40° 41′ N.; long. 73° 59′ W. The city is of very considerable extent, measuring in greatest length

about 7¾ miles, and in greatest breadth about 5 miles; it is 22 miles in circuit, and covers a superficial area of 13,337 acres, or close upon 21 square miles. From Hunter's



Plan of Brooklyn.

Point to Bay Ridge it has a river frontage of nearly nine miles. The ground on which the city is built exhibits considerable inequalities of surface, and thus increases the picturesqueness of its appearance, while the practical disadvantages of such a site have been overcome by skilful engineering. The streets, with the exception of Fulton Street, the principal thoroughfare, are generally straight, have a width of from 60 to 100 feet, and cross each other at right angles. Chief among the public buildings are the city-hall (an edifice of white marble dating from 1845–6), the county court-house (erected in 1862), the county jail (1837), the penitentiary, the state arsenal, and the city hospital. Besides the last-mentioned institution the benevolent establishments of Brooklyn include the Long Island College Hospital, St Mary's and St Peter's hospital, the female orphan asylum, the marine hospital, the Graham institution for the relief of aged women, and numerous other charities. The churches number between 200 and 300, many of them are beautiful buildings, but none claim special notice except the new Roman Catholic Cathedral, which is only rivalled by the corresponding building in New York. Of literary and artistic institutions the most remarkable are the Mercantile Library (dating from 1857), the Brooklyn Institute (founded by Augustus Graham), the Long Island Historical Society, the Art Association, the Academy of Design, the Academy of Music, and the Philharmonic Society. There are three theatres, and an opera house, which dates from 1862. The educational establishments comprise the Packer Collegiate Institute (founded in 1853) for female education, the Polytechnic Institute for boys (started in 1854), the Adelphi Academy for both sexes (founded in 1863), the Roman Catholic College of St John, upwards of fifty public grammar and primary schools, and numerous private institutions. Though Brooklyn in some measure serves as a suburb of residence to New York, and many of its inhabitants carry on their business in the larger city, its own industrial and commercial activity is very great. It has flour-mills, sugar-refineries, lager-beer breweries, distilleries, tobacco factories, and chemical works; and manufactures steel, brass, and copper wares, engines, machinery, and printing-presses. The grain trade is of enormous extent, the warehouses being capable of holding about 12,000,000 bushels; and sugar, coffee, oil, hides, and wool are also largely imported. Most of the river frontage is lined with basins, wharves, and docks, the most important being the Atlantic dock (constructed about 1846) with an area of 40 acres, the Erie basin of 60 acres, the Brooklyn basin of 40 acres, the Wallabout basin, and the United States navy yard. This last occupies a total area of 144 acres, and has extensive wharfage, and a dry dock, built of granite, at a cost upwards of $2,113,000. The city is supplied with water by an elaborate system of reservoirs, of which the most distant is 19 miles away in the vicinity of Hempstead. Its principal pleasure ground is Prospect Park, which embraces more than 600 acres, partly covered with forest trees. A lake of 50 acres is being excavated, and there is a large well 60 feet in diameter, which will furnish the necessary water to keep it fresh. Washington Park, on the site of ancient fortifications, is also a pleasant spot, and there are various other open grounds throughout the city. At the west end is situated the well known Greenwood cemetery, which contains about 520 acres of finely-varied ground, a good part of which is still adorned with natural wood.

The traffic of the city is facilitated by tramway lines; and its conection with New York, which has hitherto been dependent on steam-boat ferries, is to be rendered more convenient by a large bridge in course of construction. This bridge, which crosses the East River near its entrance into New York Bay, is 85 feet wide, and has a river span of 1596 and a total length of 5989 feet. The total cost is estimated to exceed $13,000,000.

The first settlement of Brooklyn, or as it was formerly called Breuckelen, dates from 1636, when a few Walloon colonists took up their residence on the spot that still bears the name of Wallabout (Waalbogt or Walloons' Bay). English and Dutch settlers followed; and in 1667, a patent or charter was granted to the town by Governor Richard Nicolls. The first church had been erected the previous year. In 1698 the population only amounted to 509 persons, of whom sixty-five were slaves. In 1776 the site of the present town was the scene of the battle between the Americans and British, which is usually known as the battle of Long Island. In 1816 Brooklyn was incorporated as a village, and in 1834 it became a chartered city. Williamsburg was founded by Richard W. Woodhull, in the early part of the present century; it attained the rank of a village in 1827, and was recognized as a city in 1851. The population of Brooklyn was in 1800, 3298; in 1820, 7175; in 1830, 15,292; in 1840, 36,233; and in 1850, 96,850. In 1855 the number of inhabitants within the new boundaries was 205,250, of whom 48,367 belonged to Williamsburg; in 1860 this had increased to 266,661, and in 1870 to 396,099, and now (1876) it is estimated at 500,000. (See Stile's *History of the City of Brooklyn*, 3 vols., 1867–70.)

BROOKS, Charles Shirley, an English novelist, and dramatic and miscellaneous writer, was born in 1815. He was the son of an eminent London architect, and received his education at a public school in the city. Applying himself to the study of law, he passed the usual examination for admission; but instead of pursuing further the professional path, he turned aside and began to feel his way towards the broader field of literature. He wrote, sometimes alone, sometimes in conjunction with others, slight dramatic pieces of the burlesque kind, and became a newspaper reporter. In this capacity he was for many years engaged on the *Morning Chronicle*. For the same paper he afterwards undertook to write the parliamentary summary, and was appointed special commissioner to carry out investigations on the subject of labour and the poor. For this purpose he travelled in Southern Russia, Egypt, and Syria; the results of his inquiries appearing first in the form of letters to the editor, and afterwards in a separate volume, under the title of *The Russians of the South* (1856). Brooks was for many years on the staff of the *Illustrated London News*, contributing the weekly article on the politics of the day, and the two series entitled "Nothing in the Papers" and "By the Way," besides other occasional pieces. In 1854 he joined the staff of

Punch, and noteworthy among his numerous contributions were the weekly satirical summaries of the parliamentary debates, entitled "The Essence of Parliament." His long service as newspaper reporter gave him special aptitude for this playful parody. In 1870, on the death of Mark Lemon, "dear old Shirley," as his friends used to call him, was chosen to succeed to the editorial chair. He added to his reputation by several good novels, the first of which, *Aspen Court*, was published in 1855. It was followed by *The Gordian Knot* (1860), *The Silver Cord* (1861), and *Sooner or Later* (1868). Brooks was a great letter-writer, deliberately cultivating the practice as an art, and imitating the style in vogue before newspapers and telegraphs suppressed private letters. He had an astonishing memory, was brilliant as an epigrammatist, and was a great reader, and a most genial and admirable companion. Though he nearly reached his sixtieth year, he retained all the charm of youthful freshness and brightness. He was in his element with a group of children, reading to them, sharing their fun, and always remembering the birthdays. He died in London, February 23, 1874. His remains were interred, near those of his friends Leech and Thackeray, in Kensal Green cemetery. As a novelist Shirley Brooks holds a high rank, but not the highest. His novels probably suffered in some respects from the manner of their production, the slow piece-meal writing for periodical literature. But they possess qualities of an order which will save them from the swift oblivion that overtakes so many books of their class. He shows in them a large knowledge of men, especially of Londoners, a fair acquaintance with the world of books and the world of art, a fertile imagination, and much critical acumen. And these qualities are set off to the best advantage by the charm of an admirably vigorous and polished style. In this respect, and in the force of his refined satire, he bears some likeness to his greater friend, the author of *Vanity Fair*.

BROOME, William, the coadjutor of Pope in translating the *Odyssey*, was born at Haslington in Cheshire, in 1689. He was educated upon the foundation at Eton, and was captain of the school a whole year, without any vacancy occurring by which he might have obtained a scholarship at King's College. Being by this delay superannuated, he was sent to St John's College by the contributions of his friends, and obtained a small exhibition there. His fondness for metrical composition was then such that his companions familiarly called him "Poet." He appeared early in the world as a translator of the *Iliad* into prose, in conjunction with Ozell and Oldisworth, the translation being superior, in Toland's opinion, to that of Pope. Broome was introduced to Pope, who was then visiting Sir John Cotton at Madingley, near Cambridge, and gained so much of his esteem that he was employed to make extracts from Eustathius for the notes to the translation of the *Iliad*, and in the volumes of poetry published by Lintot, commonly called *Pope's Miscellanies*, many of his early pieces were inserted.

When the success of the *Iliad* gave encouragement to a version of the *Odyssey*, Pope, weary of the toil, called Fenton and Broome to his assistance; and taking only half the work upon himself, divided the other half between his partners, giving four books to Fenton and eight to Broome. To the lot of Broome fell the second, sixth, eighth, eleventh, twelfth, sixteenth, eighteenth, and twenty-third, together with the burden of writing all the notes. The price at which Pope purchased this assistance was £300 paid to Fenton and £500 to Broome, with as many copies as he wanted for his friends, which amounted to £100 more. The payment made to Fenton is known only by hearsay; Broome's is very distinctly told by Pope in the notes to the *Dunciad*. It is evident that, according to Pope's own estimate, Broome was unfairly treated. If four books could merit £300, eight, and all the notes, equivalent at least to four more, had certainly a right to more than £600. Broome probably considered himself as injured, for he always spoke of Pope as too much a lover of money, and Pope pursued him with avowed hostility. He not only named Broome disrespectfully in the *Dunciad*, but quoted him more than once in the *Bathos*, as a proficient in the art of sinking. It has been said that they were afterwards reconciled, but their peace was probably without friendship. Broome afterwards published a *Miscellany of Poems*. He never rose to very high dignity in the church; he became rector of Sturston in Suffolk, where he married a wealthy widow; and afterwards, when the king visited Cambridge, in 1728, he was made doctor of laws. In the same year he was presented to the rectory of Pulham. Towards the close of his life he amused himself with translating some of the Odes of Anacreon, which he published in the *Gentleman's Magazine*, under the name of Chester. He died at Bath in 1745. (See T. W. Barlow, *Memoir of William Broome*, 1855.)

BROSELEY, formerly Burwardesley, a market-town on the Severn, in the county of Shropshire, 146 miles from London. It is a place of considerable trade in iron, having near it productive mines of that mineral, as well as of coal. There are also manufactories of tobacco-pipes, bricks, and tiles. Population of parish in 1871, 4639.

BROSSES, Charles de, first president of the parliament of Burgundy, was born at Dijon in 1709. He studied law with a view to the magistracy, but the bent of his mind was towards literature and the sciences. He travelled through Italy in 1739 in company with his friend M. de Sainte-Palaye; and on his return to France published his *Lettres sur l'État Actuel de la Ville Souterraine d'Herculaneum*, Dijon, 1750, 8vo, which was the first work upon that interesting subject. A collection of letters, written during his Italian tour, entitled *Lettres Historiques et Critiques*, in three vols. 8vo, was published at Paris after his death. In 1760 he published a dissertation, *Sur le Culte des Dieux Fétiches*, 12mo, which was afterwards inserted in the *Encyclopédie Méthodique*. At the solicitation of his friend Buffon, De Brosses undertook his *Histoire des Navigations aux Terres Australes*, which was published in 1756, in two vols. 4to, with maps. It was in this work that M. de Brosses first laid down the geographical divisions of Australasia and Polynesia, which were afterwards adopted by Pinkerton and succeeding geographers. In 1765 appeared his *Traité de la Formation Mécanique des Langues*, a work distinguished by much research, and containing an admirable exposition of the purely empirical theory of the origin of language. Full recognition of its merits will be found in Dr Tylor's work, *Primitive Culture*. M. de Brosses had been occupied, during a great part of his life, on a translation of Sallust, and in attempting to supply the lost chapters in that celebrated historian. At length in 1777, he published *L'Histoire du Septième Siècle de la République Romaine*, 3 vols. 4to, to which is prefixed a learned life of Sallust, reprinted at the commencement of the translation of that historian by De Lamalle. These literary occupations did not prevent the author from discharging with ability his official duties, nor from carrying on a constant and extensive correspondence with the most distinguished literary characters of his time. In 1758 he succeeded the Marquis de Caumont in the *Académie de Belles Lettres*; but he was never admitted a member of the French Academy, in consequence, it is said, of the opposition of Voltaire.

Besides the works already mentioned, he wrote several memoirs and dissertations in the collections of the Academy of Inscriptions, and in those of the Academy of Dijon. He also contributed various articles to the *Dictionnaire Encyclopédique*, on the subjects of grammar, etymology,

music, &c., and he left behind him several MSS., which were unfortunately lost during the revolution. He died in 1777.

BROUGHAM, HENRY, first Lord Brougham and Vaux, man of letters, man of science, advocate, orator, statesman, and Lord High Chancellor of England, was born at Edinburgh on the 19th September 1778, and died at Cannes in France on the 7th May 1868. During a great portion of a life extended to the unwonted term of ninety years, but especially in the third and fourth decades of the present century, from 1820 to 1840, no Englishman in any civil career played so conspicuous a part in public affairs or enjoyed so wide a fame as Henry Brougham. His indomitable energy, his vehement eloquence, his enthusiastic attachment to the cause of freedom, progress, and humanity, to which he rendered so many signal services, caused him to be justly regarded as one of the most extraordinary and illustrious men of his age and of his country. He brought to all he undertook a vigour and variety of intellect almost unparalleled; for his ambition was to excel in all things, and he seemed to aspire to universal fame. "There go," said Mr Rogers, as he drove off one morning from Panshanger, "Solon, Lycurgus, Demosthenes, Archimedes, Sir Isaac Newton, Lord Chesterfield, and a great many more in one post-chaise." No man ever commanded with more effect the applause of listening senates, or could better rouse the depths of popular enthusiasm. His boundless command of language, his audacity, his memory stored with every sort of knowledge, his animal spirits and social powers, gave him the lead everywhere, and he was not slow to take advantage of his splendid talents and acquirements in every mode of life. His striking and almost grotesque personal appearance added to the effect of his voice and manner;—a tall disjointed frame, with strong bony limbs and hands, that seemed to interpret the power of his address; strange angular motions of his arms; the incessant jerk of his harsh but expressive features; the exquisite modulations of his voice, now thundering in the loudest tones of indignation, and now subdued to a whisper which penetrated to the very walls of the House of Commons and riveted the attention of the audience; a power of mingling tenderness and scorn, argument and invective, in sentences which rose in accumulated involutions, but righted themselves at last, all contributed to give him the magical influence which a great actor exerts over a crowded theatre. Yet in the midst of all his triumphs, the companions of his early life and those who were best acquainted with his character, knew that his extraordinary gifts and powers did not include all the elements of true greatness. He wanted that moral elevation which inspires confidence and respect, and which is even more essential than genius to the highest achievements and the most lasting fame. At times his eccentricity rose to the verge of insanity, as if the reins by which he guided his fiery temper had slipped from his hand. At the bar there were greater and better advocates; on the bench there were more sure and learned judges; in science he made no real discoveries; in letters, notwithstanding the prodigious activity of his pen, he has left no work of lasting celebrity; and although as an orator he was in his best days unequalled, he himself outlived the evanescent glories of his eloquence. Hence it has come to pass, that within fifty years of his most brilliant period, and within ten years of his death, the figure of Lord Brougham has already become somewhat indistinct. The generation which was fascinated by his eloquence and amused by the endless coruscations and evolutions of his character is passing away, and it has become a task of difficulty to preserve a faithful record of so strange and wonderful a phenomenon. That, however, which remains, and must ever remain as the noblest memorial of his life, is his unvarying devotion to the progress of liberal opinions, to the reform of the law, to popular education, to the emancipation of the negro race from slavery, and to the maintenance of peace. In this sense, he was, as he was once portrayed by an accomplished caricaturist of the day, a citizen of the world. Of every human right, Brougham was a champion; of every human wrong, an avenger.

We shall not attempt in this notice of his life to follow the innumerable incidents of his long and varied career, or to enumerate the speeches and writings which he threw off like sparks on every imaginable occasion. Our object is rather to convey to the reader a just impression of the man, as he appeared to those who knew him as he was, and who still recall the transcendent effects of his energy. Lord Brougham has been unfortunate in his biographers. The memoir of him prepared by Lord Campbell, and published after the death of the author and of the subject of it, is written in a carping and derisive tone, unworthy of a distinguished rival. Lord Brougham's autobiography, which also appeared after his death, was begun when he had passed his eightieth year; his faculties were impaired, his memory was failing, and the work is full of inaccuracies, which his successors were not authorized to correct. Yet we are indebted to it for some interesting particulars of his early life, which no one but himself could have preserved.

In his later years, after Lord Brougham had taken his seat in the House of Peers, he was wont to trace his paternal descent to Udardus de Broham, in the reign of Henry II., and some memorials of that doughty crusader still decorate the baronial hall at Brougham. He claimed, besides, an infusion of pure Norman blood from Harold, Lord of Vaux in Normandy, whose title he added to his own. But these were the delusions of an enthusiastic mind. No real connection has been established between the ancient lords of Brougham Castle, whose inheritance passed by marriage from the Viponts into the family of the De Cliffords, and the Broughams of Scales Hall, from whom the chancellor was really descended. Brougham Hall was purchased from one James Bird by Brougham's great-granduncle, who left it to his grandfather, an active attorney and agent to the duke of Norfolk for his grace's Cumberland property. His father, Henry Brougham, was sent to Eton, and afterwards travelled on the Continent. The sudden death of a young lady to whom this gentleman was about to be married, deeply affected him: he started in 1777 for a short tour in Scotland, but as fate would have it he never recrossed the border or revisited Brougham. In Edinburgh he took lodgings at the house of Mrs Syme, the widow of a clergyman, and a sister of Principal Robertson, the historian. This lady had a daughter of singular beauty and merit. Mr Brougham fell in love with her and agreed to settle in Edinburgh as a condition of obtaining her hand. They were married by Dr Robertson, and in the following year the eldest son, the illustrious subject of this notice, was born at No. 21 St Andrew Square. No feeling in life was more deeply rooted in the heart of Lord Brougham than his intense affection and veneration for his admirable mother. He repaid her early care and judicious guidance by the most ardent and unvarying devotion. He willingly laid all the triumphs of his career at her feet; and she lived to see him attain the proudest heights of fame and power. Nor was he less attached to the memory of his great uncle, the principal. To his dying day he would retrace with affectionate emotion the influence that accomplished scholar and excellent man had upon his own education. He well remembered his person and his precepts, for Dr Robertson only died in 1793, and nearly seventy years afterwards Lord Brougham, presiding over the Social Science meeting at Glasgow, was touched by

hearing a "paraphrase," by his great kinsman, sung in Glasgow cathedral, the authorship of which was probably known only to himself. His parentage on his mother's side being Scotch, and Scotland the place of his birth and education—and, indeed, of his entry into life—he naturally retained many Scottish peculiarities of manner and intonation; yet Brougham was not a Scotchman, he was somewhat eager to throw off his Scottish character, and he said in after life that there was no place he should visit so unwillingly as Edinburgh.

Early life

From his earliest age Brougham showed signs of extraordinary talents and energy. His mother averred that he spoke distinctly several words when he was eight months and two weeks old. In his cradle he was the terror of his nurses, and as he grew older his grandmother compared him to the admirable Crichton from his excelling in everything he undertook. When barely seven he was sent to the High School of Edinburgh, where he gained a triumph over Luke Fraser, his tutor, by successfully justifying the use of some Latin words which Fraser had condemned in an exercise, and in August 1791, when he was not yet thirteen, he left the school as *dux*, or head of the fifth form, taught by the headmaster, Dr Adam. He entered the university of Edinburgh in the winter of 1792, and in addition to the study of Greek under Professor Dalzell, he applied himself to the natural sciences under Professor Playfair, and especially to mathematics. At twelve one of his cousins met him with a huge quarto under his arm, which turned out to be Laplace's *Mécanique Céleste*, in French. In the mathematical class he hit upon the binomial theorem before he had been taught it; and he was soon conversant with the *Principia* of Newton. It was characteristic of his astonishing memory that he carried with him through life all he had learned in boyhood. We have seen him in later years vary the monotony of a legal argument by working a problem in algebra, or exchanging a Greek epigram with Lord Wellesley, in the midst of grave debates of politics or of laws. In 1794 he set to work to master the fluxional calculus; and in the following year he sent a paper to the Royal Society on some new phenomenon of light and colours, which was printed in the *Transactions* of that learned body. A paper on porisms was published in the same manner in 1798, and in 1803 his scientific reputation was so far established that he was elected a fellow of the society. But these efforts were more remarkable for their precocity than for their novelty. In spite of his taste for mathematical reasoning Brougham's mind was not an accurate or exact one; and his pursuit of the physical sciences was rather a favourite recreation than a solid advantage to him. He continued his experiments in optics through life, however, and would sometimes impart observations, which he took for discoveries, to the French Academy of Science. An enthusiastic discourse on Newton and the Newtonian philosophy was written by him in his eighty-fifth year, when a statue of the great philosopher was erected at Grantham, and at that age he was still fond of commenting upon the *Principia*.

But whilst Henry Brougham was following lectures in every branch of knowledge at the university, his inherent animal spirits and sociable nature made him the ringleader of the gayest and wildest youths of the time. Practical jokes, wrenching knockers, braving the watch, and wasting the small hours of the night, were pastimes as familiar to him as the gravest discussions. "Looking back," says he, in his *Memoirs*, "to these pranks reminds me of the inexhaustible fund of spirits one possessed, and how that capital foundation of never-tiring energy and endless restlessness enabled some of us to work on with unfailing strength to the end of life; and even now, writing at nearly ninety years of age, I can recall them—not boys' but young men's freaks—with pleasure and even exultation; yet I agree with the old beggar Ochiltree, in the best of all Scott's works, saying—'Aye, aye! they were daft days thae, but they were a' vanity and waur.'" The spirit of these "daft days," these mad-cap hours, clung to Brougham through life; and long after he had held his great seal of England, perhaps while he held it, he was just as ready to play his part in scenes of the wildest merriment as he had been at the university.

As early as 1792 he founded a debating society of a very juvenile character, to which several persons afterwards distinguished in life belonged. This society, however, subsequently merged in the "Speculative Society," which had a hall and library of its own in the college. Here Brougham, Horner, Jeffrey, Cockburn, Murray, and Moncreiff tried their early powers, and gave the promise of that eloquence which eventually placed them all in Parliament or on the bench of justice. Brougham surpassed them all, not, indeed, in depth of knowledge or soundness of reasoning, but in the astonishing flow of his language, his readiness in reply, the grace of his elocution, and his withering gift of sarcasm and ridicule. Of all the remarkable powers he possessed that of oratory was unquestionably the first. Conscious of his natural strength and of the advantages to be derived from this faculty in a country which is largely governed and swayed by rhetoric, he applied himself with peculiar zeal to the *art* of public speaking. He made himself perfectly conversant with the great masterpieces of ancient eloquence, which he knew to a great extent by heart; he ever maintained that the highest effects of the orator could only be achieved by diligent preparation and constant study; he bestowed extreme care upon the modulation of his voice, which was one of extraordinary compass and strength; even his gestures and attitudes were the result of thought, and it was remarked that in concluding the elaborate peroration of his speech on the queen's trial, he assumed the majestic bearing with which a minister of the Scottish Church invokes the blessing of God in dismissing his congregation. Both by study and by practice, then, oratory was his chief art, and he continued through life to cultivate it with the enthusiasm of an actor, who never entirely attains to the fulfilment of his own ideal. No doubt, in the resistless torrent of his invective, in appeals to the passions of his audience, in the rapid and lucid exposition of facts, in the skilful arrangement of his discourse, which was highly artificial, and in the power of wielding enormous and intricate sentences, Brougham was unrivalled. He entered the House of Commons, as we shall presently see, soon after the voices of Pitt and Fox had been hushed for ever. Except Canning, there was no one in Parliament who could be compared to Brougham, and he rapidly rose to a height of distinction which became at one moment supremacy. Yet on looking back, even to the most celebrated and successful of his efforts, subsequently revised and published by himself, little remains which can lay any claim to the dignity of classic eloquence. Notwithstanding Lord Brougham's study and enthusiastic admiration of Demosthenes, nothing was more unlike the stern simplicity and grandeur of the great Athenian—"*Densus, et brevis, et semper instans sibi*"—than the declamation of Lord Brougham. The force of the current was wasted in a flood which overleapt its banks and broke its barriers. The effect was more intense than permanent. Even in the judgment of his own contemporaries, Canning surpassed him in wit; Plunket in felicity of diction; Lyndhurst in terseness, policy, and cogency of argument; Ellenborough in dignity: but none of them possessed his marvellous versatility, and it seemed as if he had borrowed from each of these great speakers a share in some gift, which they possessed in higher perfec-

Oratorical powers

al lies.

tion than himself. Of all the branches of human knowledge to which Brougham directed his attention, and in which he attained to more or less proficiency, the study of the law was the least congenial to him. He speaks of it in early life as "the cursedest of all cursed professions," and even in 1808, when he had come to England and acquired a certain degree of fame, he writes to Lord Grey: "Odious as that profession is (as God knows there are few things so hateful), I am quite clear that it would be folly in me to neglect so certain a prospect." He added that he was setting out on the Northern Circuit with too slender a provision of law,—his stock of practice being so small that he had never yet seen a *nisi prius* trial,—but thought he might push through the thing with a little presence of mind and quickness. Fortunately for his future career, he had followed for two years the lectures of the professor of civil law in the university of Edinburgh; and, as Lord Campbell admits, so far *legalized* his mind that he had gained a considerable insight into both Roman and feudal jurisprudence. These seeds of law, implanted in a powerful intellect, gave him a breadth of view not always combined with the technicalities of the English bar.

On the 23d May 1800 he was admitted to the Faculty of Advocates. It does not appear that he ever held a brief in the Court of Session, but he went a circuit or two, where he defended or prosecuted a few prisoners, and played a series of tricks on the presiding judge, Lord Eskgrove, which almost drove that learned person to distraction. The Scottish bar, however, as he soon perceived, offered no field sufficiently ample for his talents and his ambition. He resolved to transfer himself to London. He had already appeared as junior counsel in a Scotch appeal to the House of Lords. In 1803 he was entered at Lincoln's Inn, and on the 22d November 1808 he was called to the English bar by that learned society. It is a curious indication of the importance already attached to him as a party man, that the Tory attorney-general and the solicitor-general of the day thought it worth while to come down to Lincoln's Inn to endeavour to oppose his special call, which had been asked for, but was defeated by a single vote. He was called in the ordinary course in the ensuing term.

dinburgh Review.

In this interval of time, however, he had struck a fresh vein which ensured to him power, popularity, celebrity, and for the time a subsistence. The *Edinburgh Review* was founded in the autumn of 1802, under circumstances which have often been related, by the young and aspiring lights of the northern metropolis. The polished style and judgment of Jeffrey, the wit of Sydney Smith, the wisdom of Horner, were suddenly brought to bear on the literature and politics of the day, and amongst them all Brougham was the most ready, the most versatile, the most satirical, and eager to fly at any game which might be on foot. To the first four numbers of the *Review* Brougham contributed twenty-one articles; to the first twenty numbers eighty articles, wandering through every imaginable subject—science, politics, colonial policy, literature, poetry, surgery, mathematics, and the fine arts. The article on Lord Byron's *Hours of Idleness*, which stung the poet into a satirist, and gave the world *English Bards and Scotch Reviewers*, was attributed to his pen; and Lord Cockburn used to relate that on one occasion Brougham wrote off an entire number, including one article on the operation of lithotomy and another on the music of the Chinese. What, however, was of more importance to the youthful author and to the world, was that Brougham stood henceforth indissolubly pledged to the cause of the Liberal party, and to those principles of progress and reform to which he was destined to render so many signal services. The *Edinburgh Review* is the standard of that cause, and Brougham never rested until he had planted it on the loftiest battlements of the fortress. The prodigious success of the *Review*, and the power he was known to wield in it, made him a man of mark from his first arrival in London. He was welcomed at Holland House. He obtained the friendship of Lord Grey and the leading Whig politicians. His wit and gaiety made him an ornament of society, and he sought to extend his literary reputation by the publication of an elaborate work on the colonial policy of the empire. But his hopes of obtaining a seat in Parliament were not yet realized. He was still eating his commons at Lincoln's Inn. He was still in search of a career. Thus it fell out that, in 1806, Mr Fox being then Secretary of State, he was appointed secretary to a mission of Lord Rosslyn and Lord St Vincent to the court of Lisbon, with a view to counteract the anticipated French invasion of Portugal. The mission lasted two or three months; it led to no results. Brougham came home out of humour and out of pocket; and meantime the death of Mr Fox put an end to the hopes of the Whigs and to the broad-bottomed administration. The party to which Brougham had attached himself remained out of office for three-and-twenty years.

Remo. Londo.

Brougham was disappointed by the abrupt fall of the ministry, and piqued that his Whig friends had not provided him with a seat in Parliament, the more so as some of his early friends and rivals were already launched on their political career. Nevertheless, he exerted his pen with prodigious activity during the election of 1809; and Lord Holland declared that he had filled the booksellers' shops with articles and pamphlets. The result was small. No seat was placed at his own disposal. He was too poor to contest a borough; and Perceval and Eldon obtained a majority greater than the majorities of Addington or Pitt. Fortunately for Brougham two questions at this time arose, which gave him a strong hold on the feelings and commercial interests of the country; and he was not slow to take advantage of them and lend them all the support of his energy and genius. When he entered public life the abolition of the slave-trade was well-nigh carried by the untiring exertions of Wilberforce, Thornton, Clarkson, Macaulay, and others. An immense organization had been formed, more especially by the Quakers and other nonconformists, to bring the whole force of public opinion, awakened by the call of humanity and justice, to bear upon the horrors of a system which was still defended by the West India interest and the Government. Brougham allied himself to the leaders of this movement, and he remained through life not only faithful, but passionately attached to the cause. He combated, in and out of Parliament, every attempt to elude the restrictions on the trade in man. One of the first measures he carried in the House of Commons was a bill to make the slave-trade felony. He laboured incessantly to induce foreign countries to abolish the abhorred traffic, and he had at length the happiness, as Chancellor of England, to take a part in the final measure of negro emancipation throughout the British colonies. These services endeared him to a class of highly conscientious and influential persons, with whom he might not otherwise have been closely connected, and their support was of no small effect on the greatest triumph of his life, his election for the county of York in 1830.

Slave-trade.

Although till 1808 Brougham had no practice at the English bar, he had argued some Scotch appeals in the House of Lords and some prize cases at the "Cock-pit." He had acquired some knowledge of international law, and some experience of the prize courts. This circumstance probably led to his being retained as counsel for the Liverpool merchants who had petitioned both Houses of Parliament against the Orders in Council, framed in retalia-

Orders in Council.

tion for the Berlin and Milan decrees. Brougham conducted the lengthened inquiry which took place at the bar of the House, and he displayed on this occasion a mastery over the true principles of political economy and international law which at that time no one else possessed. It seems incredible (though even now the delusion is not entirely dissipated) that the Government of a great commercial nation should ever have thought that one of the most effectual and essential modes of carrying on war and destroying an enemy is to shut out the trade of neutrals, not perceiving that such measures react with at least equal force against ourselves, and destroy the very sinews by which the burden of war can be sustained. The trade of the country was in truth suffering more from these fatal restrictions than from the war itself; and nothing in the whole collection of Lord Brougham's harangues is more forcible or more ably reasoned than the speeches in which he described those sufferings, and denounced the cause of them.

Nevertheless, in 1808, he was unsuccessful. Neither the evidence taken during a six months' inquiry nor the eloquence of the impassioned advocate prevailed. It was not until 1812, when Brougham was himself in Parliament, that he resumed his attack on the Orders in Council with increased authority and vigour, aided by Mr Baring, and still more, perhaps, by the peril and disgrace of the quarrel with America, and he ultimately conquered. No answer was made to his great speech on that occasion, except an intimation from the Treasury bench that the Orders in Council would be revoked. Of this great triumph Brougham afterwards said: "It was second to none of the efforts made by me, and not altogether without success, to ameliorate the condition of my fellow-men. In these I had the sympathy and aid of others, but in the battle against the Orders in Council I fought alone."

ia-
tary

It was considered imprudent and impossible that a man so gifted and so popular as Brougham had now become should remain out of Parliament, and by the influence of Lord Holland, the duke of Bedford was induced to return him to the House of Commons for the borough of Camelford. He took his seat early in 1810, having made a vow that he would not open his mouth for a month. The vow was kept, but kept for that month only. He spoke on the fifth March in condemnation of the conduct of Lord Chatham at Walcheren, and he went on speaking for the rest of his life. In four months, such was the position he had acquired in the House that he was regarded as a candidate for the leadership of the Liberal party, then in the feeble hands of George Ponsonby. Some little time before a squib of infinite drollery was published in the *New Whig Guide*, by Lord Palmerston, under the significant title of "Trial of Harry Brougham for Mutiny." The mutiny consisted in his calling the Right Honourable George Ponsonby an "old woman." When the negotiation took place in 1812 between the Prince Regent and Lords Grey and Grenville for the formation of a Whig Government, it was expected that the presidentship of the Board of Trade would be accepted by Brougham, who was not unwilling to quit the bar altogether for political office. But this gleam of parliamentary success and official anticipation soon vanished. The Tories continued in power. Parliament was dissolved. Camelford had passed into other hands. Brougham was induced to stand for Liverpool with Mr Creevy against Canning and General Gascoyne. The Liberals were defeated by a large majority, and what made the sting of defeat more keen was, that another seat was speedily provided for Creevy, whilst Brougham was left out in the cold. He remained out of Parliament during the four eventful years, from 1812 to 1816, which witnessed the termination of the war, and he did not conceal his resentment against the Whigs.

Brougham's position at this time was difficult and anomalous. Burning with political ambition, and conscious that he had no superior in the arena of the House of Commons, he had lost his seat in Parliament; he was distrusted and feared by some of the leading members of the Liberal party, and, as he said himself in a letter to Lord Grey, "it is their pleasure to consider me as flung overboard to lighten the ship." Yet he stood aloof, not only from the extreme views of demagogues like Hunt and Cobbett, but also from the milder radicalism of Hobhouse and Burdett. Indeed, it deserves to be remarked, that fond as Brougham was of popular applause, and deeply imbued as he was with Liberal opinions, he never condescended to flatter the Radical party or to ally himself with them: but, on the contrary, when in later years differences arose between himself and the Whigs, he leaned rather to the Conservative side, and he was uniformly opposed to any measure which might overthrow the balance of the constitution.

But in the years he spent out of Parliament occurrences took place which gave ample employment to his bustling activity, and led the way to one of the most important passages in his life. He had been introduced in 1809 by Lord Dudley and Sir William Drummond to the society of the Princess of Wales, whose house at Kensington, and afterwards at Blackheath, was the resort of the most agreeable society in London. Canning, Granville Leveson, Dudley, Rogers, and Luttrell were constantly there. But it was not till 1812 that the princess consulted him on her private affairs, after the rupture between the Prince and the Whigs had become more decided. From that time Brougham, in conjunction with Mr Whitbread, became one of the princess's chief advisers; he was attached to her service, not so much from any great liking or respect for herself, as from an indignant sense of the wrongs and insults inflicted upon her by her husband. We shall not attempt to follow the details of these deplorable transactions, which are fully related elsewhere, but one memorable scene, as related by Lord Brougham, cannot be passed over in silence. The Princess Charlotte, irritated and alarmed by her father's threats to break up her household and to marry her to the Prince of Orange, escaped in July 1814 from Warwick House, flung herself into a hackney coach in Cockspur Street, and drove to her mother's residence in Connaught Place. Mr Brougham, who was dining with a friend, was immediately sent for, and on his arrival, half asleep from fatigue, found with extreme surprise what had occurred. The duke of Sussex, the duke of York, Lord Chancellor Eldon, the bishop of Salisbury, and others subsequently arrived, but except the royal dukes, none of these personages were admitted to an audience. Brougham, a young barrister of thirty-six, became and remained the chief adviser of this young princess of eighteen, the heiress to the crown. His advice to her was, —"Return at once to Warwick House or Carlton House, and on no account pass a night elsewhere." The debate was long and painful; the grievances of the princess were numerous. At length, as day began to dawn, Brougham took her to the window, and pointing to the empty street and park, said, "In a few hours these thoroughfares will be crowded. I have only to show you from this window to these multitudes, they will rise in your behalf; Carlton House will be attacked; troops will be called out; blood will be shed; and whatever be the result, it will be known that your running away was the cause of this mischief. You would never get over it." This remonstrance prevailed, and the princess returned to Carlton House with her uncle the duke of York at five in the morning. This anecdote is so graphically told by Lord Brougham in several places that we preserve it. But it has not been corroborated by any of the other persons present; and in a letter written by Brougham himself to Earl Grey on the following day, he said nothing of this touching appeal, but relates that the princess went back because the duke of York came, armed with full powers from the Regent to fetch her away. It is not improbable that the scene thus described is apocryphal, or at least embellished by Lord Brougham's imagination, for in his later years he was apt to mistake for actual occurrences the creations of his own fancy.

Adviser of Princess of Wales.

In 1814, the Princess of Wales, having been prohibited by Queen Charlotte from attending the drawing-rooms given to the allied sovereigns on their visit to England, resolved to go abroad. This unfortunate scheme was strongly opposed by the Princess Charlotte, and not less so by Mr Whitbread and Mr Brougham. The latter addressed a letter to the Princess of Wales on the eve of her departure, in which he pointed out with great sagacity and good sense the fatal consequences of her withdrawal from England. "As long as you remain in this country," he said, "I will answer for it that no plot can succeed against you. But if you are living abroad, surrounded by the base spies and tools who will always be planted about you, ready to invent and swear as they may be directed, who can pretend to say what may happen? I declare, I do not see how a proposition hostile to your Royal Highness's marriage could be resisted if you continued living abroad." How completely these predictions were fulfilled is sufficiently known. Brougham appears to have had but little correspondence with the princess during her residence in Italy. But in 1820, when she resolved to return to England on the accession of George IV., he was sent by the Government conjointly with Lord Hutchinson, to dissuade her from that step and to offer her terms. Brougham certainly disapproved of her return; but for some mysterious reason he withheld the proposed terms of compromise until it was too late, and when they were laid before the queen at St Omer she rejected them with scorn. The death of Mr Whitbread and of the Princess Charlotte, which had occurred in the interval, had removed two important checks on the rashness of the queen; and Brougham, who had failed to prevent her from going away, was equally unable to prevent her return. It has even been surmised that, from a love of mischief and of power, he desired it.

Meanwhile Brougham had at length, in 1816, been again returned

to Parliament for Winchelsea, a borough of the earl of Darlington, and he instantly resumed a commanding position in the House of Commons. He succeeded in defeating the continuance of the income tax; he distinguished himself as an advocate for the education of the people; and on the death of Romilly he took up with ardour the great work of the reform of the law. It has taken half a century to work out the plans of these early law reformers, and the last year or two have given us a national system of education and a new judicature with an entirely new form of procedure. But not the less glorious and valuable were the services of those who first engaged in these great tasks. Nothing exasperated the Tory party more than the select committee which sat, with Mr Brougham in the chair, in 1816 and the three following years, to investigate the state of education of the poor in the metropolis. The inquiry was extended so far as to include the great collegiate foundations of Eton, Winchester, and the Charter House; and the report of the committee was attacked with great virulence by Bishop Monk in the *Quarterly Review* and by Sir Robert Peel in the House of Commons. In time, however, the exposure of abuses bore fruit, and we owe to it some of the most important improvements of the age. Brougham, however, was as far as ever from obtaining the leadership of the party to which he aspired. Indeed, as was judiciously pointed out by Lord Lansdowne in 1817, the opposition had no recognised efficient leaders; their warfare was carried on in separate courses, indulging their own tastes and tempers, without combined action. Nor was Brougham much more successful at the bar. The death of George III. suddenly changed this state of things. Queen Caroline at once, in April 1820, appointed Mr Brougham to be Her Majesty's attorney-general, and Mr Denman her solicitor-general. They immediately took their rank in court accordingly; and, indeed, this was the sole act of royal authority which marked the queen's brief and unhappy reign. In July Her Majesty came from St Omer to England; ministers sent down to both Houses of Parliament the secret evidence which they had long been collecting against her; and a bill was brought into the House of Lords for the deposition of the queen and the dissolution of the king's marriage. The long repressed spirit of opposition in the nation against a bigoted and tyrannical Government was inflamed to a conflagration by the sense of the queen's wrongs. Guilty or innocent (and no one could dispute the excessive levity of her conduct), she was regarded by the people of England as a persecuted woman, a deserted wife, an outraged mother; and these charges were brought against her by those who were guilty of far greater offences. "My mother would not have been so bad," the Princess Charlotte is reported to have said, "if my father had not been much worse." Themes such as these, worked upon by the eloquence of Brougham and the activity of the queen's friends, produced a popular commotion, which in any other country would have caused bloodshed, and perhaps revolution.

The defence of the queen was conducted by Brougham, assisted by Denman, Lushington, and Wilde, with equal courage and ability. He hurled back defiance on the prosecutors, and threatened, if driven to the last extremity, to retaliate on the person of the sovereign: though if he had set up the marriage of the Prince with Mrs Fitzherbert as a valid marriage (which it certainly was not), he would thereby have annulled the subsequent marriage of his royal client. He demolished piece by piece with merciless severity the whole fabric and tissue of Italian evidence, raked together and paid for by the Milan commission; and he wound up the proceedings by a speech of extraordinary power and effort. The peroration was said to have been written and rewritten by him seventeen times. At moments of great excitement such declamation may be of value, and in 1820 it was both heard and read with enthusiasm. But to the calmer judgment of another generation this celebrated oration seems turgid and overstrained. The truth is, that there were moments in the course of the trial when the evidence pressed so hardly on the queen that her counsel were on the point of throwing up the case. But a generous feeling, impelled by an immense popular sympathy, prevailed. It was certain the bill could never pass the House of Commons, where the same appeals might be made to a less judicial assembly. The final majority in the Lords dwindled to nine; and Lord Liverpool announced that he should not proceed with the bill.

This victory over the court and the ministry raised Henry Brougham at once to the pinnacle of fame. He shared the triumph of the queen. His portrait was in every shop window. A piece of plate was presented to him, paid for by a penny subscription of peasants and mechanics. With his wonted disinterestedness in money matters, he refused to accept a sum of £4000 which the queen herself placed at his disposal. He took no more than the usual fees of counsel, while his salary as Her Majesty's attorney-general remained unpaid, and was discharged by the Treasury after her death. But from that moment his fortune was made at the bar. His practice on the northern circuit instantly quintupled. One of his finest speeches was a defence of a Durham newspaper which had attacked the clergy for refusing to allow the bells of the churches in Durham to be tolled on the queen's death; and by the admission of Lord Campbell, a rival advocate and an unfriendly critic, he rose suddenly to a position which no man has before or since attained to in the profession. The meanness of George IV. and Lord Eldon refused him the silk gown to which his position at the bar entitled him, and for some years he led the circuit as an outer barrister, to the great loss of the senior members of the circuit, who could only be employed against him. His practice rose to about £7000 a year, but it was again falling off before he became Chancellor.

The death of Lord Castlereagh in 1822, and the advancement of Canning to the office of Foreign Secretary, materially changed the character of Lord Liverpool's Government. Canning and Brougham sat on opposite benches—the one a follower of Pitt, the other of Fox; and they were constantly pitted against each other. Sometimes their rhetorical conflicts assumed an intense violence, as when Brougham accused the minister of "the most monstrous truckling for the purpose of obtaining office that the whole history of political tergiversation could furnish." Canning indignantly exclaimed, "It is false;" and the quarrel was with some difficulty appeased, though Brougham was not supposed to be very ready to employ any weapon sharper than his tongue. But Canning and Brougham were in truth rivals rather than antagonists; and the more liberal influence of the former in the ministry had almost brought them into union upon the leading questions of the day, always excepting that of parliamentary reform. Had Canning lived and maintained himself in power, it might have fallen to his lot to carry Catholic Emancipation and a more moderate measure of parliamentary reform. But if, as is believed, Earl Grey was excluded from Mr Canning's Government by an express stipulation of the king, it follows *a fortiori* that the attorney-general of Queen Caroline could never be a minister of George IV. That sovereign had shown on several occasions that the attacks made on him by Brougham were never forgotten or forgiven; and Canning, whose own position at court was difficult enough, had certainly not the power to overcome the king's resentment. Brougham, however, promised and gave his shortlived administration an independent support—unlike Lord Grey, who fiercely and ungenerously attacked it.

University of London.

To this period of his life belong two occurrences which cannot be passed over in silence. In 1825 the first steps were taken, under the auspices of Brougham, for the establishment of a university in London, absolutely free from all religious or sectarian distinctions, a scheme which has grown and ripened in half a century into no unworthy rival of the other universities of northern and southern Britain. In 1827 Brougham contributed to found the "Society for the Diffusion of Useful Knowledge,"—an association which gave an immense impulse to sound popular literature. Its first publication was an essay on the "Pleasures and Advantages of Science," written by himself. One can hardly imagine at the present time with what avidity this paper was read, for it had no novelty of substance and no great merit of style. But a thirst for knowledge seemed suddenly to have seized the nation. It broke forth in mechanics' institutes and every form of instruction. To use his own language on a celebrated occasion—"the schoolmaster was abroad;" and the excitement he had contrived to kindle on these subjects tended to hasten a great crisis in our political life. In the following year (1828) he delivered his great speech on "Law Reform," which lasted six hours in the delivery in a thin and exhausted House,—a marvellous effort,—which embraced every part of the existing system of judicature, and concluded with one of his noblest perorations. "It was the boast of Augustus," he said, "and it formed part of the glory in which his early perfidies were lost, that he found Rome of brick and left it of marble,—a praise not unworthy of a great prince, and to which the present reign

S. D. U. K.

also has its claims. But how much nobler will be the sovereign's boast, when he shall have it to say that he found law dear and left it cheap; found it a sealed book, left it a living letter; found it the patrimony of the rich, left it the inheritance of the poor; found it the two-edged sword of craft and oppression, left it the staff of honesty and the shield of innocence!"

The death of Canning, the failure of Lord Goderich, and the accession of the duke of Wellington to power, again changed the aspect of affairs; but the resolution of ministers to carry Catholic Emancipation disarmed the Opposition, whilst it split the Tory party. Graver events were impending. The French Revolution of 1830, following close upon the death of George IV., awakened a passionate excitement throughout Europe, and especially in this country. The days of Tory government were numbered. The cry of "Reform" was raised; and the leader to "ride the whirlwind and direct the storm" was Henry Brougham. Then it was that the united county of York spontaneously returned him to the new House of Commons as their representative. It was the proudest moment of his life, for he was literally not only the representative of the county of York, but of the people of England. A stranger by birth to that great province, and without an acre of land in it, he, by his talents, eloquence, public services, and love of freedom alone, triumphed over the proud Yorkshire families, and took his seat in the House of Commons with a power no Englishman of this age has possessed. The Parliament met in November. Brougham's first act was to move for leave to bring in a bill to amend the representation of the people; but before the debate came on the Government was defeated on another question; the duke resigned, and Earl Grey was commanded by William IV. to form an administration.

ember r York.

hig inistry.

Amongst the difficulties the new premier and the Whig party had to encounter and to surmount, none was greater than that arising from the position, the attitude, and the talents of Mr Brougham. He was not the leader of any party; he had no personal following in the House of Commons; he was distrusted by the Whigs, who looked up to Lord Althorp as their chief; he was dreaded alike by friends and foes; but there stood, in solitary might, the formidable member for the county of York, armed with invincible eloquence, and backed by the suffrages of the people. He himself had repeatedly declared that nothing would induce him to exchange his position as an independent member of Parliament for any office, however great; and, no doubt, as an independent member of Parliament he exercised at that moment a power greater than any office could give. On the day following the resignation of the Government, he reluctantly consented, in low and angry tones, to postpone for one week his motion on parliamentary reform. The attorney-generalship was offered to him by Lord Grey; it was indignantly rejected. Brougham himself affirms that he desired to be master of the rolls, which would have secured him a large income for life, and left him free to sit in the House of Commons. But this was positively interdicted by the king, and objected to by Lord Althorp, who declared that he could not undertake to lead the House with so insubordinate a follower behind him. Meanwhile Brougham had discovered, at a meeting of several leading members of his party at Holland House, that he was not taken freely into their counsels; he came home exasperated and vowing vengeance against them. Lord Grey, personally, would have preferred to retain Lord Lyndhurst as his chancellor; but it was impossible to leave Brougham out, and he was only to be brought into the ministry by the offer of the great seal. When the question was considered at the first meeting of the inchoate ministry at Lansdowne House, Lord Holland said to his colleagues, "I suppose it must be so, but this is the last time we shall meet in peace within these walls." Brougham himself hesitated, or affected to hesitate. He was undoubtedly reluctant to quit the House of Commons and his seat for Yorkshire. His mother, with great wisdom, dissuaded him from accepting these treacherous gifts and honours. He alleged that, as the ministry might be of short duration, he was making a large sacrifice in giving up his professional income for a pension of £4000 a year and a peerage which he had no other means to support. But he yielded to the representations of Lord Grey and Lord Althorp, that without him as Chancellor the Government could not be formed. On the 22d November 1830 the great seal was delivered to him by the king, and he took his seat on the Woolsack that evening as speaker of the House of Lords, being still a commoner. On the following day, after he had sat to hear a Scotch appeal, the patent of his peerage as Baron Brougham and Vaux was brought down. The Lord chancellor then quitted the woolsack, robed, and was introduced as a baron by the Marquis Wellesley and Lord Durham.

Lord Chancellor.

The mind of man can conceive nothing more vivid and more various than the chancellorship of Lord Brougham. It lasted in all exactly four years—no more; but the times were burning with excitement, and the chancellor embodied and expressed the fervour of the times. To rival Lord Bacon in the philosophy of the closet and Lord Hardwicke in the courts of equity, to declaim like Chatham in the House of Lords, and jest like Sheridan at Lord Sefton's dinners, seemed alike easy tasks to Brougham. He never doubted of his own capacity to play every part in turn,—judge, statesman, orator, philosopher, buffoon; and he did play them all with as much success as an imitation can bear to a reality. Unhappily the verdict of time has proved that there was nothing of permanence, and little of originality, in the prodigious efforts of his genius. He affected at first to treat the business of the Court of Chancery as a light affair, though in truth he had to work hard to master the principles of equity, of which he had no experience. His manner in court was desultory and dictatorial. Sometimes he would crouch in his chair, muffled in his wig and robes, like a man asleep; at other times he would burst into restless activity, writing letters, working problems, interrupting counsel. Mortal offence he gave to Sugden, then the leader of the Equity bar, who detested his person and despised his law. But upon the whole Brougham was a just and able judge; and if few of his decisions are cited as landmarks of the law, still fewer of them have been overruled. His wonderful powers of despatch enabled him to work off the arrears of the court in ten months, a thing which had never before occurred in human memory, and in September 1831 he boasted that not a cause remained for hearing before the Lord Chancellor. Yet towards the close of his tenure of office in the spring of 1834, he complained to his colleagues of the tremendous drudgery he had undergone; he had sat up all the nights of winter, he said, to write seventy elaborate judgments, and he conceived that he was ill requited for the sacrifices he had made.

His duties as a judge, however, ranked second in his eyes to his duties as a politician and a legislator; and he took a most active and prominent part in the defence of all the great measures of Lord Grey's Government. We say in the defence of them, for he had less hand in the preparation of them than he wished it to be believed. His own statement that he had called his friends together and submitted to them a complete scheme of parliamentary reform is entirely unsupported, and, indeed, formally contradicted. The draft of the Reform Bill was prepared by a committee of four other members of the Cabinet, and accepted with some hesitation, [illegible]m. But once launched in the contest,

especially in the House of Peers, it owed a great deal to the vigour with which he defended it. The king, William IV., appears at first to have been amused and flattered by the attentions of his chancellor, who made infinite exertions to ingratiate himself with the court. But his manner, which was at first obsequious, became dictatorial; his restless eccentricity and his passion for interfering with every department of state, alarmed and irritated the king, and at last the former liking was turned into bitter aversion.

It would be superfluous in this place to follow the fortunes of the Reform Bill of 1832, and we shall confine ourselves to a brief notice of the part which Lord Brougham took in promoting it. The first grand crisis in the contest occurred in April 1831, when General Gascoyne's amendment was carried against the Government. A cabinet was held, and ministers agreed to advise the king to dissolve Parliament. The king not only assented, but expressed his readiness to go down to Westminster in a hackney coach if necessary. The elaborate narrative communicated by Lord Brougham to Mr Roebuck, and adopted by Mr Molesworth in his *History of the Reform Bill*,—by which it would appear that Lord Grey and the Lord Chancellor resorted to *management* and a species of mild compulsion in making this proposal to William IV., Lord Brougham having taken upon himself to order out the royal carriages and the guards,—is found on more exact inquiry to be unfounded. Unquestionably it was the duty of the prime minister to take the king's pleasure on such an occasion, though the chancellor, contrary to the usual practice, did accompany him, but the whole correspondence of the king on the subject of reform is addressed to Earl Grey alone. The second great crisis in the passage of the bill was in May 1832, when it became necessary to obtain from the king his consent to make peers in sufficient number to carry the bill, if the majority in the Upper House persevered in the attempt to defeat it. It has been stated, apparently on Lord Brougham's authority, that in the course of an audience granted to Lord Grey and himself, he succeeded in extorting from the king, in writing, the following paper:—

"The king grants permission to Earl Grey, and to his chancellor Lord Brougham, to create such a number of peers as will be sufficient to ensure the passing of the Reform Bill,—first calling up eldest sons.

(Signed) WILLIAM R.

"WINDSOR, *May* 17, 1832."

It is enough to say that this extraordinary document has never been seen by any one, and is not known to exist, therefore its exact tenor must be a mystery. The king was not at Windsor on the 17th May, but at St James's; and the Cabinet asked for an assurance of His Majesty's intentions on the following day (the 18th), which they would not have done if a written promise had been given the day before. This story, therefore, is incredible, and in Lord Brougham's autobiography nothing is said of this written paper. Lord Grey and Lord Brougham were both of them strongly averse to the creation of peers, which was fiercely urged on them by some of their colleagues, such as Lord Durham and Sir John Hobhouse. Lord Brougham has even intimated a doubt whether at the last extremity they should have used the power the king had at one time most reluctantly given them. But they both knew that their honour, and possibly their lives, were staked on carrying the bill; and, fortunately, they were relieved from the dire necessity of swamping the House of Lords by the influence of the king and the duke of Wellington over the Tory majority.

It is surprising that Lord Grey's administration, which had achieved so great a work in passing the Reform Bill, and was supported by an immense majority in the reformed Parliament, should so soon have come to an end. But Lord Grey was perpetually threatening to resign office; Lord Althorp longed for retirement; the question of the Irish Church led to the secession of four important members of the Cabinet; the queen was hostile; and the king was alarmed and dissatisfied with the Whig ministers. In July 1834 the crisis arrived, and having carried on the government for three years and 231 days, Lord Grey resigned. Lord Brougham had contrived to monopolize the authority and popularity of the Government, and no doubt his insatiable activity contributed to this result; and there were those who accused him of having intrigued to bring it about, with a view to superseding Lord Grey himself. But this imputation is unjust. Brougham, however, had caused Mr Littleton, the Irish secretary, to suggest to Lord Wellesley, the lord-lieutenant, that some of the clauses in the Irish Coercion Bill might be withdrawn on its renewal, with a view to conciliate O'Connell. Lord Althorp was of the same opinion; but Lord Grey refused to entertain the proposal, and on this rock the ship struck. Brougham declared with great vehemence that it was madness to resign, and that for his own part he had not tendered his resignation. Very much by his exertions the Cabinet was reconstructed under Lord Melbourne, and without Lord Grey; and he appeared to think that his own influence in it would be increased. He laboured at the time under extreme mental excitement,[1] and in this state he unfortunately proceeded to make a journey or progress to Scotland, where his behaviour was so extravagant that it gave the final stroke to the confidence of the king. At Lancaster he joined the bar-mess, and spent the night in an orgy. In a country house he lost the great seal, and found it again in a game of blindman's-buff. At Edinburgh, in spite of the coldness which had sprung up between himself and the Grey family, he was present at a banquet given to the late premier, and delivered a harangue on his own services and his public virtue. All this time he continued to correspond with the king in a strain which created the utmost irritation and amazement at Windsor. He seemed totally unconscious of the abyss which was opening at his feet. He was not the Bacon but the Wolsey of the 19th century.

Fall of Whig ministry.

The term opened in November with the usual formalities. But on the 16th of that month the king dismissed his ministers. The chancellor, who had dined at Holland House, called on Lord Melbourne in his way home, and learned the intelligence. Melbourne made him promise that he would keep it a secret till the morrow; but the moment he quitted the ex-premier, he sent a paragraph to the *Times* relating the occurrence, and adding that "the queen had done it all." That statement, which was totally unfounded, was the last act of his official life. The Peel ministry, prematurely and rashly summoned to power, was of no long duration, and Brougham naturally took an active part in overthrowing it. Lord Melbourne was called upon in April 1835 to reconstruct the Whig Government with his former colleagues. But, formidable as he might be as an opponent, the Whigs had learned by experience that Brougham was even more dangerous to them as an ally, and with one accord they resolved that he should not hold the great seal or any other office. The great seal was put in commission, to divert for a time his resentment, and leave him, if he chose, to entertain hopes of recovering it. These hopes, however, were soon dissipated; and although the late chancellor assumed an independent position in the House of Lords, and even affected to protect the Government, his resentment against his "noble friends"

Later parliamentary labours.

[1] Mr Greville records in his Journal a conversation with Lord Melbourne of the 23d September in this year, from which it is clear that Melbourne was perfectly aware of the state the chancellor was in, and that he hardly thought him of sound mind. He added, "The king can't bear these exhibitions in Scotland."

soon broke out with uncontrolled vehemence. Throughout the session of 1835 his activity was undiminished. Bills for every imaginable purpose were thrown by him on the table of the House, and it stands recorded in *Hansard* that he made no less than 221 reported speeches in Parliament in that year. But in the course of the vacation a heavier blow was struck. Lord Cottenham was made Lord Chancellor. The breach had manifestly become irreparable. Even Lord Brougham's buoyant and daring spirit sunk for a time under the shock. A dreadful period of depression succeeded to the wild frenzy of the preceding years, and during the year 1836 the voice of Lord Brougham was unheard. He passed the spring and summer in Westmoreland, and avoided all political conversation and correspondence. Fifty-six years of his life were spent, and not much more than twenty of them had been spent in Parliament, where he had earned the most prodigious reputation and influence of modern times. "What is the House of Lords without Brougham?"—we have heard Lord Lyndhurst say—"Brougham *is* the House of Lords." For more than thirty years after his fall he continued to take an active part in its judicial business and in its debates. There was still a power in the tone of that voice, raised as it always was in the cause of peace, humanity, and freedom; but it would have been better for his fame if he had died in the midst of his glory. His reappearance in Parliament on the accession of Queen Victoria was marked by sneers at the Court, and violent attacks on the Whigs for their loyal and enthusiastic attachment to their young sovereign; and upon the outbreak of the insurrection in Canada, and the miscarriage of Lord Durham's mission, he overwhelmed his former colleagues, and especially Lord Glenelg, with a torrent of invective and sarcasm, equal in point of oratory to the greatest of his earlier speeches. But why pursue the painful narrative of these writhings of a wounded spirit and a broken ambition? Without avowedly relinquishing his political principles, Brougham had estranged himself from the whole party by which those principles were defended. Flattered, and not unwilling to be flattered, by the Tories, he fought side by side with Lyndhurst, and paid the most fulsome court to the duke of Wellington and a long train of women of quality and men of fashion.

Amongst the humorous expedients resorted to in order to keep his name before the public, a false report of his death was sent up from Westmoreland in 1839, which obtained credence from the persons to whom it was addressed. The newspapers published articles on the melancholy event, and in the *Morning Chronicle* Mr Sheil exclaimed—

> "The extravagant and erring spirit hies
> To his confine,"

whilst he paid a just tribute to the splendid talents and services of the deceased.

Judicial services

It is more agreeable to dwell on the judicial services he continued assiduously to render in the Privy Council and the House of Lords. The Privy Council, especially when hearing appeals from the Colonies, India, and the courts maritime and ecclesiastical, was his favourite tribunal. He had practised a good deal before it (or, as he always called it, "the Cock-pit," so named because the cock-pit of Henry VIII. was the site of the present council chamber) when a young man, before he was called to the English bar; its vast range of jurisdiction, varied by questions of foreign and international law, suited his discursive genius. He had remodelled the judicial committee in 1833, and it still remains one of the most useful of his creations; and he at one time aimed at making himself the president of this committee. To this board Lord Brougham devoted for about sixteen years a very considerable amount of time and labour, and many of his most able and elaborate judgments are recorded in the Privy Council reports which have contributed to build up and perfect the modern jurisprudence of India, and to maintain principles of toleration in the Church of England.[1] He ceased to attend the Privy Council in 1850. But he continued to the close of his life to hear appeals in the House of Lords, where his early knowledge of Scotch law was of peculiar value

Second patent of peerage.

In the year 1860, a second patent was conferred upon him by Her Majesty Queen Victoria, with a reversion of his peerage to his youngest brother William Brougham. The preamble of this patent stated that this unusual mark of honour was conferred upon him by the Crown as an acknowledgment of the great services he had rendered, more especially in promoting the abolition of slavery and the emancipation of the negro race. The peerage is thus perpetuated in a junior branch of his family. Lord Brougham's marriage with Mrs Spalding had given him no male heirs, and his only daughter died in early life unmarried.

Retirement at Cannes.

Upon the portal of one of those delightful villas which nestle amongst the olive trees and the carob trees at Cannes, along the shores of the Mediterranean, are inscribed the lines—

> "Inveni portum: spes et fortuna valete.
> Sat me lusistis; ludete nunc alios."

Such was the haven, such the abode, in which Lord Brougham found repose from the triumphs and the disappointments of his agitated existence. The pure and genial air of the South calmed his nerves and perhaps prolonged his life. There he returned with undiminished pleasure to the head-springs of science, philosophy, and literature. His spirits were more equable; his mind more calm; his society charming. There, then, he spent a considerable part of the later years of his life; and there, when the hour of departure came, his remains mingled with the dust. An accident had attracted his attention to the spot about the year 1838. He bought a tract of land; he built on it; and the Villa Louise Eleonore recalled by its name the adored memory of his lost and only child. Cannes, when he first visited it, was little more than a fishing village on a picturesque coast. His choice and his example made it the sanatorium of Europe.

Last years.

The fame of Lord Brougham had long extended far beyond the frontiers of his native land. The generous and lofty sentiments which he clothed in forcible language touched the heart of mankind. But there was something peculiarly congenial to his own mercurial temperament in the life and genius of France. In 1833 the Academy of Moral and Political Science had conferred upon him the high rank of an associate of the Institute. The Academy of Science did not disdain to listen to his demonstrations. The French, with their lively sympathy for brilliant intellectual power, forgave him all his eccentricities. He has been known to *tutoyer* M. Guizot. He once asked the French Government to give him an island with a state prison on it. He would drop in to tea at the Tuileries in his chequered trousers, and sometimes bring a friend with him, utterly regardless of social usages and etiquette. His French, though fluent enough, was as barbarous and dissonant a brogue as ever tortured the ears of a Parisian. Nobody knew what he would do next. After the revolution of 1848 he asked M. Cremieux (in utter forgetfulness of French law) to have him made a French citizen. But friendship in France is warm and tenacious. Lord Brougham had contributed as much as any man to efface old hatreds and to establish a lasting alliance between France and Great Britain. He judged even her faults in a kindly and indulgent spirit; and of all the tributes to his memory which have issued from the press, none is at once more truthful and more

[1] Thus the judgment on the case of Escott *v.* Martin, which established the validity of baptism administered by a Wesleyan minister or a layman, was prepared and delivered by Lord Brougham.

tender than the discourse pronounced by M. Mignet in the Institute of France in honour of their great associate. Upon that southern coast the last days of this veteran combatant in the fields of law and politics were spent. There at Cannes, upon the 7th May 1868, in the ninetieth year of his age, he expired; and if Westminster proffered no sepulture to the greatest orator of our times, he rests, at least, in the spot which had his latest affections.

To what precedes we have little to add, for who can attempt to portray so multifarious, inconsistent, and variable a being? The irritability of his temper and the egotism of his character made him not only formidable as an antagonist but dangerous as a friend. Yet at bottom he had genuine warmth of heart and good nature. He was a devoted son, an affectionate parent and brother; covetous to a degree of power and patronage, but prodigal in the use of it; disdaining money, yet happy to bestow it on others; fond of courting the great, yet not insensible to the sufferings and the sympathy of the humble and the poor. With unbounded self-confidence, he wanted self-control, and at times under the influence of grief, of resentment, of ambition, of disappointment, or of success, he was scarcely accountable for his actions, still less for his language. His imagination conjured up occurrences which had never taken place; and he changed as rapidly as a chameleon, unconscious of the transformation. Hence it came to pass that whilst men marvelled at his astonishing gifts, they ceased to trust his character; and the splendid promise of the morning of his life was overcast before its close.

The activity of Lord Brougham's pen was only second to the volubility of his tongue. He carried on a vast and incessant correspondence of incredible extent. For thirty years he contributed largely to the *Edinburgh Review*, and he continued to write in that journal even after he held the great seal. The best of his writings, entitled "Sketches of the Statesmen of the time of George III.," first appeared in the *Review*. These were followed by the "Lives of Men of Letters and Science" of the same period. Later in life he edited Paley's *Natural Theology*; and he published a work on political philosophy, besides innumerable pamphlets and letters to public men on the events of the day. He published an incorrect translation of Demosthenes's *Oration for the Crown*. A novel entitled *Albert Lunel* was attributed to him. A fragment of the *History of England under the House of Lancaster* employed his retirement, but we think it was published without his name, and certainly without success. In 1838 Messrs Black of Edinburgh published an edition of his speeches in four volumes, 8vo, elaborately corrected by himself. The last of his works was his posthumous *Autobiography*. Yet ambitious as he was of literary fame, and jealous of the success of other authors, he failed to obtain any lasting place in English literature. His style was slouching, involved, and incorrect. Like his handwriting, which was precipitate and almost illegible, except to the initiated, his composition bore marks of haste and carelessness, and nowhere shows any genuine originality of thought. The collected edition of his works and speeches published by Griffin in 1857, and reissued by Black, of Edinburgh, 1872, is the best; and it was carefully revised by himself, with introductions to the different pieces. His autobiography is of some value from the original letters with which it is interspersed. But Lord Brougham's memory was so much impaired when he began to write his recollections, that no reliance can be placed on his statements, and the work abounds in manifest errors. (H. R.)

BROUGHTON, Hugh, a learned scholar and divine, was born at Oldbury in Shropshire in 1549. After receiving the rudiments of his education at a provincial school, he went to Cambridge, where in due time he was chosen a fellow of Christ's College, and took orders in the church. During his career at the university he laid the foundation of the Hebrew scholarship for which he was afterwards so distinguished. From Cambridge he went to London, where his eloquence gained him many and powerful friends. In 1588 he published his first work, "a little book of great pains," entitled the *Consent of Scriptures*. This work was strongly opposed at both the great universities, and the author was obliged to defend it, which he did in a series of lectures. In 1589 he went to Germany, where he frequently engaged in discussions both with Romanists and with the learned Jews whom he met at Frankfort and elsewhere. In 1591 he returned to England, and published an *Explication of the article of Christ's descent into Hell*, which, like his former treatise, elicited a violent opposition. In 1592 he once more went abroad and cultivated the acquaintance of the principal scholars of the different countries through which he passed. Such was the esteem in which he was held, even by his opponents, that he was offered a cardinal's hat if he would renounce the Protestant faith, which, however, he declined to do. On the accession of James he returned to England; but not being engaged to co-operate in the new translation of the Bible then begun, he retired to Middleburg in Holland, where he preached to the English congregation. In 1611 he returned to England, where he died the following year. Some of his works were collected and published in a large folio volume in 1662, with a sketch of his life by Dr Lightfoot, but many of his theological MSS. remain still unedited in the British Museum.

BROUGHTON, Thomas, a learned divine, and one of the original writers in the *Biographia Britannica*, was born at London, July 5, 1704. At an early age he was sent to Eton, where he soon distinguished himself by his acuteness and studious disposition. Being superannuated on this foundation, he removed about 1722 to the university of Cambridge; and, for the sake of a scholarship, entered himself of Caius College. Here two of the principal objects of his attention were the acquisition of the modern languages, and the study of mathematics, under the famous Professor Sanderson. In May 1727, Broughton, after graduating as B.A., was admitted to deacon's orders, and in the succeeding year was ordained priest, and took the degree of M.A. He then removed from the university to the curacy of Offley in Hertfordshire. In 1739 he was instituted to the rectory of Stepington, or Stibington, in the county of Huntingdon. He was soon after chosen reader to the Temple, by which means he became known to Bishop Sherlock, then Master, who conceived so high an opinion of Broughton's merit, that in 1744 he presented him to the valuable vicarage of Bedminster near Bristol, with the chapels of St Mary Redcliff, St Thomas, and Abbot's Leigh annexed. He was afterwards collated by the same patron to the prebend of Bedminster and Redcliff, in the cathedral of Salisbury. Upon receiving this preferment he removed from London to Bristol, where he married the daughter of Thomas Harris, clerk of that city, by whom he had seven children. He died December 21, 1774.

BROUGHTON, John Cam Hobhouse, Lord, an English statesman, was the eldest son of Sir Benjamin Hobhouse, first baronet, and was born at Redlands, Bristol, June 27, 1786. He was educated at Westminster School and Trinity College, Cambridge, where he took his degree of B.A. in 1808. During his residence at Cambridge he became the intimate friend of Lord Byron; and in the summer of 1809 the two friends set out together on a tour in the South of Europe. They visited Spain (then the theatre of the great war with Napoleon), Portugal, Greece, Albania, and Turkey. The winter was spent at

Athens, and in 1810 Hobhouse returned home. In the campaigns of 1813 and 1814 he accompanied the allied armies, and was present at the great battle of Dresden. In the winter of 1816–17 he rejoined Byron in Italy, and they visited Venice and Rome together. Hobhouse had been trained in the Liberal school of politics, and had written pamphlets and review articles in defence of liberal doctrines. He had by this time become what was then contemptuously called a "downright radical." In 1816 he published anonymously a work in two volumes entitled, *The Substance of some Letters written by an English Gentleman Resident at Paris during the last Reign of the Emperor Napoleon.* His aim in it was to correct certain misrepresentations which were current of the events of the Hundred Days. The tone of the book gave great offence to the English Government; and being translated into French was equally offensive to the Government of the Restoration. The French translator and printer were both prosecuted in 1819 for "atrocious libel" on the Government; and were sentenced to fine and imprisonment, the former for twelve months, the latter for six. On 13th December of the same year the speaker's warrant was issued for the arrest of Hobhouse, and he was committed to Newgate. He made an unsuccessful application to Chief-Justice Abbott (Lord Tenterden) for discharge by *habeas corpus*, and he was not liberated till about the end of February. The treatment which he had suffered gave him the prestige of a martyr to the dominant Toryism, and in the eyes of the multitude this was his glory. At the close of 1818 he had contested the borough of Westminster, Sir Francis Burdett desiring him as a colleague, and giving £1000 towards the necessary expenses of his candidature. But he was beaten by his rival, George Lamb, the brother of Lord Melbourne. He now came forward again, and was returned by a large majority (1820). In the first session of parliament he produced a powerful impression, first by his severe speech on the suppression of a Liberal meeting at Oldham, and soon after by the vigorous support he gave to the bill for disfranchising the borough of Grampound. During the next twelve years he was the ardent and courageous advocate of all Liberal measures,—among them, of the repeal of the Test and Corporation Acts, and of Catholic Emancipation. In August 1831 he succeeded to the baronetcy, and six months later was called to office as Secretary for War under the ministry of Earl Grey. In April 1833 he was named Chief-Secretary for Ireland, but lost his seat at the new election. In the following year he was returned M.P. for Nottingham, and received the appointment of Chief-Commissioner of Woods and Forests under Lord Melbourne. Retiring with the Liberal party in the autumn, he resumed office in April 1835 as President of the Board of Control, a post for which he was well qualified, and which he held till September 1841. He was recalled to the same office under the Russell Administration in 1846, and held it till 1852. Meanwhile he had lost his seat for Nottingham and had been returned for Harwich. In 1851 he was raised to the peerage, and from that time showed himself disposed to "rest and be thankful." He gradually ceased to take part in public affairs, and returned to the studies and literary enjoyments of his youth. Lord Broughton published a volume of *Imitations and Translations from the Classics*; an account of his *Journey through Albania and other Provinces of Turkey with Lord Byron*; and *Historical Illustrations of the Fourth Canto of "Childe Harold."* He was also a contributor to periodical literature. In 1828 he married Lady Julia Hay, youngest daughter of the Marquis of Tweeddale, by whom he had three daughters, but no son. His wife died many years before him. Lord Broughton died in London, June 3, 1869. As he left no male issue his peerage became extinct.

BROUKHUSIUS, or BROEKHUIZEN, JAN, a distinguished scholar, born in 1649 at Amsterdam, where his father was a clerk in the Admiralty. His father dying when he was very young, he was taken from literary pursuits, in which he had made great progress, and placed with an apothecary at Amsterdam, with whom he lived several years. Not liking this employment, he entered the army, and in 1674 was sent with his regiment to America, in the fleet under Admiral de Ruyter, but returned to Holland the same year. In 1678 he was sent to the garrison at Utrecht, where he contracted a friendship with the celebrated Grævius; and here he had the misfortune to be so deeply implicated in a duel, that, according to the laws of Holland, his life was forfeited. Grævius, however, wrote immediately to Nicholas Heinsius, who obtained his pardon. Not long afterwards he became a captain of one of the companies then at Amsterdam; and was thus enabled to pursue his studies at his leisure. His company being disbanded in 1697, he received a pension, upon which he retired to a country-house near Amsterdam. He died in 1707, aged fifty-eight.

As a classical scholar, he is distinguished by his editions of Propertius and Tibullus, the former published in 1702, the latter in 1708. His *Carmina* were published at Utrecht, 1684, in 12mo; and in a more handsome form by Van Hoogstraatten, Amsterdam, 1711, 4to. His Dutch poems were also published at Amsterdam, 1712, 8vo, by the same house, with a life prefixed.

BROUSSA, BRUSSA, or BRUSA, in Turkish *Bursa*, a city of Asiatic Turkey, in the province of Anatolia, and capital of the sanjak of Khodavendkiar, is situated in a fertile valley, at the northern foot of Mount Olympus or Keshish Dagh, 57 miles S.S.E. of Constantinople. Its streets are narrow and dark, and its houses are for the most part built of wood; but its numerous minarets give it a magnificent appearance from a distance, and the rich variety of colouring that everywhere meets the eye has a very striking effect. It is abundantly supplied with water, which flows down the middle of many of the streets, and rises every here and there in beautiful fountains. On the top of a rock in the heart of the town stands the ancient citadel, the walls of which date from the 13th century, and are of Greek construction; and on the west side is the Byzantine church of Elijah, which is now known as the Daud Monasteri mosque, and contains the tomb of Orkhan. The most important of the other mosques, the number of which is said to be upwards of 600, are *Oglú Jami*, or the mosque of the three sultans; the *Yeshil Jami*, or the green mosque; and *Ghan Unkiar Jami*, or the mosque of the conqueror. There are also in the town three Greek churches, one Armenian, and several synagogues. Many of its colleges, bazaars, and caravanserais are buildings of considerable importance, and bear comparison with those of Constantinople. Broussa is the seat of a provincial governor, of a mollah or judge, who ranks as third in the kingdom, and of a mufti or spiritual chief. The Greeks and Armenians have each an archbishop in the town. As a commercial city Broussa ranks with the most flourishing in the empire. The town of Gemlik at the head of Mudani Bay, from which it is about 20 miles distant, serves as its port. It manufactures carpets, tapestry, and various kinds of silk goods, the material for the latter being obtained from the mulberry-plantations of the neighbourhood. In 1862 there were no fewer than sixty silk factories belonging to Italians, Frenchmen, and Germans. About a mile and a half from the town are the famous baths of Broussa, which are fed by several mineral springs varying in temperature up to 184°, and from a hill in the vicinity is obtained a good supply of meerschaum clay. The population of Broussa is variously estimated,—by Mostrás (*Dict. Géog. de l'Empire Ottoman*, 1873) in 1863 at 70,000, by Dr C. Sandreczki in 1844 at 60,000, and by Consul Sax at 40,000.

Broussa, the *Prusa* of the classical writers, founded, it is said, at the suggestion of Hannibal, was for a long time the seat of the Bithynian kings. It continued to flourish under the Roman and Byzantine emperors till the 10th century, when it was captured and destroyed by Seif-ed-daulet of Aleppo. Restored by the Byzantines, it was again taken in 1327 by the Ottomans after a siege of ten years, and continued to be their capital till Amurath I. removed to Adrianople. In 1402 it was pillaged by the Tatars; in 1413 it resisted an attack of the Karamanians; in 1512 it fell into the power of Ala Eddin; and in 1607 it was burnt by the rebellious Kalenderogli. In 1833 it was seized by Ibrahim Pasha, and from 1852–55 afforded an asylum to Abd-el-Kader. In modern times it has suffered several times from earthquake and conflagration, especially in 1855.

BROUSSAIS, FRANÇOIS JOSEPH VICTOR, a celebrated French physician, was born at St Malo in 1772. From his father, who was also a physician, he received his first instructions in medicine, and he studied for some years at the college of Dinan. At the age of seventeen he entered one of the newly-formed republican regiments, but ill health compelled him to withdraw after about two years. He resumed his medical studies, and after passing some time in the hospitals of St Malo and Bryt, obtained an appointment as surgeon in the navy. In 1799 he proceeded to Paris, where in 1803 he graduated as M.D. In 1805 he again joined the army in a professional capacity, and served in Germany, Holland, Italy, and Spain. In 1814 he returned to Paris, and was appointed assistant-professor to the Military Hospital of the Val-de-Grace, where he first promulgated his peculiar doctrines. His theory, which strongly resembles that of John Brown, points to excitation or irritation as the fundamental fact in life. He found the principal cause of disease in over-irritation, which, primarily local, extends itself through sympathy to the other organs of the body, as in fever. His lectures were attended by great numbers of students, who received with the utmost enthusiasm the new theories which he propounded. In 1816 he published his *Examen de la doctrine médicale généralement adoptée*, which drew down upon its author the hatred of the whole medical faculty of Paris. By degrees his doctrines triumphed; and were adopted in the writings and practice of the best physicians, and even in the medical school itself, long before their propounder held office in that institution. In 1831 he was appointed professor of general pathology in the academy of medicine, and taught with great applause till his death in 1838. The recent development of physiological science has shown that his theories are but partially true, and are of little value as a general explanation of disease. Of his works, which are very numerous, the most important are the *Examen* and *De l'Irritation et de la Folie.*

BROUSSONET, PIERRE MARIE AUGUSTE, a distinguished French naturalist, was the son of a schoolmaster, and was born at Montpellier in 1761. He was educated for the medical profession, and at the age of eighteen was appointed to fill a professor's chair. Botany seems to have been the science to which he was at first chiefly devoted; and he laboured with much zeal to establish the system of Linnæus in France. With this view, as well as for his own improvement, he went to Paris, and visited the various museums and collections. He next came to England, and was admitted in 1782 an honorary member of the Royal Society. He published at London the first part of his work on fishes, *Ichthyologiæ Decas I.* On his return to Paris he was appointed perpetual secretary to the Society of Agriculture, an office which the intendant Berthier de Sauvigny resigned in his favour. In 1789 he was nominated a member of the Electoral College of Paris, and for some time had the charge of superintending the supply of provisions for the capital. Under the Convention he had to leave Paris, and after some dangers he made his way to Madrid. The enmity of the French emigrants, however, drove him from Spain, and afterwards from Lisbon, where he had sought an asylum. At last he went out as physician to an embassy which the United States sent to the emperor of Marocco; and on this occasion his friend Sir Joseph Banks, informed of his distresses, remitted him £1000. After residing for some time at Marocco, he obtained from the French Directory permission to return to France, and was appointed by them consul at Teneriffe, where he resided for two years. On his return in 1797 he was chosen member of the Institute, and was reinstated in his botanical professorship at Montpellier, with the direction of the botanical garden. He was afterwards elected a member of the legislative body, but died of apoplexy on the 27th July 1807. France is indebted to him for the introduction of the Merino sheep and the Angora goat. None of his works are now of importance.

BROUWER, ADRIAN, a Dutch painter, was born at Haarlem in 1608, of very humble parents, who bound him apprentice to the painter Frank Hals. Brouwer had an admirable eye for colour, and much spirit in design; and these gifts his master appears to have turned to his own profit, while his pupil was half starved. As the result of this ungenerous treatment, Brouwer was frequently brought into low company and dissipated scenes, which he delineated with great spirit and vivid colouring in his pictures. The unfortunate artist died in a hospital at Antwerp in 1640, at the early age of thirty-two, consequently his works are few and rarely met with. The largest collection of his masterpieces is in the picture gallery at Munich.

BROWN, CHARLES BROCKDEN, the first American novelist who acquired an European reputation, and the first American who made literature a profession, was born of Quaker parents in Philadelphia, January 17, 1771. A youth of delicate constitution and retiring habits, he early devoted himself to study; his principal amusement was the invention of ideal architectural designs, devised on the most extensive and elaborate scale. This characteristic talent for construction subsequently assumed the shape of utopian projects for perfect commonwealths, and at a later period of a series of novels distinguished by the ingenuity and consistent evolution of the plot. The transition between these intellectual phases is marked by a juvenile romance entitled *Carsol*, not published until after the author's death, which professes to depict an imaginary community, and shows how thoroughly the young American was inspired by Godwin and Mary Wollstonecraft, whose principal writings had recently made their appearance. From the latter he derived the idea of his next work, *Alcuin*, an enthusiastic but inexperienced essay on the question of woman's rights and liberties. From Godwin he learned his terse style, condensed to a fault, but too laconic for elcquence or modulation, and the art of developing a plot from a single psychological problem or mysterious circumstance. The novels which he now rapidly produced offer the strongest affinity to *Caleb Williams*, and if inferior to that remarkable work in the subtlety of mental analysis, greatly surpass it in affluence of invention and intensity of poetical feeling. All are wild and weird in conception, with incidents bordering on the preternatural, yet the limit of possibility is never transgressed. In *Wieland*, the first and most striking, a seemingly inexplicable mystery is resolved into a case of ventriloquism. *Arthur Mervyn* is remarkable for the description of the epidemic of yellow fever in New York in 1798, which had proved fatal to the author's most intimate friend. *Edgar Huntly*, a romance rich in local colouring, is remarkable for the effective use made of somnambulism, and anticipates Cooper's introduction of the Red Indian into fiction. *Ormond* is less powerful, but contains one character, Constantia Dudley, which excited the enthusiastic admiration of Shelley, who was also deeply entranced by Brown's other romances. "Nothing," asserts Mrs Peacock, "so blended

itself with the structure of his interior mind as the creations of Brown." The two had, indeed, nearly every leading trait in common, although Brown's weak health and narrow circumstances restrained him from carrying his enthusiastic aspirations into practice. Two subsequent novels, designed as representations of ordinary life, proved failures, and Brown betook himself to less ambitious literary pursuits, compiling a general system of geography, editing a periodical, and an annual register, and writing political pamphlets which attracted considerable attention at the time. He died of consumption, February 22, 1810. He is depicted by his biographer as the purest and most amiable of men, and in spite of a certain formality due, perhaps, to his Quaker education, the statement is borne out by his correspondence. As a novelist he ranks very high; he is the precursor of Hawthorne, and hitherto his only American rival. Greatly inferior to Hawthorne in truth of natural description and insight into human character, he surpasses him in narrative and constructive ability. *Wieland* and *Edgar Huntly* especially are thrilling and exciting in the highest degree, while preserved by the constant presence of a psychological problem from degenerating into mere sensationalism. Most of Brown's novels have been reprinted in England, but none recently. His life by his friend Dunlop (Philadelphia, 1815) is a grievous piece of bookmaking, but is interesting from the subject. An edition of his works in 6 vols. was published at Philadelphia in 1857. (R. G.)

BROWN, JOHN, D.D., an English divine and author, was born at Rothbury, Northumberland, in November 1715. He was the son of John Brown, a descendant of the Browns of Coalstown near Haddington, who at the time of his son's birth was curate of Rothbury. He was educated at St John's, Cambridge; and after graduating as B.A. with great distinction, he returned to his father's house at Wigton, received deacon's and priest's orders from Sir George Fleming, bishop of Carlisle, and in 1739 went to Cambridge to take his M.A. degree. In 1745 he distinguished himself as a volunteer, and was soon afterwards appointed one of his chaplains by Dr Osbaldeston, on his admission to the bishopric of Carlisle. It was probably during his residence at Carlisle that Brown wrote his poem entitled *Honour*, inscribed to Lord Lonsdale. His next poetical production was his *Essay on Satire*, addressed to Dr Warburton, to whom it was so acceptable, that he took Brown into his friendship. He also introduced him to Ralph Allen, of Prior Park, near Bath, to whom in 1751 Brown dedicated his *Essay on the Characteristics of Lord Shaftesbury*. In 1754 he was promoted by the earl of Hardwicke to the living of Great Horkesley in Essex, and in the following year he took the degree of doctor of divinity at Cambridge. In this year also he published his tragedy of *Barbarossa*, which, under the management of Garrick, was acted with considerable applause, though it was sharply censured when published. This tragedy was followed by a second, entitled *Athelstane*, which was represented at Drury Lane theatre. This was also well received by the public, but did not become so popular as *Barbarossa*. Among the most remarkable of his other productions are the *Estimate of the Manners and Principles of the Times*, a bitter satire; the *Additional Dialogue of the Dead*, which was a vindication of Chatham's policy; and the *Dissertation on the Rise, Union, and Power, &c., of Poetry and Music*. Dr Brown, who had an hereditary tendency to insanity, and from early life had been subject at times to fits of excessive melancholy, committed suicide on the 23rd of September 1766

BROWN, JOHN, author of the *Self-Interpreting Bible*, was born at Carpow, in Perthshire, in 1722. He was almost entirely self-educated, having acquired a knowledge of Latin, Greek, and Hebrew while employed as a shepherd. He was, for a great part of his life, minister of the Burgher branch of the Secession Church in Haddington, and also discharged the duties of professor of divinity. Though he had not enjoyed the advantages of a regular education, he mastered the classical tongues, as well as several modern and Oriental languages, and gained a just reputation for learning and piety. He died in 1787. The best of his works, which are very numerous, are his *Self-Interpreting Bible* and *Dictionary of the Bible*, works that were long very popular in Scotland. He also wrote a valuable *Body of Divinity*.

BROWN, JOHN, the founder of the Brunonian theory of physic, was born in 1735 at *Lintlaws* or at Preston, Berwickshire. He was originally destined for the employment of a weaver, but the boy's talents attracted the attention of his schoolmaster, through whose endeavours his parents were encouraged to allow him to begin study for the church. At the age of twenty he came to Edinburgh and entered the classes at the university, supporting himself by private tuition. In 1759 he seems to have discontinued his theological studies, and to have begun the study of medicine. He soon attracted the notice of Dr Cullen, who engaged him as private tutor to his family, and treated him in some respects as an assistant professor. Brown, however, thought that Cullen did not advance his candidature for a vacant chair, and the friendship between the two was soon completely broken. In 1780 appeared the *Elementa Medicinæ*, expounding the new, or as it was then called the Brunonian, theory of medicine. The fundamental idea of this theory was the division of diseases into two classes, sthenic and asthenic, the one caused by excess, the other by deficiency of excitement, and the consequent method of treatment by debilitating or stimulating medicines. That Brown's ideas should have excited the discussion they did seems now incredible. Shortly after the publication he obtained the degree of M.D. at St Andrews, and in 1786 he set out for London in the hope of bettering his fortunes. He died of apoplexy in October 1788. A *Life* of Brown by Beddoes was published in 1801. An edition of his works, with notice of his life by his son, W. C. Brown, appeared in 1804.

BROWN, JOHN, D.D., an eminent Scottish divine, son of the Rev. John Brown of Whitburn, and grandson of the Rev. John Brown of Haddington, was born at Whitburn, Linlithgowshire, on the 12th July 1784. He studied at Glasgow university, and afterwards at the divinity hall of the "Burgher" branch of the "Secession" Church at Selkirk, under the celebrated Lawson. In 1806 he was ordained minister of the Burgher congregation at Biggar, Lanarkshire, where he continued to labour for sixteen years with growing popularity. Transferred in 1822 to the charge of Rose Street church, Edinburgh, he at once took a high rank as a preacher. Deficient in imagination and in spontaneity of utterance, he had nearly all the other qualities of a pulpit orator,—a powerful and flexible voice, a presence at once winning and commanding, clear and persuasive reasoning, and a habitual earnestness, rising not unfrequently into fervour. In 1829 he succeeded Dr Hall in the pastoral charge of Broughton Place church, Edinburgh, where his congregation speedily became one of the largest in the city. In 1835 he was appointed one of the professors in the theological hall of the Secession Church, and, great as was his ability as a preacher and pastor, it was probably in this sphere that he rendered his most valuable service to his own denomination and the church at large. He had been the first in Scotland to introduce in his pulpit ministrations what is known as the exegetical method of exposition of Scripture, and he fully availed himself of his position as a professor to illustrate the

method and extend its use. To him probably more than to any other man is due the abandonment of the radically vicious principle of interpretation according to the "analogy of faith," which practically subordinated the Bible to the Creed. To his favourite task of exegesis, which he himself described as the main object of his public life, Dr Brown brought a rare critical sagacity, exact and extensive scholarship, unswerving honesty, and a clear, logical style. His expository works, noted below, have accordingly a permanent value. Dr Brown was naturally of a retiring disposition, but the strength of his convictions forced him to take a prominent part in the chief religious and political discussions of his time. He had a considerable share in the Apocrypha controversy, and he was throughout life a vigorous and consistent upholder of anti-state-church or "voluntary" views. His two sermons on *The Law of Christ respecting civil obedience, especially in the payment of tribute*, called forth by a local grievance from which he had personally suffered, were afterwards published with extensive additions and notes, and are still regarded as an admirable statement and defence of the voluntary principle. In a discussion which agitated his denomination for several years in regard to the nature and extent of the atonement, Dr Brown took a part which led to a formal charge of heresy being preferred against him. In 1845, after the to him peculiarly painful ordeal of a somewhat protracted trial, he was acquitted by the Synod. From that time he enjoyed the thorough confidence of his denomination (after 1847 "the United Presbyterian Church"), of which in his later years he was generally regarded as the leading representative. Dr Brown died on the 13th October 1858.

Dr Brown's chief works were—*Expository Discourses on First Peter* (1848); *Exposition of the Discourses and Sayings of our Lord* (1850); *Exposition of our Lord's Intercessory Prayer* (1850); *The Resurrection of Life* (1851); *Exposition of the Epistle to the Galatians* (1853); and *Analytical Exposition of the Epistle to the Romans* (1857). See *Memoir of John Brown, D.D.*, by John Cairns (1860).

BROWN, JOHN, an American abolitionist, celebrated as the originator of the Harper's Ferry insurrection, was born in Torrington, Connecticut, on the 9th May 1800. Originally intended for the church, he was compelled to give up study for this purpose on account of inflammation in the eyes. He then took up the business of a tanner, which he carried on for twenty years. Not being very successful in trade, he started business as a wool-dealer in Ohio in 1840. Failing also in this he removed to Essex county, New York, in 1849, and began to reclaim a large tract of land which had been granted to him. After two years he returned to Ohio and resumed his business as a wool-dealer. In 1855, with his four sons, he migrated to Kansas, and at once took a prominent position as an anti-slavery man. He became renowned in the fierce border warfare which was carried on for some years in Kansas and Missouri, and gained particular celebrity by his victory at Ossowattomie. About this time he seems to have formed the idea of effecting slave liberation by arming the slaves and inciting them to rise in revolt against their oppressors. As the first step in this scheme, he designed to seize the arsenal of Harper's Ferry, where an immense stock of arms was kept. On the night of the 16th October 1859, he, with a handful of well-armed and resolute companions, overpowered the small guard and gained possession of the arsenal. During the next morning he made prisoners of some of the chief men of the town, but there was no rising of slaves as had been expected. The townsmen, too, recovered from their astonishment at the audacity of the act, and a bold attack was made on the arsenal. Fresh assailants poured in from the country round, and on the morning of the 18th the arsenal was recaptured, and Brown, severely wounded, was taken prisoner. On the 27th October he was tried at Charlestown for treason and murder, and was found guilty. The sentence passed upon him, death by hanging, was carried into execution on the 2d December. His fate made an extraordinary impression on the excited feelings of the Americans, and his name has become a household word among the Abolitionists.

BROWN, ROBERT, the founder of the Brownists, a numerous sect of dissenters in the reign of Queen Elizabeth, was born in 1550. He was the son of Anthony Brown of Tolthorp in Rutlandshire, whose father obtained, by a charter of Henry VIII., the singular privilege of wearing his cap in the king's presence. Robert was educated at Cambridge, and was afterwards a schoolmaster in Southwark. About the year 1580 he began to promulgate his principles of dissent from the Established Church; and the following year he preached at Norwich, where he soon attracted a numerous congregation. His unmeasured assaults upon the Church of England form of government gained for him many followers. His sect daily increasing, Dr Freake, bishop of Norwich, with other ecclesiastical commissioners, called him before them. Being insolent to the court, he was committed to the custody of the sheriff's officer, but was released at the intercession of his relative the Lord Treasurer Burghley. Brown now left the kingdom, and with permission of the States, settled at Middleburg in Zealand, where he formed a church after his own plan, and preached without molestation. The removal of persecution, however, broke up the unity of the party; numerous sects appeared, and Brown soon returned to England. He fixed his residence at Northampton, where, for his indiscreet attempts to gain proselytes, he was cited by the bishop of Peterborough, and, refusing to appear, was finally excommunicated for contempt. The solemnity of this censure, we are told, immediately effected his reformation. He moved for absolution, which he obtained, and from that time became a dutiful member of the Church of England. This happened about the year 1590; and, in a short time afterwards, Brown was preferred to a rectory in Northamptonshire, where he kept a curate, and where he might probably have died in peace; but having some dispute with the constable of his parish relative to the payment of rates, he proceeded to blows, and was afterwards so insolent to the justice, that he was committed to Northampton jail, where he died in 1630, aged eighty. Brown boasted on his death-bed that he had been confined in thirty-two different prisons. He wrote a *Treatise of Reformation without tarrying for any*, and two other pieces, making together a thin quarto, published at Middleburg in 1582. See BROWNISTS.

BROWN, ROBERT, a celebrated botanist, who may be said to be the founder of the modern science of vegetable physiology, and to have placed the natural system of the classification of plants, originally introduced by Jussieu, upon that sure and ever-widening basis on which it has ever since remained. With the exception of the early years of his life his career was uneventful. His private life is little known; and though his researches were familiar to the learned members of nearly all the European and American academies, which numbered him among their members, his very existence, until the journals of the day proclaimed his decease, was almost unsuspected by the fashionable world of the great city in which he had passed upwards of half a century. His biography may be best read in his works,—a very few words sufficing to record the salient points of his life. Robert Brown was the second and only surviving son of the Rev. Jas. Brown, Episcopalian minister of Montrose, by Helen, daughter of the Rev. Robert

Taylor, and was born on the 21st December 1773. He was educated at the grammar school of his native town, where he had as contemporaries, among others less known to fame, Joseph Hume and James Mill. In 1787 he entered Marischal College, Aberdeen, where he soon distinguished himself. Two years afterwards, his father quitting Montrose for Edinburgh, Brown removed to the university of that city, and there continued his studies for several years, but without taking a degree, though destined for the medical profession. In 1791 his father died, and in 1816 his mother; both are interred in the Canongate churchyard, in the burying ground belonging to Bishop Keith. It was about 1790 that young Brown's taste for botany attracted the attention of Dr Walker, then professor of natural history in the university. His first contribution to the science of which he was destined to be so eminent a cultivator was made on the 26th June 1792, in the shape of a paper on the plants of Forfarshire, read before the Natural History Society; the MS. is still contained in the archives of the Royal Physical Society (*Journal of Botany*, 1871, p. 321). During his student days he also discovered many plants new to Scotland, which were communicated to Withering for his *Arrangement of British Plants*.

In 1795 he obtained a commission in the Forfarshire regiment of Fencible Infantry as "ensign and assistant surgeon," and while serving in the North of Ireland steadily pursued his botanical studies, and had the advantage of the companionship of Capt. Dugald Carmichael of Appin, afterwards well known as an investigator of the lower orders of plants. Having occasion to pass several months of 1798 and of subsequent years in London, he studied in the library and museum of Sir Joseph Banks, P.R.S., whose acquaintance he had been fortunate enough to make by the discovery of a rare moss, *Glyphomitrion Daviesii*. The result of this friendly intercourse was that he was recalled from Ireland, and in the summer of 1801 quitted his not altogether congenial medico-military pursuits, to take the more agreeable post of naturalist to the expedition fitted out under Capt. Flinders for the survey of the then almost unknown coasts of New Holland. Ferdinand Bauer, afterwards familiarly associated with Brown in his botanical discoveries, was draughtsman; Wm. Westall was landscape painter; and among the midshipmen was one afterwards destined to rise into fame as Sir John Franklin. The narrative of that expedition is part of the biography of its botanist. In 1805 the expedition returned to England, having obtained, among other acquisitions, nearly 4000 species of dried plants, many of which were new. Brown was almost immediately appointed librarian of the Linnean Society, of which learned body he had been an associate since 1798, and to the presidency of which he afterwards attained. In this position, though one of no great emolument, he had abundant opportunities of pursuing his studies; but it was not until 1810 that the first volume of his great work, in Latin, the *Prodromus Floræ Novæ Hollandiæ et Insulæ Van Diemen*, appeared. It at once revolutionized systematic botany, not only by the great number of new species it described, but also by the novel views of the general affinities of plants which were promulgated in its pages. Almost immediately it took the rank it has ever since maintained as one of the canons of botanical science. Humboldt soon after its publication dedicated his well-known work on the plants of the New World to Brown (*Roberto Brownio, Britanniarum gloriæ atque ornamento, totam Botanices Scientiam ingenio mirifico complectanti*), and long after, in his *Kosmos*, styled him *facile princeps botanicorum*. The *Prodromus* is now rare in its original edition, the author having suppressed it, hurt at the *Edinburgh Review* having fallen foul of its Latinity; it is chiefly known through a German reprint. With the exception of a supplement published in 1830, no more of the work appeared. In 1810 Brown became librarian to Sir Joseph Banks, who on his death in 1820 bequeathed to him the use and enjoyment of his library and collections for life. In 1827 an arrangement was made by which these were transferred to the British Museum, with Brown's consent and in accordance with Sir Joseph's will. Brown now became keeper of this new botanical department, an office which he held until his death thirty years afterwards. Soon after Banks's decease he resigned the librarianship of the Linnean Society, and in 1849 became president, in which office he continued until 1853. His subsequent life was occupied with numerous brilliant discoveries and researches in vegetable anatomy, physiology, and classification; these are familiar to every student, and may be read in any botanical text-book. Long before his death they secured his fame as the first botanist of the day. Honours flowed thickly in upon him. In addition to being a fellow of the Royal Society he received its Copley Medal in 1839. In 1833 he was elected one of the five foreign associates of the Institute of France,—the other competitors, nearly all of whom afterwards attained the same honour, being Bessell, Von Buch, Faraday, Herschel, Jacobi, Meckel, Mitscherlich, Œrsted, and Plana. He was also a member of nearly all the learned societies and academies of this and other countries, D.C.L. of Oxford, LL.D. of Edinburgh, and knight of numerous orders, among others of the Order "pour le Mérite" of Prussia. In the "Academia Cæsarea Naturæ Curiosorum" he sat under the cognomen of Ray.

On the 10th June 1858 he died in the 85th year of his age, in his house in Soho Square, bequeathed to him by Sir Jos. Banks. His place in botanical science has long been fixed; it is not necessary now to discuss it. His works are all standards, being distinguished by their thoroughness and conscientious accuracy, and displaying powers at once of minute detail and of broad generalization, —qualities rarely combined. Indeed, so careful was he in preparing his discoveries for the press that he directed in his will that, should any of his writings be republished, they should be printed *verbatim et literatim*. In private life he was exceedingly modest, and he shrank from notoriety of every kind. Sensationalism and self-seeking he despised; fame came to him unsought. His reserved manner to those not intimately acquainted with him could never make him universally popular; but few will deny his warm-heartedness to his friends, the singleness of his purpose, and the purity of his life. Those who knew him in his most intimate relations bear witness that in mind he was simple, truthful, and upright, and that he was wise and faithful in council.

In 1825–34 Dr Brown's works up to that date were collected and published in four divisions by Nees von Esenbeck, in German, under the title of *Vermischte botanische Schriften* (Leipsic and Nuremberg). In 1866 the Ray Society reprinted, under the editorship of his friend and successor in the keepership of the Botanical Department of the British Museum, Mr J. J. Bennet, his complete writings, the *Prodromus* alone excepted. In these *Miscellaneous Works* (2 vols., with atlas of plates), the history of his discoveries can be best followed. No special biography of him is ever likely to appear, as his career contained few of the elements essential to a continuous narrative of general interest. In the necrologies of the societies and academies which numbered him among their members, there will, however, be found sketches of his life more or less complete.

BROWN, Samuel, chemist, poet, and essayist, was born at Haddington on the 23d February 1817, and died 26th September 1856. He was the son of Dr Samuel Brown, the founder of itinerating libraries, and grandson of the author of the *Self-Interpreting Bible*. In 1832 he entered the university of Edinburgh, and almost from the first devoted himself with passionate enthusiasm to the study of chemistry. The ultimate problems of the science spe-

cially attracted his attention, and he came to be persuaded that elements usually regarded as chemically simple and primary were transmutable into each other. Believing that he could demonstrate this in the case of carbon and silicon, he became a candidate for the chair of chemistry in Edinburgh university in 1843; but he withdrew his application on finding his proof inconclusive. In 1849 he delivered in Edinburgh a series of lectures of great value on the history of chemistry from the earliest times to Lavoisier. In 1850 he published the tragedy of *Galileo*, which had considerable merit. He was also an occasional contributor of articles on general literature as well as on subjects connected with his favourite science to the leading reviews. His time, however, was chiefly spent in his laboratory; and at the date of his death in 1856 he believed that he was within a very little of demonstrating the great fundamental theory in which his own faith had never wavered. Though his work was thus left incomplete, he did enough to entitle him to a place in the foremost rank of those who have cultivated the higher chemistry. An interesting collection of his essays and papers, which display general literary power of a very high order, was published in two volumes in 1858.

BROWN, THOMAS, of facetious memory, as Addison designates him, was the son of a farmer at Shiffnal in Shropshire, and was born in 1663. He was entered at Christ Church College, Oxford, whence he was soon obliged to abscond on account of the irregularities of his life. He was for some time schoolmaster at Kingston-on-Thames, and afterwards went to London, where he had recourse to the usual refuge of half-starved wits—scribbling for bread. He published a great variety of poems, letters, dialogues, &c., full of humour and erudition, but coarse and indelicate. Though a good-natured man, he had the unhappy quality of preferring rather to lose his friend than his joke. He died in 1704, and was interred in the cloister of Westminster Abbey. An incomplete edition of his works was published in 1707, in 4 vols. 12mo.

BROWN, DR THOMAS, one of the most original and subtle of Scottish psychologists, was born on the 9th January 1778, at Kirkmabreck, Kirkcudbright, of which parish his father was the clergyman. In 1780 the family removed to Edinburgh, but he was not placed at any of the schools in that city. At the age of seven he was sent to London, and began his regular education at a school in Camberwell, from which he was soon afterwards removed to Chiswick. At Chiswick he was thoroughly grounded in classics, and began to give promise of great ability, particularly in the department of verse composition, one of his school poems being deemed worthy of insertion in a magazine. He was a boy of a refined, gentle nature, intensely studious, a devourer of literature of all kinds, and much loved by his companions. After attending two other schools at Bromley and Kensington, he returned to Edinburgh, and in 1792 began his course at the university by joining the logic class, then conducted by Professor Finlayson. During the summer of 1793 he made acquaintance with Dugald Stewart's *Philosophy of the Human Mind*, and found himself irresistibly attracted towards metaphysical speculation. He joined Stewart's class, that of moral philosophy, in the following session, and quickly introduced himself to the professor's notice by reading to him a paper of objections to one of his theories, marked by great acuteness and ability. His attendance on the classes at the university seems to have been somewhat desultory; it does not appear that he ever passed through the regular curriculum of arts studies. But he carried on his reading with great vigour, and while still a student made his first appearance in the arena of philosophical disputation. His attention had been drawn towards Darwin's *Zoonomia*, which was then exciting a lively sensation in the literary world. His remarks on this book were published in 1798, and were received with great approval as one of the best and most mature examinations of the theory. His next contribution to literature was an article in the second number of the *Edinburgh Review* on the philosophy of Kant. It is acute, like all that Brown ever wrote, but it shows neither sufficient knowledge nor adequate appreciation of the philosopher it handled. Meantime he had been devoting himself to the study of medicine, having relinquished that of law, to which for a while he had applied. His graduation thesis, *De Somno*, which was thought worthy of being published, is a fine piece of psychologico-medical analysis. A few months later appeared two volumes of his poems, which were not received with much favour. Nor did his later poetical efforts attain much popularity, with the partial exception of the *Paradise of Coquettes*. They all show refined feeling and sweetness of diction, but they are wanting in the elements of true poetry. They are faint echoes of Akenside and Beattie, neither of whom can stand much dilution. Brown's real strength lay altogether in metaphysical analysis, and a favourable opportunity for calling it forth soon presented itself. Some captious objections had been raised against the appointment of the celebrated Leslie to the professorship of mathematics, on the ground that he had approved of Hume's doctrine of causality. The Humian theory was believed to lead inevitably to scepticism and infidelity, and these consequences were, of course, charged upon Leslie. Brown undertook the defence not of Leslie but of Hume, and in his examination of Hume's doctrine showed that in reality the theory was in no way inimical to the interests of true religion or theology. This examination, at first but a pamphlet, swelled out in its third edition (1818) into a bulky treatise, *Inquiry into the Relation of Cause and Effect*, containing not merely a criticism of Hume, but an elaborate theory of the causal relation. This relation Brown regards as nothing but constancy of antecedence and sequence, while at the same time he admits an intuitive belief in the permanency or universality of the causal connection. The work is a fine specimen of Brown's faculty of analysis, which it exhibits in its very best aspect.

As early as 1806 Dr Brown had engaged in practice as a physician, having been received into partnership with Dr Gregory; but though very successful in his profession, he was by nature more strongly attracted towards a literary life. He had twice failed in his application for a professorship in the university of Edinburgh, when in the session 1808–9 he was called upon to deliver a few lectures to the class of moral philosophy, in consequence of the temporary illness of Dugald Stewart. In the following year, Stewart's health still incapacitating him from active exertion, Dr Brown delivered the lectures for the greater part of the session. His success in conducting the class was unequivocal; the enthusiasm of the students was such as one reflects on with a little wonder. They were fascinated not more by the splendid rhetoric of the lecturer than by the novelty and ingenuity of the views presented. In the summer of 1810 it was resolved to appoint Brown as colleague to Dugald Stewart, and in the ensuing session he began his course as professor of moral philosophy. During the few remaining years of his life he published only his poems, but he was busily engaged in preparing an abstract of his lectures to serve as a handbook for the class. His health, never strong, gave way completely under the pressure of his work. A voyage to London, which had been recommended, proved of no avail, and he died on the 2d April 1820, at the early age of forty-two. After his death were published the first part of his proposed text-book, *Physiology of the Human Mind*, and the *Lectures on the Philosophy*

of the Human Mind, 4 vols., of which the *Physiology* is an abstract. The fame achieved by the *Lectures* when published surpassed even what they had attained when delivered. It is no exaggeration to say that never before or since has a work of metaphysics been so popular. In 1851 the book had reached its 19th edition in England, and in America its success was perhaps greater. Since that time, however, its popularity has declined with almost equal rapidity; judgments on its merits are now as severe as they were formerly favourable, and the name of Brown may be said to be a dead letter in the annals of philosophy. It is interesting to inquire how far this extravagant laudation and neglect are justifiable; and it is of importance to know exactly what were Brown's contributions to mental science, and how far his system is consistent and true.

Some part of Brown's popularity is no doubt to be accounted for from the fact that he was the leader of a revolt against the established system of philosophical thought in Scotland. It had come to be looked upon as established that in the common sense philosophy of Reid alone were metaphysical truth and soundness to be found. Brown not only showed that in many points of detail the earlier Scottish psychology was in fault, above all in their crucial doctrine of perception, but changed the whole aspect of the science by treating it from a thoroughly new and original standpoint. Still more of his fame was due to the lively impression made by his brilliant rhetorical powers. It was a novelty to find the most subtle analysis expounded in the most richly poetical language. Philosophical diction had been dry enough in Reid, and though Dugald Stewart was a master of literary exposition, his eloquence was of a chaste and elegant kind. Brown's, on the other hand, is florid and ornamental to excess, and one soon wearies of the copious quotations from poets like Akenside, Beattie, or Young. Yet the style had, and still has, a certain fascination. But in addition to these extraneous causes, one cannot help acknowledging as the main reason for Brown's quick accession to fame, his undeniable acuteness and originality. His mind was extraordinarily quick and active; there is not one of his lectures which does not contain either some addition to the older doctrine, or some new and striking application of it. What a mind of such fertility and subtility might have achieved had the thinker been spared a little longer, it would be hard to say. But it must not be forgotten in estimating his merits, that we possess only part of his system, and that he had not brought his psychology to bear upon the deeper problems of metaphysics.

Of positive contributions made by him to mental science, the following are perhaps the most important:—(1.) General conception of the object and method of psychology. According to him mental phenomena are to be treated by the recognized methods of physical science. Complex mental facts are to be resolved into their simple elements; and sequences of such facts are to be analyzed so as to bring out the general laws of their connection. Analysis is thus the one instrument to be employed. (2.) View of mental processes and rejection of the ordinary doctrine of faculties. Just as physical science has to analyze and trace the connections of the various phenomena or modes of appearance of matter, without ever reaching the essence which lies behind them, so psychology treats all mental facts as *states* or *modes* or *modifications* of the mind. Perceptions, abstractions, *emotions*, or desires are simply the mind in the several states of perceiving, abstracting, feeling, or desiring. The so-called faculties are nothing but the various modes in which mental activity manifests itself. Consciousness is not to be distinguished from the several mental states. Mental modifications may be classified according to what gives rise to them; they spring up either after some internal cause, or after some other mental mode. In the first case they may be called external states, in the second, internal. The internal may be again divided into intellectual and emotional. (3.) Analysis of touch into touch proper and the muscular sense. This is perhaps the most valuable of Brown's contributions. There are no doubt anticipations of the division, particularly in De Tracy, whom Brown had studied, but his originality is, we think, beyond question. The analysis has since been carried out much more perfectly than by Brown. (4.) Theory of extension. Brown was one of the first to attempt the resolution of our knowledge of extension into a series of muscular feelings, successive in time. His analysis is exceedingly acute, though in many points it must now be looked upon as erroneous. (5.) Doctrine of perception. According to him, all that we *know* of the external world consists of the feelings of resistance, outness, and extension, which are combined into one complex state; but our intuitive belief in the causal principle compels us to postulate a real existence as lying behind and giving rise to these feelings. (6.) Prominence given to the doctrine of suggestion or association. All internal intellectual states may be reduced to simple suggestions, *i.e.*, where one state arises in consequence of another, and to relative suggestion, where the relation between two states gives rise to a third state. Brown analyzes with great skill the powers of suggestion or association, and illustrates very fully the primary and secondary states. Under the head of relative suggestion, he discusses at great length the perception of resemblance or similarity, and draws out an elaborate theory of generalization, intended to supplement the defective view of the Nominalist and to reduce to its proper sphere the supposed abstract idea of the Conceptualist. The analysis was highly popular in its time, but has little of real novelty in it. (7.) Ethical doctrine. To this Brown added little; indeed, the weakest part of his psychology is that bearing upon the will, which he identifies with desire. With regard to conscience, he postulates the existence of a primitive susceptibility to moral emotion; *i.e.*, a certain ethical feeling is infallibly excited by those actions of agents which are right or wrong.

On the whole, it will be seen from this brief statement of what was new in Brown's philosophy, that it occupies an intermediate place between the earlier Scottish school and the later analytical or associational psychology. To the latter Brown really belonged, but he had preserved certain doctrines of the older school which were out of harmony with his fundamental view. He still retained a small quantum of intuitive beliefs, and did not appear to see that the very existence of these could not be explained by his theory of mental action. This intermediate or wavering position accounts for the comparative neglect into which his works have now fallen. They did much to excite thinking, and advanced many problems by more than one step, but they did not furnish a coherent system, and the doctrines which were then new have since been worked out with greater consistency and clearness.

For a severe criticism of Brown, see Sir W. Hamilton's *Discussions* and *Lectures on Metaphysics*; and for a high estimate of his merits, see J. S. Mill's *Examination of Hamilton*. The only German writer who seems to have known anything of Brown is Beneke, who found in him anticipations of some of his own doctrines. See *Die Neue Psychologie*, pp. 320–330. (R. AD.)

BROWN, Ulysses Maximilian, a celebrated general in the imperial armies, son of Ulysses, Baron Brown and Camus, a colonel of cuirassiers, was descended of an ancient Irish family, and was born at Basel in 1705. After studying at Limerick, Rome, and Prague he entered the army, becoming in 1723 captain in the regiment of his uncle, Count George Brown, and in 1725 lieutenant-colonel. He served with great distinction in Corsica and Italy, and in 1739 was made field-marshal-lieutenant, and counsellor in the aulic council of war. After the death of the Emperor Charles VI. he became one of the foremost generals in the army of the Empress-Queen Maria Theresa, and gained a high reputation for military skill. On the outbreak of the Seven Years' War, Count Brown, with the rank of field-marshal, assembled his army in Bohemia, and repulsed the Prussians at the battle of Lowositz. He was mortally wounded at the great battle of Prague, and was carried into the town, where he expired on the 20th June 1757.

BROWN, William Laurence, born at Utrecht, January 7, 1755, was the son of the Rev. William Brown, minister of the English church in that city. The father, having been appointed professor of ecclesiastical history at St Andrews, returned to Scotland in 1757, and his son was in due time sent to the grammar school of that city. At the age of twelve he entered the university, and after passing through the classes of divinity, removed in 1774 to the university of Utrecht, where he combined with the study of theology that of the civil law. In 1777 he was appointed to the charge of the English church in Utrecht, which had been previously held by his father and uncle. About 1788 he was appointed to the professorship of moral philosophy and ecclesiastical history in the university of Utrecht, to which was soon added the professorship of the law of nature. The war which followed the French Revolution finally drove Dr Brown from the place of his nativity. In January 1795 he made his escape to England. In London he experienced such a reception as was due to his literary talents and moral worth; and in 1795 the magistrates of Aberdeen appointed him to the chair of divinity on the retirement of Dr George Campbell, and soon after he

was made principal of Marischal College. In the year 1800 he was appointed chaplain in ordinary to the king, and in 1804 dean of the chapel royal, and of the Order of the Thistle. He died on the 11th of May 1830, in the seventy-sixth year of his age.

His most widely known works were an *Essay on the Natural Equality of Men*, 1793, which gained the Teyler Society's prize; a treatise *On the Existence of the Supreme Creator*, 1816, to which was awarded the first Burnet prize of £1250; and *A Comparative View of Christianity, and of the other Forms of Religion which have existed and still exist in the World, particularly with regard to their Moral Tendency*, 1826.

BROWNE, Charles Farrar, an American humorous writer, best known under his *nom de plume* of Artemus Ward, was born at Waterford, Maine, in 1834. He began life as a compositor and occasional contributor to the daily and weekly journals. In 1858 he published in the Cleveland *Plaindealer* the first of the "Artemus Ward" series, which in a collected form attained great popularity both in America and England. In 1860 he became editor of *Vanity Fair*, a humorous New York weekly, which proved a failure. About the same time he began to appear as a lecturer, and by his droll and eccentric humour attracted large audiences. In 1866 he visited England, where he became exceedingly popular both as a lecturer and as a contributor to *Punch*. In the spring of the following year his health gave way, and he died of consumption at Southampton on the 6th March 1867. For a critical estimate of his works see the article American Literature, vol. i. p. 728.

BROWNE, Isaac Hawkins, an English poet, was born in 1705 at Burton-upon-Trent, of which place his father was minister. He received his grammatical instruction first at Lichfield, and then at Westminster, whence, at sixteen years of age, he was removed to Trinity College, Cambridge, of which his father had been fellow. After taking his master's degree he removed to Lincoln's Inn, where he applied closely to the study of the law. Not long after the commencement of his professional studies, he wrote a poem on *Design and Beauty*, which he addressed to his friend Highmore the painter. Here also he wrote his most popular poem, entitled *The Pipe of Tobacco*, in which he gave imitations of Cibber, Ambrose Philips, Thomson, Young, Pope, and Swift, who were then all living. In 1744 he married the daughter of Dr Trimnell, archdeacon of Leicester. He was elected in 1744 and again in 1748 to serve in parliament for the borough of Wenlock in Shropshire, near which place he possessed a considerable estate, left to him by his maternal grandfather. In 1754 he published his poem *De Animæ Immortalitate*, in which, besides a judicious choice of matter and arrangement, there is thought to be a happy imitation of Lucretius and Virgil. The wide popularity of this poem produced several English translations of it, the best of which is given by Soame Jenyns, in his *Miscellanies*. The author intended to have added a third book, but of this he had left only a fragment. He died, after a lingering illness, in 1760. In 1768 his son published an elegant edition of his poems, in large octavo.

BROWNE, James, LL.D., man of letters, for a number of years sub-editor of the seventh edition of the *Encyclopædia Britannica*, was born at Coupar-Angus in 1793. He was educated at Edinburgh and afterwards removed to St Andrews, where he studied for the church. He wrote *The History of Edinburgh* for Ewbank's Picturesque Views of that city, 2 vols., 1823–25. In 1826 he became a member of the Faculty of Advocates, and obtained the degree of LL.D. from King's College, Aberdeen; and in this same year he published a *Critical Examination of Macculloch's Work on the Highlands and Islands of Scotland*. In 1827 he published at Paris his *Aperçu sur les Hieroglyphes d'Egypte*; and in the following year there appeared his *Vindication of the Scottish Bar from the Attacks of Mr Brougham*. He was now appointed editor of the *Caledonian Mercury*; and two years later he became sub-editor of the *Encyclopædia Britannica*, to which he contributed a large number of valuable articles. He also published in 1838 a *History of the Highlands and Highland Clans*, 4 vols. 8vo, of which various editions have since appeared. His mental activity was remarkable, and frequently urged him to exertions beyond his strength. He died in 1841, from a stroke of apoplexy, brought on by his unremitting labours.

BROWNE, Peter, bishop of Cork and Ross, an able writer on theology, was born in Ireland some time after the Restoration. He entered Trinity College, Dublin, in 1682, and after ten years' residence obtained a fellowship. In 1699 he was made provost of the College, and in the same year published his *Letter in answer to a Book entitled "Christianity not Mysterious,"* which was recognized as the ablest reply yet written to Toland. It expounds in germ the whole of his later theory of analogy. In 1710 he was made bishop of Cork and Ross, which post he held till his death in 1735. In 1713 he had become somewhat notorious from his violent onslaught on the fashion of drinking healths, a polemic which he carried on in several pamphlets. His two most important works are the *Procedure and Limits of the Human Understanding*, 1728, an able though sometimes captious critique of Locke's essay, and *Things Divine and Supernatural conceived by Analogy with Things Natural and Human*, more briefly referred to as the *Divine Analogy*, 1733. The doctrine of analogy was intended as a reply to the deistical conclusions that had been drawn from Locke's theory of knowledge. Browne holds that not only God's essence, but his attributes are inexpressible by our ideas, and can only be conceived analogically. This view was vigorously assailed by Berkeley in his *Alciphron* (Dialogue IV.), and great part of the *Divine Analogy* is occupied with a defence against that criticism. The bishop emphasizes the distinction between metaphor and analogy; though the conceived attributes are not thought as they are in themselves, yet there is a reality corresponding in some way to our ideas of them. The doctrine of analogy is interesting, and has an interesting history in English theology. Its most logical expression may be found in the *Bampton Lectures* of the late Dean Mansel.

BROWNE, Sir Thomas, a distinguished English writer, was born in London on the 19th October, 1605. He was educated at Winchester School, and afterwards at Broadgate Hall (Pembroke College), Oxford, where he graduated B.A. in January 1626. He took the further degree of M.A. in 1629, studied medicine, and practised for some time in Oxfordshire. Between 1630 and 1633 he left England, travelled through Ireland, France, and Italy, and on his way home received the degree of M.D. at the university of Leyden. He returned to London in 1634, and two years later, after a short residence in Yorkshire, settled in practice at Norwich. In 1642 a copy of his *Religio Medici* was printed from one of his MSS. without his knowledge, and he was compelled to put forth a correct edition of the work, which appears to have been composed as early as 1634. Its success was very great, and the author at once became celebrated as a man of letters. In 1646 appeared his *Pseudodoxia Epidemica*, or *Enquiries into Vulgar and Common Errors*, which added to his fame. In 1658, on the occasion of the discovery of some ancient urns in Norfolk, he wrote his *Hydriotaphia* or *Urnburial*, to which was appended *The Garden of Cyrus*. These four works were all that he published, though several tracts,

notably the *Christian Morals* and *Antiquities of Norwich*, were prepared for publication, and appeared after his death. In 1671 he received the honour of knighthood from Charles II. on his visit to Norwich; and in 1682 he died on his seventy-seventh birthday.

Browne is in every way a remarkable and peculiar writer. His writings are among the few specimens of purely literary work produced during a period of great political excitement and discord. England was passing through its greatest convulsion; events of mighty moment were being transacted round him, and he remained placidly indifferent. While the grandest minds of his country were busied with the important affairs of state, he was revising his *Religio Medici*, and his book was published in the very year in which the civil war broke out. While England was torn with civil discord, and the liberty of her children was being bought with their blood, Browne serenely pursued his studies at Norwich, to all appearance as indifferent to contemporary events as if he had belonged to another planet. Just when there came a lull in the conflict, when the royal power was broken, and the air was filled with doubts, anxieties, and negotiations, Browne published his *Pseudodoxia Epidemica*. The death of the king, the expulsion of the parliament, the establishment of the protectorate, passed by him like a breath which he heeded not. But the unearthing of some sepulchral urns at once roused his attention, and furnished occasion for a train of most magnificent and majestic reflections on the short space of human life, on the signs and symbols of mortality. A mind like this is a psychological curiosity, and its peculiarities are faithfully reflected in the form and matter of his works. In some respects, of course, he resembles his contemporaries; in his, as in all other writings of the 17th century, there is a plentiful display of erudition, copious citation of authorities, and lavish quotation from older writers. Some part also of the peculiarity of his style may be ascribed to the general tendency of the language at that period. It was a time of unusual richness of diction; great writers did not hesitate to coin words and phrases as occasion required them, and ample raw material was supplied by the great mass of literature, which had been but recently opened up, and which was then being assimilated. But Browne stands apart from his contemporaries by reason of the peculiar and unique cast of his mind. Deeply speculative, imbued with the Platonic mysticism which taught him to look upon this world as only the image, the shadow of an invisible system, he regarded the whole of experience but as food for contemplation. Nothing is too great or too small, too far removed or too near at hand for him; all finds a place in the universe of being, which he seems to regard almost from the position of an outsider. His general mood may be characterized as the metaphysical; not that he speculated systematically on the problems of existence, but because he dwells repeatedly, and with evident delight, upon what transcends the little sphere of our life, and, like Shakespeare, is fond of meditating on the outward and visible signs of mortality, and on what lies beyond the grave.

Of Browne, however, as of our greatest writers, it is true that the style is the man. The form of his thought is as peculiar and remarkable as the matter; the two, indeed, react upon one another. It is a style altogether unique,—rich, with a lavish use of metaphor and analogy—majestic and swelling, and with a fine antique flavour about it. Much of its quaintness, no doubt, depends on the excessive employment of Latinized words, great part of which have never succeeded in making their way into the standard language; but the peculiarities of the vocabulary do not entirely exhaust those of the style. Of his four masterpieces the *Religio Medici* is that in which we are most in contact with the writer himself. The book was a puzzle to contemporaries, and is still hard to understand. It is the confession of faith of a mind keen and sceptical in some aspects, but on the whole deeply imbued with the sense of the mysteriousness of true religion, and willing to yield itself up without reserve to the requirements of faith. "I love," he says, "to lose myself in a mystery, to pursue my reason to an *O, Altitudo!*" The *Vulgar Errors* is a wonderful storehouse of out-of-the-way facts and scraps of erudition, exhibiting a singular mixture of credulity and shrewdness. The style is more direct and simple than in the other works. The *Garden of Cyrus* is a continued illustration of one quaint conceit. The whole universe is ransacked for examples of the *Quincunx*, and he discovers, as Coleridge says, "quincunxes in heaven above, quincunxes in earth below, quincunxes in the mind of man, quincunxes in tones, in optic nerves, in roots of trees, in leaves, in everything!" But the whole strength of his genius and the wonderful charm of his style are to be sought in the *Urnburial*, the concluding chapter of which, for richness of imagery and majestic pomp of diction, can hardly be paralleled in the English language. For anything at all resembling it we must turn to the finest passages of Jeremy Taylor or of Milton's prose writings.

The best edition of Sir T. Browne is that by Simon Wilkin, 4 vols., 1836,—3 vols. (Bohn), 1851, where full biographical and bibliographical information will be found. Prefixed to it is Johnson's celebrated *Life*.

BROWNE, William, an English poet, descended of a good family, was born at Tavistock in Devonshire, in 1590. Having passed through the grammar school of his native place, he was sent to Exeter College, Oxford, and became tutor to Robert Dormer, afterwards earl of Carnarvon. After having received in 1624 the honorary degree of M.A., he was taken into the family of William, earl of Pembroke, and improved his fortune so much that he is said to have purchased an estate. Nothing seems to be known of his after life, and no date has ever been given for his death. All his work was done in his youth, the first part of *Britannia's Pastorals* having been published in 1613, *The Shepherd's Pipe* in 1614, and the second part of the *Pastorals* in 1616. He belongs to the school of Spenser, and his merits may be summed up briefly as extreme sweetness of verse, idyllic nature-painting, and richness of descriptive faculty. The *Pastorals* are about the finest specimens we have in earlier literature of luxuriant sensuous description of ordinary country life. They were highly popular in their time. (See Wood, *Athen. Oxon.*)

BROWNE, William George, an eminent traveller, was born at Great-Tower-Hill, London, July 25, 1768. At seventeen he was sent to Oriel College, Oxford. Having had a moderate competence left him by his father, on leaving the university he applied himself entirely to literary pursuits. But the fame of Bruce's travels, and of the first discoveries made by the African Association, determined him to become an explorer of Central Africa. Accordingly, he left England at the close of 1791 and arrived at Alexandria in January 1792. He spent a few months in visiting Siwah, the supposed site of the temple of Jupiter Ammon, and employed the remainder of the year in examining the whole of Egypt. In the spring of 1793 he visited Suez and Sinai, and in May set out for Darfûr. This was his most important journey, in which he acquired a great variety of original information. He endured much hardship, and was unable to effect his purpose of returning by Abyssinia. He did not reach Egypt till 1796; after this he spent a year in Syria, and did not arrive in London till September 1798. In 1800 he published his travels in Africa, Egypt, and Syria, from the year 1792 to 1798, in one volume 4to. The work was highly esteemed, and is classed by Major Rennell

among the first performances of the kind; but, from the abruptness and dryness of the style, it never became very popular. In 1800 Browne again left England, and spent three years in visiting Greece, some parts of Asia Minor, and Sicily. In 1812 he set out on a more extensive journey, proposing to penetrate to Samarkand, and survey the most interesting regions of Central Asia. He spent the winter in Smyrna, and in the spring of 1813 proceeded through Asia Minor and Armenia, made a short stay at Erzeroum, and arrived on the 1st of June at Tabriz, where he met Sir Gore Ouseley. About the end of the summer of 1813 he left Tabriz for Teheran, intending to proceed thence into Tartary; but unhappily he never reached that destination. Near the banks of the Kizil-Ouzen his party were attacked by banditti, and, according to the report of the survivors, Browne was plundered and murdered. Suspicion attached to his companions, and even to the Persian Government, but nothing occurred to confirm these surmises. Some bones, believed to be his, were afterwards found and interred near the grave of Thevenot, the celebrated French traveller. His volume of travels in Africa has already been mentioned. Robert Walpole published in the second volume of his Memoirs relating to European and Asiatic Turkey (4to, 1820), from papers left by Browne, the account of his journey in 1802 through Asia Minor to Antioch and Cyprus; also "Remarks written at Constantinople."

BROWNING, Elizabeth Barrett, the most distinguished poet of her sex that England has produced, was born in London in the year 1809. She was the daughter of Mr Barrett, an English country gentleman. From a very early age, almost before the years of childhood had passed, she exhibited a remarkable preference for the arts, but especially that of the poetic. Previous to attaining her fifteenth year she had written verse upon which was the stamp of true genius—poems eminently worthy of preservation Whatever she wrote, however, was sacred to all eyes save those of her father, to whom she refers in the first collected edition of her poems as "my public and my critic." Her physical constitution was most fragile and delicate, but nature seemed to have supplemented her deficiency in this respect by bestowing upon her an unusually sensitive mental and spiritual organization. One who knew her intimately, Miss Mitford, has described her as a "slight delicate figure, with a shower of dark curls falling on each side of a most expressive face, large tender eyes, richly fringed by dark eye-lashes, and a smile like a sunbeam." All descriptions of Miss Barrett concur in this, that she possessed a grace and a delicacy which defied representation by the artist. Her studies were early directed to the poets of antiquity, and, under the guidance of her blind tutor, Boyd, whose name she always warmly cherished, she mastered the rich treasures of Æschylus The sublime Grecian possessed for her a charm which was only equalled by the fascination held over her wondering spirit by our own Shakespeare. Her knowledge of Greek literature was most profound; she was intimately familiar with all the Attic writers in tragedy and comedy. Yet this did not prevent her from drinking at the wells of English undefiled. Her correspondence with eminent contemporaries of both sexes proves her to have been thoroughly acquainted with English literature in its progress from Chaucer downwards. The circumstances of her own life, and her lack of robust health, conspired to make her seek, even more than she might have otherwise done, the communion of the great departed in arts and letters. Not being able to pass from place to place without fatigue and danger, the solitude she was compelled to maintain probably threw her still more ardently into those pursuits which, while dear to the mind, were probably injurious to the body. Most frail from her birth, as we have already seen, it was her misfortune further to have her existence endangered in 1837 by the bursting of a blood-vessel in the lungs. By the exercise of extreme care her life was preserved, but the incident was succeeded by a long period of weakness and suffering. Some two years after this first severe shock to her system, and before she had quite recovered from its effects, she was again assailed by misfortune, experiencing the keenest anguish on witnessing the death of her favourite brother, who was drowned at Torquay. As might have been expected from one of her clinging and affectionate disposition, a long period of danger followed this catastrophe, and when at length she was able to be removed to her father's house, it was only to become an invalid, with the prospect of a life couch-ridden to its close. This period of seclusion lasted for seven long years; and the interval was employed by Miss Barrett in eagerly devouring all the books which could be brought within her reach. At this time also she was sedulously cultivating the art that was afterwards to ensure for her immortality. When she was in her thirty-seventh year, that is, in 1846, she was married to Mr Browning, and the union was singularly felicitous. More cannot be said, as the author of *The Ring and the Book* still lives. Mr Browning bore his wife to Italy, and for some years the sunny skies of the south were instrumental in giving to Mrs Barrett Browning that health which had so long forsaken her in her native land. The villa of the Brownings in Florence was the resort of many noble spirits, eminent either for patriotism or in the arts. Mrs Browning died at Florence in the year 1861, after testifying in many ways her singular devotion to the country of her adoption.

The poetry of this writer is distinguished for its emotional spirit; had her imagination equalled her capacity for feeling she might have taken rank with the highest of our poets. Sensibility and intuition, those endowments of supreme importance to writers of genius, whose greatness is to grow in proportion to their understanding and interpretation of human life, were in her united in a degree seldom witnessed. The aspirations she indulged, and the character she doubtless wished to be impressed upon her own works, were well set forth when she observed on one occasion, "we want the touch of Christ's hand upon our literature as it touched other dead things; we want the sense of the saturation of Christ's blood upon the souls of our poets, that it may cry through them in answer to the ceaseless wail of the sphinx of our humanity, expounding agony into renovation. Something of this has been perceived in art when its glory was at the fullest. Something of a yearning after this may be seen among the Greek Christian poets, something which would have been much with a stronger faculty." Imbued fully with this idea of the sacredness of poetry, Mrs Browning went to the deepest fount of all inspiration—the human heart—and endeavoured to read clearly its intimate relations with God. A peculiar tenderness breathes through her writings, whether of the humblest or the most ambitious description. Almost her first work bore upon it the traces of her Greek studies, being an excellent translation of the *Prometheus*. Another very early production, *The Drama of Exile*, is unquestionably marked by great sublimity of thought, though the conception may lack the mighty outlines of the majestic Milton. Eloquent and sustained, however, the poem made manifest a pure and original writer. Mrs Browning's genius had two sides—the lyric and the dramatic. Her lyrical capabilities were of the highest order: she was greater probably in this particular than either Campbell or Tennyson, though on several occasions Campbell touched the loftiest point such a writer can attain. The heart, which has always given our lyric poets their greatest power, was the strength of Mrs Browning; her song was a living

voice, eloquent with passion. In one of her lyrics she uttered her conclusion upon the human mystery, "knowledge by suffering entereth, and life is perfected by death." The spirituality of her "Vision of Poets" is a noticeable quality, and it is in a loftier strain than that of "The Two Voices," though cast in the same mould. Wandering amongst the minor poems of Mrs Browning, such for instance as "The Romaunt of Margret," "Isobel's Child," "Bertha in the Lane," and "the Swan's Nest among the Reeds," is like standing in the forest alone, with the wailing wind and the flying rain as the only assurances of an existence sublimer than our own. Yet she has thereby reached the profoundest depths of the human heart. But even when most depressed she does not lose faith—confidence in the triumph of the good and the right. To her it was not always necessary to understand the wrong which she beheld; she saw it and hated it, and she has helped men by her writings to do something towards making an end of it. "The Cry of the Children" is a striking illustration of her keen feeling and eloquent power as a philanthropist. She felt for all who are in any way crushed or bruised by the pressure of society, and of social distinctions, or of social misfortunes. Her poetry bears the impress of tender and profound sympathy with human suffering in every form.

The range of this author's powers was wide, as may be gathered by a comparison between such poems as "A Child's Thought of God" and "Casa Guidi Windows." In the latter she attained her ripest growth and greatest intellectual strength. The poem is as sustained as anything which she ever wrote, and more perfect than the remaining lengthy poems. The "Casa Guidi Windows" had the advantage of a direct and powerful inspiration. From her windows at Florence Mrs Browning looked out upon the Italian people struggling for freedom, and her enthusiasm was enkindled. Her utterances were therefore in accordance with the fulness of her heart, lavish and unrestrained. The extraordinary wealth and strength of imagery which the poem contains must have been noticed by every reader, and it includes doubtless much of her finest writing. In the inditing of the sonnet, always conceded to be a most difficult task, Mrs Browning was very successful. She is the equal of Wordsworth in this respect, and her "Sonnets from the Portuguese" (but thinly disguised, and giving really the history of her own feelings) are a compact and remarkable series of verses. They present us with a complete study of a human heart as it is affected by the passion of love. First, there is the soul expecting death, when suddenly life is revivified by love; then the grave, which had seemed inevitable, is put behind the soul; and finally comes the sequel, the marriage of those whose history has been traced in the Sonnets. The unity and psychological interest of this series of poems are their most prominent features.

Mrs Browning's fame chiefly rests upon *Aurora Leigh*, except with diligent and reverent students of her other works. The longest poem, nevertheless, which came from her hand is the one, to quote her own words, into which her "highest convictions upon life and art have entered." Yet it has had the result of causing a wide diversity of opinion upon its merits. Extravagant encomiums or unjust aspersions are generally awarded to it. For a poem of such magnitude unity is essential, and this we find to be lacking. It has not the one purpose—never ignored and never forgotten—which runs through *In Memoriam*. One of its great charms, however, viz., its intense subjectivity, will prevent *Aurora Leigh* from falling into desuetude. The writer unfolds with great beauty of expression the truth that that is real art which assists in any degree to lead back the soul to contemplate God, the supreme artist of the universe. But notwithstanding its philosophy, as a solution for many of the problems of our social existence, the poem must be pronounced a failure. It is charged with passages of lofty poetry, though occasionally it falls into mediocrity. It is to be regarded rather as an autobiography (which indeed it claims to be) than as a poem characterized by fine conception or perfect execution. The position of Mrs Browning as a poet is now yielded. Her genius was perhaps as great as that of any poet of our generation, but circumstances retarded its highest possible development. In certain intellectual qualities she was inferior to Tennyson and the author of *Sordello*, but in others she was their superior. Be her exact niche, however, what it may, she occupies a favoured place in English literature, and is undoubtedly one of the few leading poets of the 19th century. Her poetry is that which refines, chastens, and elevates. Much of it is imperishable, and although she did not reach the height of the few mighty singers of all time, she has shown us the possibility of the highest forms of the poetic art being within the scope of woman's genius. (G. B. S.)

BROWNISTS, a religious sect, which sprang up towards the close of the 16th century, and which received its name from the first promulgator of the doctrines, Robert Brown. Their numbers increased rapidly, and Sir Walter Raleigh, in a speech in 1592, estimated them at no less than twenty thousand. The harsh measures that were taken against them, and the disgust generally excited by the tone of their attacks upon the Established church, for a time stamped out the sect in England. But the remnant found a refuge in Holland, and the church established there between 1593 and 1608 included many eminent men, such as Ainsworth, Johnson, Smyth, Jacob, Clifton, and Robinson, and gradually increasd in numbers. Soon, however, differences of opinion began to arise; some, with Smyth, carried out the principles of Brownism to their full extent, and became absolute Separatists; others, with Robinson, adopted a milder form of opposition to the church, which ultimately resulted in Independency. The stronger stream of tendency set in towards this latter form of doctrine, and the Brownists soon faded out of view and gave place to the Independents. The occasion of the Brownists' separation was not any fault they found with the faith, but only with the discipline and form of government of the other churches in England. They charged corruption equally on the Episcopal form and on that of the Presbyterians by consistories, classes, and synods; nor would they join with any other Reformed church, because they were not assured of the sanctity and regeneration of the members who composed it, on account of the toleration of sinners, with whom they maintained it an impiety to communicate. They condemned the solemn celebration of marriages in the church, maintaining that, as matrimony was a political contract, the confirmation of it ought to come from the civil magistrate. They would not administer baptism to the children of such as were not members of the church, or of such as did not take sufficient care of their children already baptized. They rejected all forms of prayer, and held that the Lord's Prayer was not to be recited as a prayer, having been given only for a rule or model whereon all our prayers are to be formed. The form of church government which they established was democratical. When a church was to be gathered, such as desired to be members of it made a confession and signed a covenant, by which they obliged themselves to walk together in the order of the gospel. The whole power of admitting and excluding members, with the decision of all controversies, was lodged in the brotherhood. The church officers were chosen from among themselves, for preaching the word and taking care of the poor, and were separated to their several offices by fasting, prayer, and imposition of hands by some of the brethren. But they did not erect the priesthood into a

distinct order. As the vote of the brotherhood made a man a minister, and gave him authority to preach the word and administer the sacraments among them, so the same power could discharge him from his office, and reduce him to the condition of a mere layman again. And as they maintained that the bounds of a church were defined by the number of those who could meet together in one place, and join in one communion, so the power of these officers was confined within the same limits. The minister or pastor of one church could not administer the Lord's Supper to another, nor baptize the children of any but those of his own society. Any lay brother was allowed the liberty of prophesying, or of giving a word of exhortation to the people; and it was usual for some of them, after sermon, to ask questions, and reason upon the doctrines which had been preached. In a word, every church on the Brownists' model is a body corporate, having full power to do everything which the good of the society requires, without being accountable to any presbytery, synod, assembly, convocation, or other jurisdiction whatever. (See Fuller, Neal, Fletcher, Hanbury, and Masson, *Life of Milton*, vol. ii. pp. 534, *seq.*)

BRUCE, James, a celebrated African traveller, was born at Kinnaird House, Stirlingshire, on the 14th December 1730. He was educated at Harrow, and at first turned his attention to the bar. After his marriage, however, he entered into business as a wine-merchant, but soon gave up any active share in the concern. His wife had died within a year of their marriage, and Bruce, after acquiring a knowledge of the Spanish and Portuguese languages, travelled on the Continent for some time, returning to England in 1758. He then made a proposal to the English Government that they should make a descent upon Spain at Ferrol, assuring them from his own observation that the coast was without defence at that place. His suggestions were not adopted; but Lord Halifax, to whom he had been introduced, and who had consulted him about the exploration of the Nile, appointed him soon afterwards to the consulship at Algiers. He arrived at that place in March 1762, and after spending a year in the study of Arabic and other Oriental languages, set out through Tunis, Tripoli, and the North of Africa. He then visited Rhodes and Cyprus, and explored great part of Syria and Palestine, making very careful drawings of Palmyra and Baalbec. These drawings were afterwards presented to the king and placed in the royal library at Kew. It was not till June 1768 that Bruce arrived at Alexandria, and prepared to start on his great exploring expedition. From Cairo he sailed up the river as far as Syene; he then struck across the desert to Kosseir, and reached Jidda in May 1769. He remained for some time in Arabia, set sail from Loheia on the 3d September, and on the 19th arrived at Massowah. There he was detained for some time; but at last, on the 15th February 1770, he made his way to Gondar, the capital of Abyssinia. He gained great favour with the Abyssinian king, and remained with him till October, when he set off up the Bahr-el-Azrek, which he looked upon as the main branch of the Nile. On the 14th November he reached the sources of the Bahr-el-Azrek, and proudly imagined himself to have solved the great geographical problem. Slowly and with great difficulty he made his way back through the deserts of Nubia. On the 29th November 1772 he reached Assouan on the Nile. Thence he returned into the heart of the desert to recover his baggage, which had been abandoned in consequence of the death of all his camels. In January 1773 he arrived at Cairo. On his way home to England he spent some time at Paris, where he was warmly received by Buffon and other eminent men of science. The celebrated *Travels* did not appear till 1790, when they were published in five large quarto volumes, profusely illustrated. The work was received with favour on account of its freshness and interest, but with almost universal incredulity. The *Travels* were looked upon as veritable travellers' tales, not entitled to any respect as authentic narrative. Succeeding investigations, however, have thoroughly dispelled these suspicions, and reinstated the book in popular estimation. Bruce died in 1794, in consequence of a fall down the staircase of his own house. A second edition of his work, on which he was engaged at the time of his death, was published in 1804.

BRUCE, Michael, a minor Scottish poet, was born at Kinnesswood, Kinross-shire, 27th March 1746, and was the son of a weaver. He was early sent to school, but his attendance was often interrupted. He had frequently to herd cattle on the hills in summer, and this early companionship with nature greatly influenced his mind and awoke the latent poetry of his genius. Delicate from birth he grew up contemplative, devotional, and humorous, the pet of his family and his friends. His parents gave him an education superior to their position; at fifteen, when his school education was completed, his father was enabled to send Michael to Edinburgh University, which he attended during the four winter sessions 1762–5. In 1765 he got employment as a teacher during the summer months at Gairney Bridge, receiving about £11 a year in fees. He became a divinity student of a dissenting Scotttish sect known as the Burghers, and in the first summer of his divinity course accepted the charge of a new school at Forrest Mill, where "he lead a melancholy kind of life." Poverty, disease, and want of companions depressed his spirits, but in that solitariness he wrote "Lochleven," a poem inspired by the memories of his childhood. In consequence of advanced consumption he had to give up the school, and returned to his father's house, where he wrote his last and finest poem, "Elegy written in Spring," and died on 5th July 1767, aged twenty-one years and three months. As a poet his reputation has been increased, first, through sympathy for his early death, and secondly, from the alleged theft by Logan of several of his poems. The Rev. John Logan, minister of Leith, a fellow-student of Bruce, edited in 1770 the *Poems on several occasions, by Michael Bruce*, in which the "Ode to the Cuckoo" appeared. In the preface he stated, "To make up a miscellany, some poems written by different authors are inserted." In a collection of his own poems in 1781, Logan printed the "Ode to the Cuckoo" as his own; of this the friends of Bruce were aware, but did not challenge it. Dr M'Kelvie, in his *Life and Works of Bruce* (1837), was the first to claim for him the authorship of the Ode, and of other verses of which Logan had hitherto been the reputed author. This claim rests on the oral tradition of his birthplace and the evidence of a few of his friends; it was made nearly fifty years after Logan's death, and no explanation can be given of this great lapse of time. Of direct testimony there is none, and irrelevant matter is brought in affecting Logan's character, while Logan's authorship rests on such ground as publication under his own name, and his reputation as author during his lifetime. By reiteration of Bruce's claims in many forms popular opinion has been gained for him, though Isaac D'Israeli, Thomas Campbell, Robert Chambers, and David Laing have strenuously supported Logan. The dispute cannot now, perhaps, be satisfactorily settled, owing to the conflict of evidence and lapse of time; but on the whole it may be doubted whether M'Kelvie has proved his case. All Bruce's poems breathe the thoughts of a shepherd lad, as Bloomfield's retained the fresh observations of a farmer's boy. With two exceptions they are immature and lack strength; his imagery is in great measure borrowed; his rhymes evince a paucity of poetical skill. His early attempts are weak imitations of Milton, Thomson, and Young, his

favourite poets. His "Lochleven" and "Elegy written in Spring" are alone worthy of preservation, and both were composed in his last year. The former abounds in happy word-painting and moral reflections. The tale of Levina, which forms about the half of the poem, and is by far the prettiest flower in the bouquet, bears distinct marks of the same hand that wrote "Runnimede." The "Elegy" is most affecting, when read in the knowledge of the circumstance of its having been written by a dying youth of twenty-one:—

> "Led by pale ghosts I enter death's dark gate,
> And bid the realms of light and life adieu."

It is a death song, remarkable for exquisite beauty and chaste simplicity. Bruce is not to be compared with another young Scottish poet, Robert Nicoll. His life wanted the fulness and strength, his poems the wide and vivid sympathies of his later compeer.

BRUCE, Robert, king of Scotland. See Scotland.

BRUCHSAL, a town of the Grand Duchy of Baden, in the circle of Carlsruhe, 14 miles from the city of that name, on the Salzbach. From 1056 to 1801 it was the seat of the bishop of Spires, whose magnificent palace is still extant; and it has an old castle of the 12th century (now used as a prison), a town-house, a gymnasium, a hospital, barracks, and a considerable trade in wine. Population in 1872, 9762. The town was originally the seat of an imperial palace, and its name is said to be derived from *bruch* a marsh, and *sala*, royal possession. The Peasants' War first broke out at Bruchsal, which has been several times reduced to ashes in subsequent conflicts. In 1849 it was the scene of an engagement between the Prussian troops and Baden insurgents.

BRUCK, the name of two towns of Austria—

(1.) Bruck on the Mur, the chief town of a circle in the province of Steyermark, situated at the junction of the rivers Mur and Mürz, with a station on the railway from Vienna to Trieste, 25 miles N.W. of Gratz. It contains about 2900 inhabitants, and has a considerable transit trade. The principal building is the palace of the ancient princes of Bruck, which dates from the 14th century.

2. Bruck on the Leytha, the chief town of a circle in Lower Austria, with the castle of the counts of Harrach. It lies on the Vienna and Buda railway, 20 miles S.E. of Vienna. Population, 4203.

BRÜCKENAU, a town and fashionable watering-place of Bavaria, in the circle of Lower Franconia, on the Sinn, 16 miles N.W. of Kissingen. The mineral springs, which are five in number, situated in the pleasant valley of the Sinn, 2 miles from the town, were a favourite resort of Louis I. of Bavaria. Population in 1871, 2825.

BRUCKER, James, theologian, historian, philologer, and biographer, was born at Augsburg on the 22d of January 1696. His father, who was a respectable burgher, destined him for the church; and his own inclinations according with his father's wishes, he was sent at the usual age to pursue his studies in the university of Jena. Here he took the degree of master of arts in 1718; and in the following year he published his *Tentamen Introductionis in Historiam Doctrinæ de Ideis*, in 4to,—a work which he afterwards amplified and completed, and republished under the title of *Historia Philosophica Doctrinæ de Ideis*, at Augsburg in 1723. He returned to his native city in 1720; but here his merit having attracted envy rather than recompense, he was induced to accept of the office of parish minister of Kaufbevern in 1723. In the same year he published a memoir *De Vita et Scriptis Cl. Etringeri*, Augs. 8vo. His reputation having been at length established by these learned works, in 1731 he was elected a member of the Academy of Sciences at Berlin; and soon afterwards he was invited to Augsburg to fill the honourable situation of pastor and senior minister of the church of St Ulric. He published in the same year three dissertations relating to the history of philosophy, under the title of *Otium Vindelicum sive Meletematum Historico-philosophicorum Triga*, Augsburg, 1731, 8vo. Besides several smaller dissertations on biography and literary history, printed at different times, and which he afterwards collected in his *Miscellanea*, he published at Ulm, in 1737, *Neue Zusätze verschiedener Vermehrungen, &c., zu den kurtzen Fragen aus der philosophischen Historie*, 7 vols. 12mo. This work being a history of philosophy in question and answer, contains many details, especially in the department of literary history, which he has chosen to omit in his greater work on the same subject. He was forced by the booksellers, in opposition to his own opinion, to adopt the erotematic method, which at that time had been rendered popular by the writings of Hubner and Rambach.

In 1741, at Leipsic, appeared the first volume of his great work, *Historia Critica Philosophiæ, a mundi incunabulis ad nostrum usque ætatem deducta*. Four other ponderous quartos, completing the first edition of this elaborate history, followed in 1744. Such was the success of this publication, that the first impression, consisting of four thousand copies, was exhausted in twenty-three years, when a new and more perfect edition, the consummation of the labours of half a century devoted to the history of philosophy, was in 1767 given to the world in six volumes quarto. The sixth volume, consisting entirely of supplement and corrections, is applicable to the first as well as to the second edition. Of the merits of this work we shall speak in the sequel.

His attention, however, was not wholly occupied by this stupendous undertaking. The following books would of themselves have been sufficient to exhaust the industry of any ordinary author:—*Pinacotheca Scriptorum nostra ætate literis illustrium*, &c., Augsburg, 1741–55, folio, in five decades. *Ehrentempel der Deutschen Gelehrsamkeit in welchem die Bildnisse gelehrter Männer unter den Deutschen aus dem XV., XVI., und XVII. Jahrhundert aufgestellet, und ihre Geschichte, &c., entworfen sind*, Augsburg, 1747–49, 4to, five decads. *Institutiones Historiæ Philosophicæ*, Leipsic, 1747, 8vo, second edition, *ibid*, 1756; a third has been published since Brucker's death, with a continuation by Professor Born of Leipsic, in 1790. *Miscellanea Historiæ Philosophicæ Literariæ Criticæ olim sparsim edita, nunc uno fasce collecta*, Augsburg, 1748, 8vo. *Erste Anfangsgrunde der philosophischen Geschichte, als ein Auszug seiner grossern Werke, zweyte Ausgabe*, Ulm, 1751, 8vo. He likewise superintended and corrected an edition of Luther's translation of the Old and New Testment, with a Commentary extracted from the writings of the English theologians, Leipsic, 1758–70, folio, six parts. His death ensued before the completion of this work, which has since been accomplished by Teller. He died at Augsburg in 1770; and he may be added to the catalogue of Huetius, to prove that literary labour is not incompatible with sound health and longevity. (See Saxii *Onomasticon; Biographie Universelle;* Gesner's *Isagoge.*)

It is only by his writings on the history of philosophy that Brucker is now known in the literature of Europe. In this study his great work forms an important era, and even at the present day it is the most extensive and elaborate upon the subject. It is, however, a work of which the defects are great, and its errors have been important in their consequences, in proportion to the authority it has acquired. We shall, therefore, hazard a few general observations on the defects which chiefly detract from the perfection and utility of the *Critical History of Philosophy.*

If Brucker had carried into this study a penetration equal to his diligence, and had his general comprehension of the scope and

nature of the subject corresponded with the elaborate minuteness of his details, he would have left us a work which might have had some pretensions to be considered as a rational history of human opinion. He lived, however, at a period when these different qualities were only beginning to be conjoined, and when as yet the history of philosophy had been written merely as a chronicle of the passing theories of individuals and sects. To give to the science of history a regular and connected form, and to arrange the narrative of successive events, and still more of successive opinions, according to the relation they bear to principles of established influence, was an attempt of which few in that age had any conception, and of which Brucker certainly had none. In civil history it was then believed that the historian had fulfilled all the duties of his office if he strung together the events which were known or believed to have occurred, in good language, and garnished them occasionally by a few general reflections on the absolute motives of human action. A very different notion is now held of the functions of the historian. He who at present attempts to write the history of any country must reflect, before he begins, what were the chief occurrences in that history, and what were the revolutions which the manners and constitution of that particular nation have undergone. He must bear with him, from the commencement to the conclusion of his labours, a constant impression that every occurrence should be more or less considered, not only as it took place, and as it bore an influence on contemporary affairs, but as it may have remotely contributed to the events, and the opinions, and the character of succeeding times. But if this be true in regard to the histories of particular nations, it is evident that, by how much the traces of opinions are more light and evanescent than those of events, by how much the speculations of philosophers whose writings have either perished or come down to us mutilated and obscure are more difficult to be appreciated in their causes, and connections, and consequences, than the actions of warriors and statesmen,—by so much the more is it necessary in philosophical than in civil history to combine reasoning with erudition, and to substitute the researches of the philosopher for the details of the chronicler. History and philosophy are two different things; and he who would write the history of philosophy must excel in both. Bacon had long ago required this union, and had pointed out the manner in which the historian of literature should endeavour to establish those principles of connection which constitute the soul and charm of such a history; how, by detecting the union of effects and causes, he might be enabled to determine the circumstances favourable or adverse to the sciences; and how, in short, by a species of enchantment, he might evoke the literary genius of each different age. The fulfilment of this plan was, however, far beyond the capacity of Brucker, and was an undertaking of which he had even no conception. Better qualified by nature and education for amassing than arranging materials, he devoted his principal attention to a confused compilation of facts, leaving to others their application, the discovery of their mutual connections, and the formation of the scattered fragments into a whole.

The merit of his great work consists entirely in the ample collection of materials. The reader who would extract any rational view of the progress of opinion must peruse it with a perpetual commentary of his own thoughts. He will find no assistance from his author in forming any general views, or in tracing the mutual dependencies of the different parts of the subject. Brucker has discovered the fountains of history, but he has made us drink of them without purifying the draught. Even in this respect his merit has been greatly overrated. Vast as is the body of materials which he has collected, we are always missing those very things which we might reasonably have expected would have been the first objects of a rational inquirer, and we are continually disappointed of the information we are most anxious to acquire. The idle and slavish attention which he has bestowed on previous compilers has frequently diverted him from the study of the original authors themselves. Quoting the passages of the ancients from others, or trusting perhaps to the reference of an index, he has frequently overlooked those very testimonies which could have given us the most authentic knowledge of the opinions or characters of ages and individuals. He has often presented the authorities he has adduced, mutilated or misapplied; and this either from not having sufficiently studied these passages in their general connection with the system they illustrate, or from having been unable to withdraw them from the obscurity in which they were involved. He has shown no critical sagacity in distinguishing the spurious from the authentic, or in balancing the comparative weight of his authorities. He has frequently transcribed where he ought to have explained the words of the original authors; and, without taking into account the different value of the same term in different nations and ages, he has left us to apply a doubtful or erroneous meaning to words which might have been easily rendered by other expressions, and to suppose a distinction in the sense where there only existed a difference in the language. The glaring errors, even, which occasionally occur in his expositions of the Grecian philosophy, while they are inconsistent with any critical knowledge of the tongue, would make us suspect that he was in the habit of relying on the treacherous aid of translations. In short, if we knew nothing more of the ancient philosophers than what we acquire from Brucker, we should be often obliged to attribute to them opinions so obscure, or so absurd, that we must either believe ourselves wrong in the interpretation, or be unable to comprehend the cause of all the admiration and reverence they have received.

He has discovered little skill in his analysis of the different systems of philosophy; and the confusion of what is essential and principal with what is accidental and subordinate clearly evinces that these abridgments were thrown together while acquiring, in detail, a knowledge expressly for the purpose, instead of being the consummation of a long and familiar meditation on the subjects in all their modifications and dependencies. He has dwelt with the most irksome minuteness on every unimportant and doubtful circumstance in the lives of the philosophers; but he has too often overlooked the particular and general causes that produced an influence on the destinies of their philosophy. The aphoristic method which he has adopted prevents him from following a consecutive argument throughout its various windings. The most convincing reasoning in his hands loses much of its demonstration and beauty; and every ingenious paradox comes forth from his alembic a mere *caput mortuum*,—a residue from which every finer principle has been expelled. Where the genius of the philosopher is discovered more in the exposition and defence than in the original selection and intrinsic stability of his tenets, Brucker has not found the art of doing justice both to the philosopher and to his opinions, or of conveying to the reader any conception of the general value of the original. This last defect, it must, however, be acknowledged, is more or less inseparable from every abstract of opinions, where it is always necessary to separate in some degree what is essential to the subject from what is peculiar to the man. He has relieved the sterility of his analysis by none of the elegancies of which the subject was susceptible. Without any pretension to purity, his diction is defective even in precision; and his sentences, at all times void of harmony and grace, are abrupt, and often intricate in their structure. (W. H.)

BRUGES (in Flemish BRUGGE), a city of Belgium, the capital of West Flanders, is situated in the midst of a fertile plain, intersected by the canals of Ghent, Ostend, and Sluys, in 51° 12′ N. lat. and 3° 13′ E. long. It is, in a direct line, about 7 miles from the sea, 12 miles E. of Ostend, 24 N.W. of Ghent, and 60 miles in the same direction from Brussels. The history of Bruges dates from about the 3d century of the Christian era. In the 7th it had emerged into importance; and its corporation of weavers, which afterwards in its best days numbered 50,000 men, was already highly renowned in the time of Charlemagne. In the 9th century Bruges became subject to the counts of Flanders, who resided there, and made the city one of the most populous and wealthy in Europe by the great advantages and immunities which they offered to merchants and manufacturers. The inhabitants guarded with the most jealous care the privileges which they sometimes received and sometimes exacted from their rulers, and not unfrequently rose in arms for their defence. Though Bruges, and Ghent, and other Flemish towns owned a common lord, their interests were never identified, and they seldom let an opportunity pass of doing each other as much injury as possible. In the middle of the 14th century Bruges passed by marriage into the hands of the dukes of Burgundy, under whom it reached the highest point of its prosperity. The magnificence of the Flemish court was such that no European monarch could equal or approach it. When the wife of Philip the Fair of France visited Bruges at the beginning of the 14th century, "There are hundreds here," she exclaimed, "who have more the air of queens than myself;" and to such an extent was this extravagance ultimately carried that Charles V. was obliged, in the 16th century, to repress it by severe sumptuary laws. In 1430 Philip the Good, duke of Burgundy, instituted at Bruges the chivalric order of the Golden Fleece, a compliment to the town, no small portion of whose prosperity arose from its woollen trade. In the 14th and 15th centuries, Bruges was the chief emporium of the cities of the Hanseatic league; and merchants from every quarter of the world found there a ready market for their

goods. The argosies of Venice and Genoa came laden with the produce of the East; ships of every nation took in and discharged their cargoes at the quays; the warehouses were filled with bales of wool from England, and with silk from Persia. Not the least famous of the manufactures was that of tapestry, in which the people of Bruges acquired great skill a century before the looms of Beauvais or the Gobelins were set up. The prosperity of Bruges was undiminished till it passed under the dominion of the house of Hapsburg. For a violation of some of their prerogatives, the inhabitants imprisoned the Archduke Maximilian in 1488, and a terrible vengeance was inflicted upon the town for this outrage. Its trade was transferred to Antwerp, and its ruin was ultimately completed by the religious persecutions of the bloody duke of Alva at the end of the 16th century. Such of the inhabitants as escaped with their lives fled to England and introduced into that country many of the arts and manufactures which they and their forefathers had cultivated with success for many generations. In more modern times the town has frequently suffered from the effects of war. In 1704 it was besieged by the Dutch, and in 1708 and 1745 it was captured by the French. The contrast between the Bruges of the 15th century and the Bruges of recent times is as striking as it is painful. As Wordsworth says—

> "In Bruges town is many a street
> Whence busy life hath fled,
> Where, without hurry, noiseless feet
> The grass-grown pavement tread."

The great circumference of the city, its numerous squares and streets, and the number and magnificence of its public buildings, all attest its former importance; while the comparative absence of commercial activity, and the general air of desolation, bear witness to its present insignificance. Its trade has, however, considerably revived during the present century, and its great advantages in canal and railway communication, its spacious docks and excellent quays, and the great fertility of the surrounding country, are once more restoring it to its high place among cities. Of the public buildings of Bruges the most remarkable are the Church of Nôtre Dame, containing a sculpture of the Virgin and Child, said to be by Michel Angelo, effigies in copper of Charles the Bold and Mary of Burgundy, who are buried in the church; the cathedral of St Sauveur, built of brick, but internally the handsomest church in Bruges, with some fine pictures by Hemling (or, more correctly, Memling,—see *Athenæum*, No. 2513) and Peter Porbus; the hospital of St John, a charitable institution, where sick persons are attended by the sisters of charity; the exchange, which is the oldest in Europe; the courthouse, a fine building, partly on the site of the old palace of the counts of Flanders; and the Hôtel de Ville, a small but handsome edifice, dating from 1377 and restored in the present century, in the niches of which there were formerly statues of the old counts of Flanders, which were destroyed by the French revolutionists in 1792. The belfry-tower in the great square, of which Longfellow sings so finely, is the most beautiful structure of the kind in Europe, and its chimes are the best in Belgium. It was erected at the end of the 14th century, and is still used for communicating the alarm of fire by a flag or a light to all parts of the city. In this same square is a house in which Charles II. resided during his exile from England. Among the conventual establishments the most important are the Béguinage and the English nunnery. The town is likewise well provided with the means of education. There is a medical school, to which is attached a museum of natural history and a botanical garden. For the higher departments of school training there is an excellent athenæum, annually subsidized by Government, besides a theological seminary, a school of navigation, and an institution for the deaf and dumb and blind. The academy of painting is in a very flourishing condition, and offers many advantages to the student, as instruction is given gratis in drawing and architecture. The public library in the town-hall contains upwards of 15,000 volumes. The charitable institutions of Bruges are both numerous and well organized. They are all the more necessary, that the number of persons in the city requiring support is unusually great. In the poorhouse alone there is accommodation for nearly 600 individuals, and it is almost always completely filled. The most important manufacture in Bruges is that of lace. The other manufactures consist of linens, woollen and cotton goods, soap, leather, tobacco, starch, pottery, and bells. There are also some small breweries and distilleries, and dyeing and bleaching establishments; and ship-building is also carried on. The exports from Bruges comprise the products of the rich agricultural district that surrounds the town; the imports include metals, dyewoods, wines, fruits, oil, cotton, and wool. Despite the number of canals, the inhabitants of Bruges are very ill supplied with water for domestic purposes; every house is accordingly provided with a tank or butt to receive rain-water. The quantity collected in the public tanks is distributed through the city in pipes. Of the canals the largest is that to Ostend, wide and deep enough to allow vessels of 500 tons to pass up from the sea. The ramifications of these canals intersect the city in all directions, and are crossed by upwards of fifty bridges, whence the name of the town is derived. Population in 1838, 44,374; in 1846, 49,308; in 1851, 50,698; in 1866, 49,819.

See Weale's *Bruges et ses environs*, 1865; Gilliodts van Severen, *L'Inventaire des archives de la ville de Bruges*, 3 vols.

BRUMATH, or BRUMPT, a town of Lower Alsace, in the circle of Strasburg, on the River Zorn. It has a castle and mineral wells, and occupies the site of the ancient Brucomagus. Population in 1871, 5619.

BRUNCK, RICHARD FRANÇOIS PHILIPPE (1729–1803), a French scholar, was born at Strasburg, 20th December 1729. He was educated at the Jesuits' college at Paris, but having early entered the public service, he soon forgot his Latin and Greek. At the age of thirty he returned to his native town and resumed his studies, paying special attention to Greek. The nature of the office which he held put considerable sums of money at his disposal, which he expended in publishing editions of the Greek classics. The first work which he edited was the *Anthologia Græca*, in which his innovations on the established mode of criticism startled European scholars; for wherever it seemed to him that an obscure or difficult passage might be made intelligible and easy by a change of text, he did not scruple to make the necessary alterations, whether the new reading were supported by manuscript authority or not. With the assistance of Schweighäuser, then an unknown youth, he next brought out editions of the Greek dramatists, characterized by the same peculiarities as the *Anthologia*, and ultimately the *Gnomici Poetæ Græci*. In 1781 he published an edition of *Virgil*, for which he was pensioned by the French king. At the outbreak of the French Revolution, in which he took an active part, he lost his pension, and was reduced to such extremities that he was obliged to sell a portion of his library. In 1802 his pension was restored to him, but too late to prevent the sale of the remainder of his books. He had brought out an edition of *Plautus* in 1788, and was in the act of republishing it when he died, June 12, 1803.

BRUNDUSIUM, or BRUNDISIUM. See BRINDISI.

BRUNEL, ISAMBARD KINGDOM (1806–1859), one of the most distinguished civil engineers of the age, was born at Portsmouth, April 9, 1806. He was the only son of Sir

Marc Isambard Brunel, from whom he inherited some rare intellectual gifts, and to whom he owed his first education. From his earliest years he took an eager and intelligent interest in all the plans and undertakings of his father, who had then just completed the construction of the remarkable block machinery at Portsmouth. He displayed in childhood singular powers of mental calculation, great skill and rapidity as a draughtsman, and a true feeling for art. After attending some private schools, he was sent at the age of fourteen to Paris, to study mathematics, and to recover his knowledge of French. From November 1820 to August 1822 he studied at the Collége Henri Quatre; and in holiday intervals he used to visit the engineering works going on in Paris, and send his father drawings and descriptions of them. In 1823 he entered his father's office as assistant-engineer, just at the time when the project of the Thames Tunnel began to occupy the attention of Sir Isambard; and from 1825, when the work was begun, till 1828, when it was stopped by an irruption of the river, he displayed a singular energy, inventiveness, and power of application in that struggle of science against natural obstacles on a vast scale. He had even then the power, which distinguished him in later years, of doing almost without sleep for many nights when work was pressing. During the later part of the contest which ended by a second irruption in January 1828, he was both nominal and actual resident engineer of the Thames Tunnel. Left for nearly two years without regular professional occupation, Brunel employed himself in scientific researches, enjoying intercourse with Babbage, Faraday, and other friends. In November 1829 he sent in designs and plans for the projected Suspension Bridge over the Avon at Clifton. In consequence of objections raised by Telford, the referee of the bridge committee, Brunel's plans were rejected. But on a second competition, early in 1831, he sent in a new design, and this was accepted. Brunel was appointed engineer to the trustees, and the works were begun in 1836. Delay had been caused by want of funds, and from the same cause the works were afterwards suspended for some years, and were not completed during Brunel's lifetime. In March 1833, Brunel, at the age of twenty-seven, attained one of the highest professional positions by his appointment as engineer of the newly-projected Great Western Railway. For several years his energies were taxed to the utmost by the conflict with obstructive landowners and short-sighted critics; but he showed himself equal to the occasion, not only as a professional man, but as a persuasive negotiator. For solidity of construction and for skill and beauty of design the Great Western Railway, though one of the first made in England, holds a very high place. Among the triumphs of the engineer are the Hanwell Viaduct, the Maidenhead Bridge, and the Box Tunnel, at the time the longest in the world; and, on extensions of the line, the great bridges at Chepstow and Saltash. The now notorious "battle of the gauges" took its rise from Brunel's introduction of the broad gauge on this line. In 1846 he resigned his office as engineer of the Great Western Railway. In 1844 he had recommended the adoption of the Atmospheric System on the South Devon Railway, but after a year's trial this system was abandoned. The last and greatest of Brunel's railway works was the Royal Albert Bridge of the Cornwall Railway, crossing the River Tamar at Saltash. This work, sanctioned by parliament in 1845, was constructed between 1853 and 1859. In addition to the arduous labours of railway engineering, Mr Brunel had taken a leading part in the systematic development of ocean steam navigation. As early as October 1835 he had suggested, to the amusement of the directory of the Great Western Railway, that they should "make it longer, and have a steamboat to go from Bristol to New York, and call it the Great Western." The project was taken up, and the "Great Western" steamship was designed by Brunel, and built at Bristol under his superintendence. It was much longer than any steamer of the day, and was the first steamship built to make regular voyages across the Atlantic. While the vessel was building a controversy was raised about the practicability of Brunel's scheme, Dr Lardner asserting dogmatically that the voyage could not be made, and backing his assertion with an array of figures. His view was widely accepted, but the work went on, and the voyage was accomplished in 1838. A greater work was at once undertaken, and the "Great Britain" was built. This was the first large iron steamship, the largest ship afloat at that time, and the first large ship in which the screw-propeller was used. She made her first voyage from Liverpool to New York in August and September 1845; but in the following year was carelessly run upon the rocks in Dundrum Bay on the coast of Ireland. After lying there nearly a year without material damage she was got off and was employed in the Australian trade. Brunel soon after began to meditate a vaster project still, the construction of a vessel large enough to carry all the coal required for a long voyage out, and if coal could not be had at the out port, then to carry enough also for the return voyage. It seemed to him, further, that a great increase of size would give many advantages for navigation. During his connection as engineer with the Australian Mail Company he worked out into a practical shape his conception of a "great ship;" and in 1852 his scheme was laid before the Directors of the Eastern Steam Navigation Company. It was adopted, the projector was appointed their engineer, and after much time occupied about contracts and specifications, the work was begun in December 1853. Immense difficulties in the progress of construction caused delays from time to time. The operations of launching was several times attempted in vain; but at length the gigantic vessel, the now familiar "Great Eastern," was got afloat (31st January 1858). Much remained to be done to complete the ship; and her engineer, overworked and worn out with the worry of the launching processes, broke down and did not live to see her sail on her first voyage. In addition to the great works already described, Brunel was employed in the construction of many docks and piers. The first of these was the Monkwearmouth Docks, for which he made the designs in 1831. The construction, after a new design, was begun in 1834. He was afterwards engaged in works of the same kind at Bristol, Plymouth, Briton Ferry, and Brentford, and on a pier at Milford Haven. He was a zealous promoter of the Great Exhibition of 1851, and was a member of the committee on the section of machinery and of the building committee. He paid much attention to the subject of improvement of large guns, and designed a floating gun-carriage for the attack on Cronstadt in the Russian war (1854); he also designed and superintended the construction of the hospital buildings at Renkioi, on the Dardanelles (1855). The genius, energy, and industry of Brunel in his profession were not more remarkable than the high moral tone which characterized his whole life, and the fascinating qualities which gave him immense personal influence, and made him the delight of the social circle. With single-hearted truthfulness he devoted himself to his chosen work; he was singularly free from professional jealousy, and was always ready to commend and help others. With robust health, which he enjoyed through many years, he had the two invaluable qualities of good spirits and good temper. In his relations with his subordinates he was considerate and kindly, at the same time that he demanded faithful service according to a high standard. He cared nothing for popularity. He enjoyed

the beauties of a fine landscape, and was an enthusiastic lover of the fine arts. In the course of his busy life he several times went to Italy and Switzerland; and in 1847 he bought a small estate in Devonshire, to make his home there. The pressure of business, however, did not allow him to spend much of his time in the country. In 1830 Brunel was elected F.R.S., and he was afterwards a member of many other scientific societies. In 1857 the honorary degree of D.C.L. was conferred on him by the university of Oxford. In July 1836 he married; he left two sons and a daughter surviving him. For the sake of his health he spent the winter of 1858-59 in Egypt, returning to England in May. He was on board his "great ship" on the 5th September 1859, and the same day was attacked with paralysis. The ship sailed on her first voyage on the 7th, and her great projector passed away on the 15th of the month. His remains were interred in Kensal Green Cemetery. In 1870 appeared *The Life of I. K. Brunel, C.E.*, by his son Isambard Brunel, of Lincoln's Inn, chancellor of the diocese of Ely. (W. L. R. C.)

BRUNEL, Sir Marc Isambard (1769-1849), was born at Haqueville, in Normandy. His family had for several centuries held a respectable station in the province, living as farmers and small landowners on the estate on which he was born, and numbering among its members Nicholas Poussin. He was educated at the seminary of St Nicaise at Rouen, with the intention of his entering holy orders; but his predilection for the physical sciences was so strong, and his genius for mathematics and mechanics so decided, that, on the advice of the superior of the establishment, he was removed to follow a more congenial career. His father then destined him for the naval service, which he entered on the appointment of the Marshal de Castries, the minister of marine, and made several voyages to the West Indies. In this position, although only in his seventeenth year, his mechanical talents developed themselves actively on many occasions, and he surprised his captain by the production of a sextant of his manufacture with which he took his observations. On his return to France in 1792, he found the Revolution at its height, and like all who entertained royalist principles, he was compelled to seek safety in emigration. He effected his flight with considerable difficulty, and found refuge in the United States of America, where, driven by necessity to the exercise of his talents as a means of support, he followed the bent of his inclination and became a civil engineer and architect. His first engagement was on the survey of a tract of land near Lake Erie; he then became engaged in cutting canals, and was employed to erect an arsenal and cannon foundry at New York, where he applied several new and ingenious machines. His highly ornamental design for the House of Assembly at Washington was rejected, as being inconsistent with the simplicity of a republic; he was, however, engaged to design and superintend the construction of Bowery Theatre, New York, since destroyed by fire, the roof of which was peculiar and original.

The idea of substituting machinery for manual labour in the making of ships' blocks had long occupied his mind; and, in 1799, having matured his plans, he determined to visit England. Earl St Vincent was at that time at the head of the Admiralty, and after the usual delays and difficulties, which were ultimately overcome chiefly through the powerful influence of his steady friend and patron Earl Spencer, aided by the recommendation of Brigadier-General Sir Samuel Bentham, who at once perceived and appreciated the merit of the machines and the talent of the inventor, the system was adopted, and the machinery erected. The construction of the machines was entrusted to Mr Henry Maudslay, whom Brunel had selected with true discrimination, and by whom he was ably assisted. The beautiful simplicity of these machines, their perfect adaptation to their various purposes, and, notwithstanding the recent advances in mechanics, their continuing for nearly half a century in active work, without any improvements having ever been suggested, must rank them as among the most complete and ingenious pieces of mechanism ever invented.

The block machinery was completed in 1806, and it was estimated that the economy produced by it in the first year was about £24,000, two-thirds of which sum was awarded to the ingenious inventor, who was soon after engaged by the Government to erect extensive saw-mills, on improved principles, at Chatham and Woolwich. He there suggested modifications of the systems of stacking and seasoning timber, which were afterwards carried into effect. Some time previously, he had invented the ingenious little machine for winding cotton-thread into balls, which, simple as it may at first sight appear, has exercised great influence on the extension of the cotton trade.

He found time also to invent an instrument for combining the use of several pens, so as to produce simultaneously a number of copies of a manuscript; a simple and portable copying-machine; and a contrivance for making the small boxes used by druggists, which had been previously imported in large quantities from Holland. A nail-making machine also occupied his attention; and he discovered the system of giving the efflorescent appearance to tinfoil, by which it was fitted for ornamental purposes. Among other more important improvements may be mentioned that of cutting veneers by circular saws of large diameter, to which is mainly due the present extensive application of veneers of wood to ornamental furniture. About the year 1812 he had devised a scheme for making shoes by machinery; and, under the countenance of the duke of York, the shoes so manufactured, in consequence of their strength, cheapness, and durability, were introduced for the use of the army; but at the peace in 1815, manual labour becoming cheaper, and the demand for military equipments having ceased, the machines were laid aside.

Steam navigation also attracted his attention, and he became deeply interested in establishing the Ramsgate steam vessels, which were among the first that plied successfully on the River Thames; and on board of them it is believed that the double engines were first used. About this period, after much labour and perseverance, he induced the Admiralty to permit the application of steam for towing vessels to sea, the practicability of which he had strenuously urged. The experiments were tried chiefly at his own expense; a small sum in aid had been promised, but it was eventually withdrawn before the completion of the trials, the Admiralty considering the attempt "too chimerical to be seriously entertained." He introduced various improvements in the steam-engine, and for nearly ten years persevered in the attempt to use liquefied gases as the source of motive power, in which he was ably assisted by his son. The necessary experiments were most laborious, and needed all the persevering energy and resources of a mind determined not to be foiled; in spite, however, of his efforts, after a great sacrifice of time and money, the plan was abandoned.

The whole power of his mind, however, was for many years concentrated on one great object, the construction of the tunnel for communication from shore to shore beneath the bed of the River Thames. It is said that the original idea occurred to him, as applied to the Neva at St Petersburg, in order to avoid the inconvenience arising from the floating ice,—a plan which he offered to the Emperor Alexander, on the occasion of his visit to England in 1814. Undismayed by previous signal failures in the attempt

to construct a tunnel beneath the Thames, Brunel, confident in his own powers, persevered, and in 1824, under the auspices of the duke of Wellington, who always entertained a favourable view of the practicability of the scheme, a company was formed for its execution; and after numerous accidents and suspensions of the works, this great and novel undertaking was successfully accomplished, and the tunnel opened to the public in the year 1843.

In the prosecution of the work he received great assistance from his son, Isambard Kingdom Brunel, and in a scientific point of view the construction of the tunnel will be regarded as displaying, at the same time, the highest professional ability, an amount of energy and skill rarely exceeded, and a fertility of invention and resources, under what were deemed insurmountable difficulties, which will secure to the memory of Sir Isambard Brunel a high position among the engineers of England.

He received the order of the Légion d'Honneur in 1829, and the honour of knighthood in 1841. He was a corresponding member of the French Institute, and a fellow of the Royal Society. He joined the Institution of Civil Engineers in the year 1823, and constantly attended the meetings, took part in the discussions, and promoted the society's interests by every means in his power.

He was unaffected and simple in his habits, and possessed indomitable courage, perseverance, and industry; whilst his benevolence constantly prompted him to kindly and considerate actions. His labours had so seriously impaired his health, that for some years after the completion of the tunnel he was unable to mix in active life. He died on the 12th of December 1849, in his 81st year. (See Richard Beamish, *Memoirs of Sir Marc Isambard Brunel*, 1862.)

BRUNELLESCHI, Filippo, (1377–1446), one of the greatest Italian architects, the reviver in Italy of the Roman or Classic style, was born at Florence in 1377. His father, a notary, had destined him for his own profession, but observing the boy's talent for all sorts of mechanism, placed him in the guild of goldsmiths. Filippo quickly became a skilled workman, and, eagerly desirous to excel, perfected himself in the knowledge of sculpture, perspective, and geometry,—whatever, in short, was useful for the architectural art, to which he found himself attracted. He designed some portions of houses in Florence, and in 1401 he was one of the competitors for the design of the gates of the baptistery of San Giovanni. He was unsuccessful, though his work obtained praise, and he soon afterwards set out for Rome. He studied hard, and resolved to do what he could to revive the older classical style, which had died out in Italy. In 1407 he returned to Florence, just at the time when it was resolved to attempt the completion of the cathedral church of Santa Maria del Fiore. Brunelleschi's plan for effecting this by a cupola was approved, but it was not till 1419, and after innumerable disputes, that the work was finally entrusted to him. At first he was hampered by his colleague Ghiberti, of whom he skilfully got rid. He did not live to see the completion of his great work, and the lantern on the summit was put up not altogether in accordance with the instructions and plans left by him. The great cupola, one of the triumphs of architecture, exceeds in some measurements that of St Peter's at Rome, and has a more massive and striking appearance. Besides the masterpiece Brunelleschi executed numerous other works, among the most remarkable of which are the Pitti Palace at Florence, and the churches of San Lorenzo and Spirito Santo, and the still more elegant Capella dei Pazza. He died in 1446, and was buried in the great church of Santa Maria. See Architecture, vol. ii. p. 436.

BRUNET, Jacques Charles, the eminent bibliographer, was born at Paris in 1780, and died in 1867. He was the son of a bookseller, and at an early age began the study which occupied the whole of his after life. In 1802 he printed a supplement to the *Dictionnaire Bibliographique* of Duclos and Cailleau, and in 1810 there appeared the first edition of his *chef-d'œuvre*, the *Manuel du Libraire*. With the exception of a few pamphlets and minor dissertations, Brunet published nothing beyond successive editions of his great bibliographical dictionary, which had come to be recognized as the first book of its class in European literature. The last (fifth) edition in six volumes was completed in 1865.

BRUNI, Leonardo (1369–1444), author of the *History of Florence*, was an eminent scholar of the 15th century. He was born at Arezzo, and is generally known as L. Aretino. He was secretary to the papal chancery under Innocent VII. and John XXII. From 1427 to his death in 1444 he was chancellor to the republic of Florence. He was buried at the expense of the state in Sta. Croce, where his laurelled statue is still to be seen. His *History of Florence* comes down to 1404.

BRÜNN, the capital of the Austrian margraviate of Moravia, is situated for the most part between two hills at the confluence of the Schwarzawa and the Zwittawa, 69 miles N. of Vienna and 115 W.S.W. of Prague, with both of which it is connected by railway. Lat. 49° 11′ 39″ N., long. 16° 39′ 35″ E. On one of the hills known as the Spielberg stands the castle of the same name, which has long been used as a prison, and is famous for its connection with the patriotic Silvio Pellico, who was confined within its walls for about eight years. The old town, which is comparatively small, still retains some of its fortifications, but most of them have given place to promenades. Its streets are narrow and crooked but well-paved, and it contains many of the most important buildings in the city. Extensive suburbs have grown up around it, and since 1849 form portions of the same commune. There are fine public gardens and a large park known as the Augarten, presented to the town by the Emperor Joseph II. The Rathhaus, which dates from 1511, has a fine Gothic portal, and contains several interesting antiquities. The ecclesiastical buildings comprise the cathedral of St Peter's, situated on the lower hill; the fine Gothic church of St James, built in the 15th century, with its iron tower added in 1845, and a remarkable collection of early typography; the church of the Augustine friars, dating from the 14th century; that of the Minorites with its frescoes, its holy stair, and its Loretto-house; the bishop's palace; a splendid Jewish synagogue; and several monastic establishments. As the capital of the province Brünn is the seat of the chief legal and military courts, and thus possesses various official edifices, the old Jesuit convent having been turned into barracks. It is also the seat of a Roman Catholic bishop and of a Protestant consistory. Its educational and benevolent institutions comprise a theological seminary, a gymnasium, several academies and schools, an agricultural society, a botanic garden, an infirmary, an orphanage, a blind asylum, a deaf-mute institution, a lunatic asylum, and several hospitals, of which the most important is the great hospital of St Anna. The national museum for Moravia and Silesia, though comparatively poor, must also be mentioned. Brünn is one of the chief seats of the woollen manufacture in the Austrian dominions, and the centre of a large miscellaneous trade. Considerable quantities of silk and cotton goods are manufactured, as also leather, paper, tobacco, oil, and sugar. There are also steam-flour-mills, engineering works, and breweries. There is a remarkable viaduct in the immediate neighbourhood of the town. Brünn probably dates from the 9th century. In the 11th it was bestowed by Duke Wratislas II. on his son Otto. Brünn is a place of great

strength, and held out successfully against sieges—in 1428 by the Hussites, in 1467 by King George of Bohemia, in 1645 by the Swedish general Torstenson, and in 1742 by the Prussians. In 1805 it was the headquarters of Napoleon before the battle of Austerlitz. Its population in 1869 was 73,771.

BRUNO, St, the founder of the Carthusian order of monks, was born at Cologne about the year 1030. He was educated at Cologne, and afterwards at Rheims, where he was appointed to superintend the studies in all the chief schools of the diocese. Many of his pupils afterwards became distinguished, and in the number was Pope Urban II. In 1084, after some disputes with Manasses, the archbishop of Rheims, he retired with six companions into the desert of Chartreuse, where he built an oratory, with cells at a little distance from each other. Six years afterwards he went to Rome, where Urban II. pressed him to accept the archbishopric of Reggio. He declined the honour, and withdrew into the solitudes of Calabra, where he died October 6, 1101. He wrote treatises on the Psalms and on some of the Epistles, but none of his works are extant. His canonization took place in 1514. (See Mrs Jameson's *Legends of the Monastic Orders*, 124–134; Butler's *Lives of the Saints*, vol. ii. 592.) This saint is not to be confounded with others of the same name,—the bishop and apostle of the Prussians (970–1008), and the great archbishop of Cologne (925–968).

BRUNO, Giordano, the most genial and interesting of the Italian philosophers of the Renaissance, was born at Nola about the year 1548. Little is known of the life of this knight-errant of philosophy; the very date of his birth rests in obscurity. What we do know is attractive enough to render it matter of regret that the materials should be so scanty. In his fifteenth year he entered the order of the Dominicans at Naples, and is said to have composed a treatise on the ark of Noah. Why he should have submitted to the bonds of a discipline palpably unsuited to his fiery and vehement spirit, we cannot tell. He soon found the restraints intolerable, and became an outcast from his church and a wanderer on the face of the earth. His opinions with regard to some of the Romish mysteries seem to have been too liberal to find toleration with so strict an order as that of St Dominic. He was accused of impiety, and after enduring persecution for some years, he fled from Rome about 1576, and wandered through various cities, reaching Geneva in 1577. The home of Calvinism was no resting-place for him, and he travelled on through Lyons, Toulouse, and Montpellier, arriving at Paris in 1579. Everywhere he bent his irrepressible energies to the exposition of the new thoughts which were beginning to effect a revolution in the thinking world. He had drunk deeply of the very spirit of the Renaissance, the determination to open his eyes and see for himself this noble universe, unclouded by the mists of authoritative philosophy and church tradition. The discoveries of Copernicus, which were unhinging men's minds and teaching them to look upon their little world in a new light, were eagerly accepted by him, and he used them as the lever by which to push aside the antiquated system that had come down from Aristotle, and which was loaded with the weight of that great thinker's name. For Aristotle, indeed, he had a perfect hatred. Like Bacon and Telesius he infinitely preferred the older Greek philosophers, who had looked at nature for themselves, and whose speculations had more of reality in them. He had read widely and deeply, and in his own writings we come across many expressions familiar to us in earlier systems. Yet his philosophy is no eclecticism. He owed something to Lucretius, something to the Stoic nature-pantheism, something to Anaxagoras, to Heraclitus, to the Pythagoreans, and to the Neo-platonists, who were partially known to him; above all, he had studied deeply and profoundly the great German thinker Nicolas of Cusa, who was indeed a speculative Copernicus. But his own system has a distinct unity and originality; it breathes throughout the fiery spirit of Bruno himself.

Bruno had been well received at Toulouse, where he had lectured on astronomy; even better fortune awaited him at Paris. He was offered a chair of philosophy, provided he would receive the Mass. He at once refused, but was permitted to deliver lectures. These seem to have been altogether devoted to expositions of a certain logical system which Bruno had taken up with great eagerness, the *Ars Magna* of Raymond Lully. With the exception of a comedy, *Il Candelajo*, all the works of this period are devoted to this logic. The most important of them is the treatise *De Umbris Idearum*. It has seemed to many a curious freak of Bruno's that he should have so eagerly adopted a view of thought like that of Lully, but in reality it is in strict accordance with the principles of his philosophy. Like the Arabian logicians, and some of the scholastics, who held that ideas existed in a threefold form,—*ante res*, *in rebus*, and *post res*,—he laid down the principle that the archetypal ideas existed metaphysically in the ultimate unity or intelligence, physically in the world of things, and logically in signs, symbols, or notions. These notions were the shadows of the ideas, and the *Ars Magna* furnished him with a general scheme, according to which their relations and correspondences should be exhibited. It supplied not only a *memoria technica*, but an *organon*, or method by which the genesis of all ideas from unity might be represented intelligibly and easily. It provided also a substitute for either the Aristotelian or the Ramist logic, which was an additional element in its favour.

In the train and under the protection of the French ambassador, Michel de Castelnau, Bruno passed over in 1583 to England, where he resided for about two years. He was much disgusted with the brutality of the English manners, which he paints in no flattering colours, and he found in Oxford pedantry and superstition as rampant as at Geneva. But he indulges in extravagant eulogies of Elizabeth, and he formed the acquaintance at London of Sir Philip Sidney, Fulke Greville, and other eminent Englishmen. At Oxford he was allowed to hold a disputation with some learned doctors on the rival merits of the Copernican and so-called Aristotelian systems of the universe, and, according to his own report, had an easy victory. The best of his works were written in the freedom of English social life. The *Cena de le Ceneri*, or Ash Wednesday conversation, devoted to an exposition of the Copernican theory, was printed in 1584. In the same year appeared his two great metaphysical works, *De la Causa, Principio, ed Uno*, and *De l'Infinito, Universo, e Mondi*; in the year following the *Eroici Furori* and *Cabala del Cavallo Pegaseo*. In 1584 also appeared the strange dialogue, *Spaccio della Bestia Trionfante*, or *Expulsion of the Triumphant Beast*, an allegory treating chiefly of moral philosophy, but giving at the same time the very essence and spirit of Bruno's philosophy. The gods are represented as resolving to banish from the heavens the constellations, which served to remind them of their evil deeds. In their places are put the moral virtues. The first of the three dialogues contains the substance of the allegory, which, under the disguise of an assault on heathen mythology, is a direct attack on all forms of anthropomorphic religion. But in a philosophical point of view the first part of the second dialogue is the most important. Among the moral virtues which take the place of the beasts are Truth, Prudence, Wisdom, Law, and Universal Judgment, and in the explanation of what these mean Bruno unfolds the very inner essence of his system. Truth is the unity and

substance which underlies all things; Prudence or providence is the regulating power of truth, and comprehends both liberty and necessity; Wisdom is providence itself in its supersensible aspect —in man it is reason which grasps the truth of things; Law results from wisdom, for no good law is irrational, and its sole end and aim is the good of mankind; Universal Judgment is the principle whereby men are judged according to their deeds, and not according to their belief in this or that catechism. Mingled with his allegorical philosophy are the most vehement attacks upon the established religion. The monks are stigmatized as pedants who would destroy the joy of life on earth, who are avaricious, dissolute, and the breeders of eternal dissensions and squabbles. The mysteries of faith are scoffed at. The Jewish records are put on a level with the Greek myths, and miracles are laughed at as magical tricks. Through all this runs the train of thought resulting naturally from Bruno's fundamental principles, and familiar in modern philosophy as Spinozism, the denial of particular providence, the doctrine of the uselessness of prayer, the identification in a sense of liberty and necessity, and the peculiar definition of good and evil. Altogether the *Spaccio*, as it is the most popular, is the most characteristic of Bruno's works.

In 1586 he returned to Paris with Castelnau, but was soon driven from his refuge, and we next find him at Marburg and Wittenberg, the headquarters of Lutheranism. There is a tradition that here or in England he embraced the Protestant faith; nothing in his writings would lead one to suppose so. Several works, chiefly logical, appeared during his stay at Wittenberg. In 1588 he went to Prague, then to Helmstadt. In 1591 he was at Frankfort, and published three important metaphysical works, *De Triplici Minimo et Mensura; De Monade, Numero, et Figura; De Immenso et Innumerabilibus*. He did not stay long at Prague, and we find him next at Zurich, whence he accepted an invitation to Venice. It was a rash step. The emissaries of the Inquisition were on his track; he was thrown into prison, and in 1593 was brought to Rome. Seven years were spent in confinement. On the 9th February 1600 he was excommunicated, and on the 17th was burned at the stake.

As has been said, for an estimation of Bruno's philosophy, the most important works are the two Italian dialogues and the three last-mentioned Latin treatises. It is not an easy matter to put his opinions into small compass, for the general form of exposition adopted by him, the dialogue, imposes a certain looseness on his own mode of thinking.

To Bruno as to all other great thinkers, the end of philosophy is the search for unity. Amid all the varying and contradictory phenomena of the universe there is something which gives coherence and intelligibility to them. Nor can this unity be something apart from the things; it must contain in itself the universe, which develops from it; it must be at once all and one. This unity is God, the universal substance,—the one and only principle, or *causa immanens*,—that which is in things and yet is distinct from them as the universal is distinct from the particular. He is the efficient and final cause of all, the beginning, middle, and end, eternal and infinite. By his action the world is produced, and his action is the law of his nature, his necessity is true freedom. He is living, active intelligence, the principle of motion and creation, realizing himself in the infinitely various forms of activity that constitute individual things. To the infinitely actual there is necessary the possible; that which determines involves somewhat in which its determinations can have existence. This other of God, which is in truth one with him, is matter. The universe, then, is a living cosmos, an infinitely animated system, whose end is the perfect realization of the variously graduated forms.

The unity which sunders itself into the multiplicity of things may be called the *monas monadum*, each thing being a *monos* or self-existent, living being, a universe in itself. Of these monads the number is infinite. The soul of man is a thinking monad, and stands mid-way between the divine intelligence and the world of external things. As a portion of the divine life, the soul is immortal. Its highest function is the contemplation of the divine unity, discoverable under the manifold of objects.

Such is a brief summary of the principal positions of Bruno's philosophy. It seems quite clear that in the earlier works, particularly the two Italian dialogues, he approached more nearly to the pantheistic view of things than in his later Latin treatises. The unity expounded at first is simply an *anima mundi*, a living universe, but not intelligent. There is a distinct development traceable towards the later and final form of his doctrine, in which the universe appears as the realization of the divine mind.

The Italian works of Bruno, formerly exceedingly rare, have been collected and published in two volumes, by A. Wagner, 1830. An edition of the Latin works was begun by Gfrörer in 1834, but has not been completed. The most complete monograph on him is that by C. Bartholmess, 2 vols. 1846–47; the most recent life is that by Domenico Berti, 1868. The best systematic account of his philosophy is that by Carriere, *Philosophische Weltanschauung der Reformationszeit*, 1847, pp. 411–494. The relations between his philosophy and that of Cusanus are treated in Clemens, *G. Bruno und Nicolaus von Cusa*, 1847. An English translation by Morehead (not, as is generally supposed, by Toland) of the *Spaccio* is dated 1713. It was probably printed before that time, and it is now excessively rare. Toland translated the preface to *De l'Infinito*; it is found in his *Posthumous Works*. There is a French translation of part of the *Spaccio*, *Le Ciel Reformé*, 1750. Lasson has translated *De la Causa* into German, 1872, with introduction and notes.

The earlier literature with regard to Bruno is copious; it will be found in Bayle, Buhle, and Tennemann. (R. AD.)

BRUNSWICK (German BRAUNSCHWEIG), a duchy and state of Northern Germany, forming part of the new German Empire, and included in the Prusso-German Zollverein. It consists of three larger and five smaller portions of territory lying mainly between 51° 38′ and 52° 28′ N. lat., and between 9° 20′ and 11° 30′ E. long. The principal part, containing the cities of Brunswick, Wolfenbüttel, and Helmstedt, is situated between Hanover and Prussia, to the S.E. of the former, and has its surface diversified by hill and plain. The part containing Holzminden and Gandersheim extends eastward from the Weser to Goslar, and is intersected by branches of the Hartz Mountains. The Blankenburg portion lies to the S.E. of the two former, between Prussia, Anhalt, and Hanover, and is traversed by the Hartz. Of the smaller portions some form *enclaves* in Hanover and others in Prussia.

Brunswick has an area of 1424 English square miles, and is divided into six circles, comprehending thirteen cities, and between four and five hundred smaller towns and villages. Besides the cities already mentioned the most important are Schöningen, Seesen, and Schöppenstedt. The population was in 1812, 209,527; in 1852, 271,208; in 1861, 281,708; and in 1871, 311,175. Of the last number 302,989 were Protestants, 7030 Roman Catholics, and 1171 Jews. The proportions in the political divisions were as follows:—

Circles.	Extent in square miles.	Inhabitants.		
		1861.	1867.	1871.
Brunswick	209	61,232	82,629	90,545
Wolfenbüttel	294	50,423	59,454	60,739
Helmstedt	304	41,155	52,023	53,705
Holzminden	221	41,290	42,129	41,551
Gandersheim	212	39,277	43,430	42,322
Blankenburg	184	19,855	22,925	22,523
	1424	253,232	302,792	311,715

Brunswick also possesses in Prussian Silesia the principality of Oels, which from 1647 to 1792 belonged to Würtemberg. A portion of the Hartz Mountains is common to Brunswick and Hanover, and is consequently known as the Communion-Hartz. Various minor arrangements have been made with Prussia for the more convenient organization of this district since the formation of the new German empire. The highest point of the mountains in the Brunswick territory is the Wormberg, 3230 feet in height. The principal rivers by which the duchy is watered are the Ocker, the Weser, the Aller, and the Leine. The lower parts of the country are generally fertile and well cultivated; the higher are mostly covered with forests of fir, oak, and beech. A very extensive improvement has been effected in the circle of Helmstedt by the draining of the *Drömling* swamp, and the rectification of the courses of the Aller and the Ohre. Of the whole duchy 32·7 per cent. is arable, 27·3 consists of meadow and pasture, and 31·8 is under wood. Agricultural and pastoral pursuits constitute the principal employment of the inhabitants; and the peasant class are usually well to do. The principal articles of cultivation are grain, potatoes, beetroot, flax, hops, and fruits. The growing of tobacco, which was formerly of great importance, is now very limited. In 1870 there were in the duchy 25,344 horses, 83,558 head of cattle, 386,757 sheep, 75,616 swine, 39,167 goats, 55,829 geese, and 8385 bee stocks. The mineral wealth of the country, which is chiefly derived from the Hartz Mountains, consists of copper, lead, iron, gold, silver, sulphur, coal, salt, and alum. In 1867 the total yield of coal was 219,400 tons, of iron ore 58,400, of pig-iron 143,000, of cast-iron 1584; the copper amounted to 383 tons; the lead to 710, and the vitriol to 1339. The manufactures, which are comparatively small, comprise (besides the preparation of the ores) spinning, weaving, and brewing. The principal iron-works are at Rübeland, Wieda, Delligsen, and Oker; and the chief centres of general industry are Brunswick and Schöningen. An active trade is carried on by means of the extensive railway communication with the rest of Germany.

The educational institutions comprise two ecclesiastical seminaries, an anatomical and surgical college, an architectural school at Holzminden, an agricultural school at Schöppenstedt, 5 gymnasiums, 25 burgher schools, and upwards of 400 village schools, besides several important establishments in the capital (see below). There is an extensive lunatic asylum at Königslutter, opened in 1865.

According to the constitution of 1832, which has been frequently modified, the Government is an hereditary monarchy, with a legislative assembly of representatives. These are chosen, by the law of 1851, twenty-one by those citizens who pay the largest amount of taxes, ten by the towns, three by the clergy, and a certain number by the communes. They hold office for six years, one-half going out triennially; and when they are not in session, they are represented by a standing committee of seven members. In the federal council the duchy has two votes, and it sends three deputies to the imperial diet. The ducal contingent, which still wears its famous black uniform, forms part of the 10th federal army corps. The state is the proprietor not only of a large proportion of the mines and forests in the duchy, but also of its railways. From these sources it derives a considerable part of its revenue, which in recent years has been augmented by the farming out of lotteries. By the budget for the period 1873–5, the annual receipts were fixed at 7,429,400 marks, or £371,470. The total debt, which had been mainly incurred for the formation of the railways, amounted to 65,400,000 marks, or £3,270,000.

The people of Brunswick are, with comparatively few exceptions, of Saxon race. The country people speak dialects of Low German, while High German is employed by the educated classes in the cities.

The more immediate ancestor of the house of Brunswick was Henry the Lion, who, in the 12th century, held the united duchies of Bavaria and Saxony; but having refused to aid the Emperor Frederick Barbarossa in his wars with the Pope, he was, by decree of the diet in 1180, deprived of both duchies, and only left the possession of his allodial domains of Brunswick and Lüneburg. His grandson, Otho, was invested in 1235 with these domains as a fief of the empire, and thus became the first duke of Brunswick. The two principalities which had been severed were united by Ernest the Confessor, but on his death in 1546, they were again divided between his two sons; the elder (or rather his son Augustus) receiving Brunswick-Wolfenbüttel, or Brunswick, and the younger Brunswick-Lüneburg, or Hanover. The ducal residence, which had before been at Wolfenbüttel, was in 1754 removed to Brunswick by Duke Charles. His successor, Duke Charles William Ferdinand, married Augusta, daughter of George III. of England He commanded the Prussian troops at Auerstädt in 1806, and soon after died of the wounds he had received in the battle. His possessions were immediately seized by Napoleon, and formed part of the kingdom of Westphalia till after the battle of Leipsic, when the duchy was restored to its rightful possessor, Frederick William, youngest son of the preceding duke. This prince fell at the head of his troops at Quatre Bras, and was succeeded by Charles Frederick, the elder of his two sons, who, being at that time a minor, was placed under the tutelage of George IV. of England, then prince-regent. The duke entered on the exercise of his authority in October 1823, but in consequence of a revolution in 1830 was obliged to abdicate in 1831 in favour of his brother William, the present duke. During the long reign of duke William many important changes have taken place in the internal organization of the duchy, and most of them have been in the direction of greater civil liberty. Of great moment was the establishment of a new criminal code in 1840; and publicity of parliamentary discussion, the freedom of the press, the introduction of jury-trials in criminal cases, and the legitimation of Christian-Jewish marriages were secured in 1849. In 1851 military service was recognized as binding on all, and the election of members of parliament was placed more directly in the hands of the people. In 1864 the *Stolgebühren*, or taxes paid to the established clergy on the occasion of a baptism, a marriage, or a burial, were made no longer leviable on Jews, Roman Catholics, or other dissenters. The introduction of the German commercial code was effected in 1864, and freedom of trade was introduced in the same year. Treaties of mutual inheritance exist between the houses of Hanover and Brunswick; and should the present duke, who is still unmarried, die without issue, the duchy will pass to the house of Hanover. The ex-duke, to whose sons the right would first have descended, died childless at Geneva in August 1873. He had spent his life in pitiable devotion to certain hobbies, the most remarkable of which was the collection of valuable diamonds. His various treasures were bequeathed to the city of Geneva, but the will is disputed by the present duke.

Brunswick, the capital of the above duchy, is situated on the Ocker, 37 miles E.S.E. of Hanover by rail, and 52 W.N.W. of Magdeburg, in 52° 16′ N. lat. and 10° 32′ E. long. In spite of the numerous alterations effected during the present century, the city is still of an antiquated appearance, and is for the most part contained within the limits of its old fortifications. These, which were dismantled in 1797, have given place to a regular circle of gardens and promenades, which rank among the finest in Germany.

The ducal palace is a handsome modern structure, erected since 1865, when the most of the previous building, which only dated from 1831, was destroyed by fire. The famous Quadriga of Rietschel, which perished at the same time, has been replaced by a copy by Howald. Among the ten or twelve churches in the town the most important are the cathedral of St Blaise, built by Henry the Lion in 1173; St Magnus's, which is the oldest, dating from 1031; St Andreas, with a spire 318 feet high; and St Catherine's, a building of the 13th century. The educational and charitable institutions of Brunswick are numerous and important. Of the former may be mentioned the *Collegium Carolinum*, founded in 1745, the great United Gymnasiums (which include the former commercial gymnasium, the Martineum, and the Catherineum), the Medico-Chirurgical College, and the Academy of Forestry; while among the latter are a deaf and dumb institution, a blind asylum, an orphanage, and various hospitals and infirmaries. There are also two public libraries, a museum, a theatre, and several scientific societies. A monument, 60 feet high, to Duke Frederick William, who was slain at Quatre Bras, gives its name to Monuments-Platz, and another to the S.E. of the town perpetuates the memory of Schill and his companions. The trade of Brunswick, formerly restricted by obsolete legislation, is gradually increasing. The principal articles of manufacture are coarse cloth and leather; and, to a smaller extent, gloves, papier-maché, and paper wares. The town has long been famous for a special kind of beer, called Mumme, from the name of the Brunswick brewer who invented it in 1492. In 1867 the population amounted to 50,369, inhabiting 3487 houses, and divided into 10,850 families. In 1871 it had increased to 57,883.

Brunswick is said to have been founded about 861 by Bruno, duke of Saxony, from whom it was named *Brunonis Vicus*. Afterwards enlarged and fortified by Henry the Lion, it became one of the most important cities of Northern Germany. For a long time its constitution was rather peculiar, as it consisted of five separate townlets, each with its own walls and gates, its own council and Rathhaus,—a condition of which traces are still evident. In the 13th century it ranked among the first cities of the Hanseatic league, but it never succeeded in obtaining imperial freedom. After this, however, it declined, in consequence of the many divisions of territory among the branches of the reigning house, the jealousy of the neighbouring states, the Thirty Years' War, and more recently the French occupation. In 1830 it was the scene of a violent revolution, which led to the removal of the reigning duke.

BRUNSWICK, a town of the United States of America, in Cumberland County, Maine, 27 miles N.N.E. of Portland, on the right bank of the Androscoggin River, which, with a fall of about 50 feet in half-a-mile, supplies a large amount of water-power. Numerous industrial establishments have been erected, the most important being a cotton factory, flour-mills, and bleach-works. The lumber-trade, which was formerly of great extent, has been in great measure replaced by the building and owning of ships. Besides possessing an excellent system of graduated schools, Brunswick is the seat of Bowdoin College, founded in 1802, and of the Maine Medical School, which dates from 1820. The river is crossed by two bridges, one of which unites the town with Topsham, and the other belongs to the Kennebec and Portland railway. Population in 1850, 4927; in 1870, 4687, or including the neighbouring village, 6136.

BRUNTON, MRS MARY (1778-1818), a novelist of the early part of the 19th century, was born on the 1st November 1778, in the island of Barra, Orkney. Her father, Colonel Balfour, was a man of importance in the island, and she received a very careful and excellent education. At the age of twenty she married the Rev. Mr Brunton, minister of Bolton in Haddingtonshire, who in 1803 received a call to a church in Edinburgh. In 1811 Mrs Brunton published anonymously her first novel, *Self-Control*. It at once became very popular; the first edition was sold off in a month, and a second and third q... followed. The book was especially recommended by high moral and religious tone; it was a novel with purpose. As a work of art, it cannot take a high p... the plot is extravagant and improbable, and the charact... have none of the charm of reality about them. The sto... is constructed after the model of *Clarissa*, and contains ... usual virtuous heroine and vicious hero, with an unu... number of abductions and mysteries. Her second n... *Discipline*, was published in 1814, and was received wi... equal favour. Mrs Brunton died on the 19th Decemb... 1818. An unfinished tale, *Emmeline*, was published afte... her death by her husband, with a notice of her life.

BRUSHES AND BROOMS are implements composed of a solid basis in which a tuft or tufts of hair or of vegetable or other fibres are secured. They are mentioned by various ancient writers, as Homer, Sophocles, and Euripides. Perhaps the earliest notice is the figurative "besom of destruction" (Isa. xiv. 23). Brushes are of two kinds, simple and compound. The former consist of but one tuft, as hair pencils and painters' tools. The latter have more than one tuft. Brushes with the tufts placed side by side on flat boards, as plasterers' brushes, are called stock-brushes. The single tuft brushes, or pencils for artists, are made of the hair of the camel, badger, goat, and other animals for the smaller kind, and pig's bristles for the larger. The hairs for pencils are carefully arranged so as to form a point in the centre, and, when tied together, are passed into the wide end of the quill or metal tube and drawn out at the other end to the extent required. The small ends of the quills having been previously moistened, in drying contract and bind the hair. A similar effect is produced with metal tubes by compression. Compound brushes are—first, set or pan-work; second, drawn-work. Of the former, an example is the common house-broom, into the stock of which holes are drilled of the size wanted. The necessary quantity of bristles, hair, or fibre, to fill each hole is collected together, struck on the working bench at the thick ends, dipped into molten cement chiefly composed of pitch, bound round with thread, dipped again, and then set into a hole of the stock with a peculiar twisting motion only to be acquired by practice. In drawn-brushes, of which those for shoes, teeth, nails, and clothes are examples, the holes are more neatly bored, and have smaller ones at the top communicating with the back of the brush, through which a bight or loop of wire passes from the back of the stock. Half the number of hairs or fibres needed for the tufts to fill the holes are passed into the bight of the wire, which is then pulled smartly so as to double the hairs and force them into the loop-hole as far as possible. With all brushes, when the holes have been properly filled, the ends of the fibres outside are cut with shears, either to an even length or such form as may be desired. The backs are then covered with veneer or other material to conceal the wire and other crudities of the work. A process called trepanning is adopted with some small brushes. The drawholes come out at some inconspicuous part of the stock, and the hairs or fibres having been properly secured, the holes are plugged up in order to conceal them as much as possible.

The bristles used in this manufacture are imported chiefly from Russia and Poland, and are sorted into black, grey, yellow, white, and lilies. They vary in length, and are separated by the workman striking a quantity held in the hand smartly on a bench, the thick ends downwards. He then applies them to a gauge to ascertain the lengths of those that project, and, seizing them between his finger and thumb, draws them out of the bundle and places them with those of corresponding dimensions. They are sorted according to thickness by a process called "dragging,"

which consists in passing them through a kind of comb, which retains those that are too stout to go between the teeth. By repeating this with finer combs the bristles can be assorted to any number of sizes required. Various other substances are now used in place of bristles, and this was greatly stimulated by the scarcity of these during the Russian war. In 1808 whalebone fibres were patented in England for the purpose, and in 1810 twigs of broom, mallow, rushes, and other shrubs and plants. In 1842 the shafts of quills prepared and split up, and in 1872 horn and similar substances were used in the same way. The latter are softened by steeping them in an infusion of sage leaves or plants of that class, then flattened, rolled out, and extended and moulded so as to disintegrate them into threads. In 1844 a brush was patented made of stiff fibre and bristles, hard in one part and soft in another, so that the softer parts should follow the harder, and take up what the latter left. The same inventor also made tooth-brushes on the same principle. The hairs of the squirrel, horse, badger, bear, and other animals are also used for brushes, and those from the ears of cows and from the ichneumon, amongst others, for artists' pencils. When necessary the bristles are bleached by sulphur or other chemical agents. In the United States a kind of sorghum or broom-corn is extensively cultivated for the manufacture of brooms, and especially by the Shakers of New York State. The seed of the crop alone, it is stated, often pays the expense of cultivation, being, when mixed with other corn, good food for cattle and horses.

One of the most important purposes to which brushes have been applied is that of sweeping chimneys. So far back as 1789 John Elin patented an arrangement of brushes with this purpose in view. He was followed at intervals by others, and the use of these machines having been found practicable, the Acts 3 and 4 Vict. c. 85, and 27 and 28 Vict. c. 37, put an end to the cruelties previously practised, prohibiting the employment of children in sweeping chimneys.

Revolving brushes for cleaning rooms were patented in 1811, and others have followed. In 1825 they were constructed to take the place of teazles for raising the wool or pile of woollen and other cloths, and they are now used for polishing and other purposes in various manufactures. The first patent in which they were applied to hair-dressing appears in 1862. The patented invention for sweeping and cleaning roads by means of revolving brushes and other contrivances are very numerous. The first appears in 1699. It is that of Edmund Henning for "a new engine for sweeping the streets of London, or any city or town." No specification was enrolled, but the invention included the loading and removal of the refuse "with great ease and quickness." A long interval elapsed before anything further was done in this direction, the next patent being that of W. Ranyard, on 1st November 1825, which consisted of a number of brushes mounted upon two rims or placed upon an axis, which was raised on a vehicle or barrow. Boase and Smith's followed in 1828, including scraping, sweeping, and watering. From 1836 a succession of inventors follow each other rapidly, amongst whom frequently appears "Joseph Whitworth." Some of the most recent patents are Greenwood's, 17th February 1873; Robinson's, 4th April 1874; Sinclair and Clayton's, 20th February 1875; Kitson's, 21st April 1875. Many of these inventions include the removal of the refuse, as well as scraping. Some propose watering in addition; but the simplest and most easily managed is that most commonly used, which scrapes or sweeps the mud and rubbish to the sides of the road. A particular point in Mr Kitson's invention seems to be to clear out the dust and mud from between the joints of the paving stones.

An improvement in brushmaking was patented in 1830 by Timothy Mason, which consisted in cutting grooves in the stocks or bases of brushes instead of boring holes, the grooves increasing in width from the outer surface. The hairs or bristles are tied up into tufts or knots, dipped in cement, placed in the grooves, and wedged tightly by the use of a blunt tool, which operation causes the tufts to expand and hold firmly in the enlarged recess. Various contrivances have been patented by which brushes might be self-supplied with water, soap, paste, paint, and the like, when in use, by means of receptacles or pipes being attached to them for the purpose.

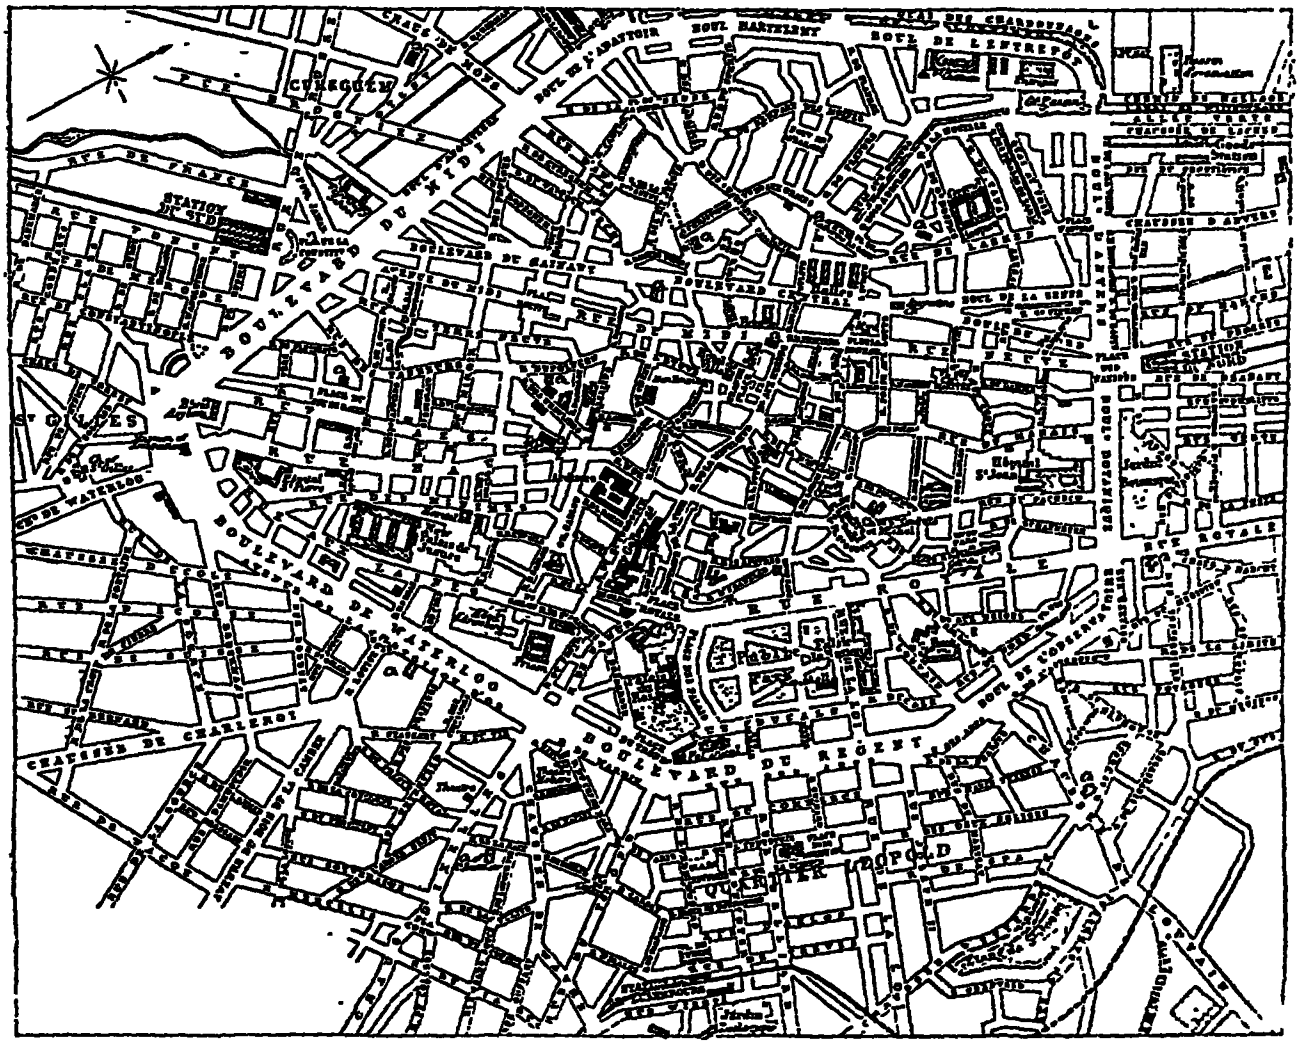
One of the greatest advances in the brushmaking of the present day is the Woodbury machine, an American invention for bunching, wiring, and inserting bristles in the stock. In this machine a metal comb of uniform thickness is filled with bristles, holding them by the middle, so that one-half of the bristles appear above the surface of the comb, the other underneath. The comb thus charged moves in guideways, and discharges the bristles from each division successively into a channel in which, by an ingenious contrivance, they are brought gradually into a horizontal position and a proper quantity taken up to form a tuft, which is moved along an incline. At the bottom of this is a hollow cylinder that does not enter, but is placed firmly against the tuft hole in the brush stock. A plunger now acts upon the bristles. The end of the plunger is slotted crossways; one slot receives the bristles, the other a piece of wire. The plunger is made to descend and double the bristles into a loop at the middle. Other mechanism unwinds the binding wire from a reel, straightens the wire, and passes the proper quantity through the enlarged upper portion of the slot, and at the same time cuts off the length required. The plunger now descends further, receiving a rotatory motion on its vertical axis, winds the wire by forcing it into the thread of a nut at the lower portion of the cylinder, and fastens it round the double end of the bunch. The end of the wire now acts as a tap, cutting a female screw in the end of the block, whilst the upper end of the wire thread, by expanding, acts as a pawl, and prevents the unscrewing of the tuft. This machine is described in the *Scientific American*, 1872, p. 31, with illustrations.

For further information on the subject of brushes, the reader will find the abridgement of specifications relating to brushing and sweeping, published at the Patent Office, a most useful manual. (J. J. L.)

BRUSSELS (French, *Bruxelles*; Flemish, *Brussel*; German, *Brüssel*), capital of Belgium and of the province of South Brabant, is situated on the small River Senne, about 50 miles from the sea, in 50° 51′ N. lat., 4° 22′ E. long. It lies in the midst of a beautiful and fertile country, and is picturesquely built on the top and sides of a hill, which slopes down to the Senne. The general contour of the old town of Brussels is pentagonal, and is well defined by the boulevards, which occupy the site of the old fortifications; but extensive additions have been made, especially to the east and south, and present a very irregular outline

Brussels may be considered to consist of two parts, each presenting characteristics peculiar to itself. The New Town or upper part of the city is dry and healthy, and contains a very large number of handsome buildings, both public and private. The lower part is the more ancient and interesting of the two, but is damp, and in summer unhealthy, from the exhalations of the river and the numerous canals. In the former are situated nearly all the public offices, the royal palace, the chamber of deputies, the residence of the foreign representatives, and the principal hotels. The latter contains the Hôtel de Ville, and

some of the best remains of the old Gothic architecture, and is the seat of nearly all the trade and commerce of the town. The facilities for commerce are very considerable. Though the Senne is not navigable itself, and is in fact now (1876) in process of being arched over to afford room for a new boulevard, it supplies water to some of the canals that intersect the lower portion of the city. By these canals Brussels communicates with the great Belgian cities, Mechlin, Ghent, Bruges, and Antwerp on the north, and Charleroi on the south. It further enjoys the advantage of railway communication with France and Germany, and the chief towns of the Belgian dominions. The streets are for the most part well paved, well lighted, and abundantly supplied with excellent water. There are in the town innumerable fountains, some of w' : h handsomely ornamented with sculptures in stone bronze. Of these the best are *Les Fontaines des Fleu.* the Hôtel de Ville, *La Fontaine de Minerve* in one c great squares, and the *Mannekin-pis* behind the Hôt Ville. Some of the streets are macadamized, but majority of them are causewayed, while the *trottoirs* either flagged or paved with flint-stones. In the new some of the streets are remarkably handsome; they con a considerable number of shops and cafés similar to t of Paris, and form the chief promenades of the tants. In the old town they are for the most part na and sombre. There are fourteen squares in B many of which are used as market-places. Of these



Plan of Brussels.

largest are the Place du Grand Sablon, the Place Royale, and the Grande Place before the Hôtel de Ville. In the last-named square, surrounded for the most part with houses that date from the time of the Spanish possession, the Counts Egmont and Horn were beheaded in 1568, by order of the duke of Alva, who surveyed the scene from the windows of the Brood-Huys (otherwise Maison du Roi), a remarkable specimen of Gothic architecture still extant. In the Place de la Monnaie are the mint, the exchange, and the great theatre. In the Place des Martyrs, the heroes who fell in the Revolution of 1830 are interred. In front of the palace is the Public Park, a fashionable summer promenade, which covers an area of about 14 acres. It is beautifully laid out with walks, adorned at moderate distances with groups of sculpture; and as it is planted with trees which shade it from the sun, the grass is always fresh and green. In the lower town is the Allée Verte, an equally fashionable promenade, which runs parallel with the Mechlin canal, having a triple row of linden trees on each side, and leads towards the village of Lacken, where, since 1815, the king has had a suburban castle.

Of the public buildings of Brussels the most remarkable are the cathedral church of St Michel et Ste Gudule, the Hôtel de Ville, and the Palace of Justice, a modern erection. The cathedral was built in 1010, and in it was held the first chapter of the order of the Golden Fleece in 15?5 It contains a remarkable pulpit, and some splendid specimens of stained glass. From its towers a fine view of the surrounding country may be obtained. The Hôtel de Ville, built in 1400, is profusely ornamented; it has a tower 360 feet in height. The other public buildings of Brussels are for the most part handsome, but are quite

uninteresting. The principal hospitals are those of St Peter and St John, which are both admirably managed, and contain together about 1000 beds. The patients are waited upon by the sisters of charity. As in all the large Belgian towns, there is, besides two other nunneries, a convent of Beguins, which formerly numbered 1000 nuns. The mass of the native population are Catholics; but as the English residents are very numerous, there are several Protestant churches. The Jews have a synagogue at Brussels, and hold their grand consistory there.

The number of charities in Brussels is very great; of these the most important are the Foundling Hospital, the Orphan Asylum, and the Société Philanthropique, whose object is to prevent mendicity. There are besides numerous alms-houses, which annually give relief to about 35,000 persons. Some of these establishments are supported entirely by subscription; others of them are subsidized by Government. Great attention is paid to the education of poor children. The communal expense for public instruction amounted in 1873 to 858,150 francs. Among the educational establishments are the gymnasium, the polytechnic school, the Royal Athenæum, a Lancasterian school, and many public and private academies, besides the Free University, which was founded in 1834 by a company belonging to the liberal party. The number of students at the university amounted in 1874 to nearly 580; while at the Royal Athenæum the number in the same year was 772. There is also a well-conducted veterinary and agricultural school.

Some of the societies of Brussels are very celebrated. The Royal Conservatorium of Music had 529 pupils on its roll in 1874. The Royal Society was founded in 1769. The geographical establishment of Vandermaelen, instituted in 1830, is in a flourishing condition. The botanical garden is one of the best in Europe, and there is also a large zoological garden. The Palais de l'Industrie contains an admirable museum of natural history, and an extensive and valuable collection of books and manuscripts, which is accessible to the public. The number of books is 234,000, of which 2000 belong to the 15th century, while the manuscript department, known as the *Bibliothèque de Bourgogne*, contains about 22,000 MSS., many of which are beautifully illuminated. From sixty to sixty-five thousand francs are annually voted for the maintenance of the library. Eminent literary men and others are sometimes allowed to take books home, but the number to whom this privilege is conceded never exceeds 100 annually. There are numerous printing and lithographic presses in constant operation in Brussels, a large number of the former being engaged in the republication of standard works that appear in France.

The principal manufactures of Brussels are those of lace and tulle, carpets, woollen, linen, and cotton fabrics, jewellery, and articles of vertu. The most remarkable of these is that of lace. The finer sorts of flax used in the manufacture cost from £12 to £16 sterling per lb. An English yard of this lace costs £8. The persons who spin the thread work in rooms almost completely darkened, and are thus compelled to concentrate their attention; and the thread spun in this way is said to be finer and more delicate than any that has hitherto been produced by other means. Excellent carriages are made in Brussels two-thirds cheaper than those of England, but inferior to them in quality.

In 1837, the population of Brussels was 104,265; in 1846, 123,874; in 1849, 138,189; in 1850, 142,289; and in 1873, 180,172. At the last date there were 365,404 in the nine contiguous communes. In 1846, the houses in the town numbered 13,563, and in 1866, 18,543.

The history of Brussels, though it does not date from so remote a period as that of other Flemish cities, can still be clearly traced back to the 7th century. At that time St Gery, bishop of Cambray, built a chapel on one of the small islands in the river, and by his eloquence and piety soon attracted a large congregation. The site being well adapted for building, a hamlet soon sprung up, and speedily became a town, which in the 11th century was walled in and fortified. Though in commercial importance Brussels did not at this time equal Ghent or Bruges, its traffic in cloth was very considerable, and its workers in iron and steel were not surpassed by any in Europe. In the 14th century the various trades were incorporated into guilds, who regulated the taxes and other financial matters of the city, and drew up a code of municipal laws, in which the principle of trial by jury was admitted. These arrangements had scarcely been completed, when a dreadful fire visited the city and nearly burnt it to the ground. At the end of this century a general persecution of the Jews in Europe took place. In Brussels, many of them were put to death, and the value of the confiscated property amounted to upwards of half a million sterling. At the beginning of the 15th century, Brussels was again visited by a destructive fire, from the effects of which it speedily recovered by the patriotic exertions of its rulers, and soon became more distinguished than ever as a seat of learning, art, and science. In 1489, and again in 1587, it was visited by the plague, which, on the former of these occasions, carried off many thousands of the inhabitants. Its horrors were enhanced by the ensuing famine, which lasted for four years.

Brussels was highly favoured by Charles V., who often resided in the city, and raised it to the rank of capital of the Netherlands. Under his son Philip II. it became the centre of the great revolutionary movement, which resulted in the independence of the United Province. In 1598 Brussels passed into the dominion of the Austrians, and soon began once more to prosper. In 1695 the French under Marshal Villeroy besieged Brussels, but were obliged to retire after doing much damage to the town; and in 1706 the city opened its gates to Marlborough. In 1746 it was again besieged by the French under Marshal Saxe, and after a siege of three weeks was obliged to surrender. In 1792 it fell into the hands of General Dumouriez, who being soon after defeated at Louvain, evacuated Brussels for a while, but again entered it in 1794. From that year till 1814, it remained in the possession of the French, as capital of the department of the Dyle. On the fall of Napoleon, Belgium and Holland were united into one kingdom under William of Nassau, and Brussels was the seat of government alternately with the Hague. In 1830, however, after a sanguinary conflict of four days in the streets of the city, the Belgians declared their independence; and erecting their state into a separate kingdom, offered the crown to Leopold of Saxe-Coburg, whose long and peaceful reign (1831–1865) contributed greatly to the development of the resources of the country.

BRUTON, a market-town of England, in the county of Somerset, pleasantly situated in the valley of the Brue, about 10 miles S.S.W of Frome by rail. It has a town-hall, a hexagonal market-cross, a grammar school, and some manufactures of hair-cloth, woollens, and hosiery. Population of hundred in 1871, 3701.

BRUTUS. The name of a distinguished plebeian family at Rome. The first who bore it was LUCIUS JUNIUS BRUTUS, one of the first two consuls, 509 B.C. According to the legends, his mother was the sister of Tarquinius "Superbus," the last of the Roman kings, and at his father's death, his elder brother had been put to death by the reigning family in order to get possession of his wealth. Junius, the younger, owed his safety to his reputed

dulness of intellect (whence his surname of Brutus), which character, however, he had assumed with a view both to his present security and future revenge. The opportunity came when Lucretia, wife of Collatinus, was outraged by Sextus Tarquinius; and he took a leading part, together with her husband and father, in expelling the family of the Tarquinii from Rome. He and Collatinus were therefore elected consuls,—or rather prætors, which was the original title. In a conspiracy formed afterwards for the restoration of the banished dynasty, the two sons of Brutus were found to be deeply implicated, and were executed by sentence of their father, and in his sight. The Etruscans of the cities of Veii and Tarquinii making an attempt to restore Tarquinius to the throne, a battle took place between them and the Romans, in which Junius Brutus engaged Aruns, son of the deposed king, in single combat on horseback, and both fell by each other's hands. The Roman matrons are said to have mourned a year for him, as "the avenger of woman's honour," and a statue was erected to him on the Capitol.

Many members of the family rose to eminence in the Republic, and are found, as plebeians, ranged on the popular side. The most distinguished of these was Decius Junius Brutus, consul, 325 B.C.

In later times came Marcus Junius Brutus, a jurist of high authority, considered as one of the founders of Roman civil law, to whom Cicero dedicates his treatise called *Orator*. His son, of the same name, made a great reputation at the Roman bar, chiefly by undertaking prosecutions, and from the vehemence and bitterness of his speeches became known as "the Accuser."

Decius Junius Brutus first served under Julius Cæsar in Gaul, and afterwards commanded his fleet, and was held by him in great honour and esteem. Nevertheless, whether from patriotism or from lower motives, he joined in the conspiracy against his patron, and, like his relative Marcus Junius Brutus, was one of his assassins. He afterwards resisted the attempt of Antony to obtain absolute power; and after heading the republican armies against him for some time with success, was deserted by his soldiers in Gaul, betrayed by one of the native chiefs, and put to death by order of Antony, 43 B.C.

Best known of all is Marcus Junius Brutus, son of a father of the same name (treacherously put to death by order of Pompey during the civil wars), and of Servilia, sister of Cato of Utica. Young Marcus was only eight years old at his father's death, and was educated with great care by his mother and uncles. He at first practised as an advocate. In spite of his father's fate, he at first supported the cause of Pompey against Cæsar, but was pardoned by the latter after the victory of Pharsalia, and subsequently appointed by him to the government of Cisalpine Gaul. His justice and moderation won him great honour from the provincials under his rule. Influenced probably by his friend Caius Cassius, he afterwards joined in the conspiracy against the great dictator, and was one of the foremost in his assassination. He maintained the cause of the republic by seizing and holding against Antony's forces the province of Macedonia, where he was joined by Cassius. But at Philippi they were defeated by Antony and Octavianus Cæsar, and rather than be taken prisoner, he fell on his sword, 42 B.C. He was an earnest student through all his active life, and is said to have been employed in his tent, on the night before the battle of Pharsalia, in making an abridgment of Pausanias.[1] He wrote several philosophical treatises and some poetry, but nothing has survived. He combined with these tastes the incongruous occupation of a money-lender, Cicero and King Ariobarzanes being amongst his clients. His second wife was his cousin Portia, daughter of Cato.

[1] "Is not the leaf turned down
Where I left reading?"
Shaksp. *Jul. Cæsar*, Act iv. sc. 3.

BRUTUS, or Brute, is asserted in the fabulous history of Geoffrey of Monmouth to have been the grandson of Æneas, and to have destroyed the race of giants in Britain, to which he gave his name, founding there the city of New Troy, afterwards London.

BRÜX, a city in the circle of Saatz, in the Austrian kingdom of Bohemia, on the River Bila. It consists of an old town, surrounded with walls, and three suburbs, and contains, besides the courts and public offices of the circle, nine churches, three monasteries, a gymnasium, barracks, a military college, and an educational establishment of Piarists. Its inhabitants are partly engaged in the coal-mines, and in the preparation of salts from the Seidlitz waters in the vicinity. A battle was fought here in 1421 between the Hussites and Saxons; and in 1646 the Swedes captured the fort of Landswert, now dismantled. Population in 1869 (including Taschenberg), 6102.

BRUYÈRE, Jean de la. See La Bruyère.

BRYANT, Jacob (1715-1804), a writer on theological and mythological subjects, was born at Plymouth in 1715. His father had a place in the customs there, and was afterwards stationed in Kent, where his son was first sent to a provincial school, whence he was removed to Eton. Here he appears to have remained till 1736, the date of his election to King's College, Cambridge, where he took his degrees of bachelor and master of arts in 1740 and 1744. He returned to Eton in the capacity of private tutor to the duke of Marlborough, then marquis of Blandford; and the good taste which his pupil showed through life, in the protection of the fine arts, and in the pursuit of science, sufficiently demonstrated the beneficial influence of his instructor's example. In 1756 he went to the Continent as private secretary to the duke of Marlborough, then master-general of the ordnance and commander-in-chief of the forces in Germany; and he was rewarded after his return, for his various services to the family, by a lucrative appointment in the ordnance, which allowed him ample leisure to indulge his literary tastes. Bryant died in his eighty-ninth year, on the 14th November 1804, in consequence of a fall from his chair while reaching up for a book in his library. He left his library to King's College, having, however, previously made some valuable presents out of it to the king and to the duke of Marlborough. He bequeathed £2000 to the Society for the Propagation of the Gospel, and £1000 for the use of the superannuated collegers of Eton School.

His principal works are the *New System or Analysis of Ancient Mythology, wherein an attempt is made to divest tradition of fable, and to reduce truth to its original purity*, 3 vols. 4to, 1774-76, which is fantastic and now wholly valueless; *An Address to Dr Priestley on the Doctrine of Philosophical Necessity*, 8vo, 1780; *Vindiciæ Flavianæ; Observations on the Poems of Thomas Rowley, in which the authenticity of these poems is ascertained*, 2 vols. 12mo, 1781; *Treatise on the Authenticity of the Scriptures, and the Truth of the Christian Religion*, 1792; *Observations upon the Plagues inflicted upon the Egyptians*, 8vo, 1794; *Observations on a Treatise, entitled Description of the Plain of Troy, by Mr de Chevalier*, 4to, 1795; *A Dissertation concerning the War of Troy, and the expedition of the Greeks, as described by Homer, showing that no such expedition was ever undertaken, and that no such city in Phrygia existed*, 4to, 1796; *Observations on the Vindication of Homer, written by J. B. S. Morritt, Esq.*, 4to, 1799; *The Sentiments of Philo Judæus concerning the Word of God*, 8vo, 1797; *Dissertations on various Subjects in the Old Testament*.

BRYAXIS, a Greek sculptor, the contemporary of Scopas and Praxiteles, with whom he took part in the sculptures of the mausoleum at Halicarnassus, about 345 B.C. Of his other works the following are mentioned:—five colossal figures of gods at Rhodes, Bacchus (*Liber Pater*) at Cnidus, a group of Æsculapius and Hygeia at Megara, Apollo in the grove of Daphne at Antioch, a statue of Pasiphaë, and

a portrait of Seleucus (it is not said which). On doubtful authority he is also said to have been the sculptor of a group of Jupiter and Apollo with a lion at Patara, and of a statue of Serapis. Before his time there is no mention of statues of Æsculapius or Serapis, and it is supposed that the types which we now have of these deities were introduced by Bryaxis. The statue of Apollo at Daphne represented the god in his character of Musagetes, with long flowing drapery girt at the waist. The Bacchus at Cnidus must have been similarly draped; and altogether Bryaxis seems to have shown as much preference for draped and mature forms as Praxiteles displayed for nude and youthful figures.

BRYDGES, Sir Samuel Egerton (1762–1837), a miscellaneous writer, was born 30th November 1762. He studied at Queen's College, Cambridge, and adopted the profession of law. In 1790 he persuaded his elder brother that their family were the heirs to the barony of Chandos, being descended from a younger branch of the Brydges who first held the title The case was tried and lost, but Brydges never gave up his claim, and used to sign himself *Per legem terræ* B. C. of S. (*i.e.* Baron Chandos of Sudeley). It has been said that he underwent the labour of re-editing Collins's *Peerage*, for the sole purpose of inserting a statement about his supposed right. In 1814 he was made a baronet, and in 1818 he left England. He died at Geneva in 1837. Sir Egerton was a most prolific author; he is said to have written 2000 sonnets in one year. His first volume of poems was published in 1785; of his other numerous works, including novels, political pamphlets, and bibliographies, perhaps the most important are *Censurà Literaria*, 10 vols., 1805–9, and *Autobiography, Times, Opinions, and Contemporaries of Sir S. E. Brydges*, 1834.

BRZEZANY, a town of Austria, in Galicia, S.E. from Lembergo n the River Zlota-Lipa, in 49° 30′ 25″ N. lat. and 24° 41′ 39″ long. It possesses a Roman Catholic, a Greek, and an Armenian church, a castle, a convent, and a gymnasium; and it carries on a considerable manufacture of linen and leather. The population in 1869, including some contiguous villages, amounted to 9290.

BUBASTIS, the great name of the Egyptian goddess Bast, supposed to hold the same place in the Egyptian Pantheon as Artemis or Diana. The triad of Memphis consisted of three gods—Ptah or Vulcan, the Greek Hephaistos; Bast, the wife of Ptah and mother by him of Nefer-Atum, or "the good Tum;" and Sexet, formerly called Pasht, the sister or antithesis of Bast. This last goddess was also called *Merienptah*, or "the beloved of Ptah." Although the names of Bast, Sexet, and Merienptah are written with different hieroglyphs, their types are exactly alike, being that of a lion-headed goddess having on her head the sun's disk entwined by an uræus. Sexet and Bast appear both to have personified fire acted upon by Ptah, the cosmic demiurgos, and Vulcan. Owing to the pantheistic ideas prevalent in Egypt, Bast was identified at times with Neith, the Egyptian Athene or Minerva, and Athor, the Aphrodite or Venus. Her type and attributes were also those of Tefnu or Daphne, the pupil or daughter of the sun; and it was probably from her relation to this goddess, who, with her twin brother Su or Sôs, represented the Apollo and Artemis of the religious, and the Gemini, or Twins, of the zodiacal system, that Bast was identified with Diana. Bast was supposed to be the beneficent portion of the element fire and the bringer of good fortune; her sister and rival Sexet to represent the malevolent deity of the element and the bringer of ill-fortune. At a later period Bast has the head of a cat substituted for that of a lion, and holds in her hands a vase or situlus. About the time of the 26th dynasty, figures of her, made of porcelain, abound, representing the goddess seated and sometimes holding a sistrum. Her local worship was principally carried on at Bubastis, the modern Tel-Basta. The Speos Artemidos, or Sheik Hassan, Anxtata supposed to be Letopolis near Memphis. The cat was sacred to this goddess, and mummies of this animal are found at Bubastis, the Speos Artemidos, and Thebes, sometimes in bronze or wooden figures in shape of the cat seated on a pedestal, carved in form of the vase which was the hieroglyphic name of the goddess. Connected with Bubastis were the Bubasteia or festival of the goddess, celebrated with great pomp at the city of Bubastus, and the largest and most important in Egypt. The Egyptians flocked to it by water, accompanied by music; and as many as 700,000 are said to have been present on the occasion. A nome was also named after this goddess, and the capital city called Bubastus or Bubastis was on the site of the present Tel Basta on the Bubastite branch of the Nile. In later times the canal of Necho started from it to the Red Sea, and the adjoining lands were given by Psammetichus to the Greek mercenaries. It is, however, mentioned in inscriptions of the earlier periods of history, and was an important city. Taken by the Persians under Memnon, its walls were razed, and it sunk gradually in importance. The nome struck some bronze coins of small size in the eleventh year of the Emperor Hadrian, 127 A.D., with a goddess holding in her hands a small animal, possibly a cat. Many antiquities and remains are found in the ruins of the city.

BUCCANEERS, a band of piratical adventurers of different nationalities united in their opposition to Spain, who maintained themselves chiefly in the Caribbean Seas during the 17th century.

The island of St Domingo was one of several in the West Indies which had early in the 16th century been almost depopulated by the oppressive colonial policy of Spain. Along its coast there were several isolated establishments presided over by Spaniards, who were deprived of a free and convenient market for the produce of the soil by means of the monopolies imposed by the mother country. Accordingly English, Dutch, and French vessels were welcomed with eagerness, and their cargoes readily bought. The island, thinned of its former inhabitants, had become the home of immense herds of wild cattle, which multiplied with great rapidity; and it became the habit of the hardy smuggler to provision his ship at St Domingo. The natives still left upon the island were skilled in preserving flesh by means of fire and smoke at their little establishments called Boucans. The adventurers learned "boucanning" from the natives; and gradually Hispaniola became the scene of an extensive and illicit butcher trade. A sailor in those days when piracy abounded was expert with his weapons, and was almost a fighting man by trade. Spanish monopolies were the pest of every port from Mexico to Cape Horn; and the seamen who had sailed the Caribbean were filled with a natural hate of everything Spanish. The pleasures of a roving life gained upon them, while the monotony of its routine was broken by occasional skirmishes with the forces organized and led by Spanish officials. Out of such conditions arose the Buccaneer, alternately sailor and hunter, even occasionally a planter,—roving, bold, not overscrupulous, not unfrequently savage, with an intense detestation of the power and the representatives of Spain.

In the year 1625 indirect assistance and encouragement previously given culminated in a combined venture on behalf of the Buccaneers by the Governments of England and France. Each nation contributed a band of colonists, and selected the island of St Christopher, in the West

Indies, where the settlers of both nations were simultaneously planted. The English and French were, however, not over-friendly; and in 1629, after the retirement of several of the former to an adjoining island, the remaining colonists were surprised and partly dispersed by the arrival of a Spanish fleet of thirty-nine sail. Many were carried off, and threats were freely used as to the future settlement of the island. But on the departure of the fleet the scattered bands returned, and encouragement was given to their countrymen in St Domingo. For buccaneering had now become a most profitable employment, operations were extended, and a storehouse secure from the attacks of the Spaniards was required. The small island of Tortuga lying to the N.W. of Hispaniola was seized for this purpose in 1630, converted into a magazine for the goods of the rivals, and made their headquarters, St Domingo itself still continuing their lucrative hunting ground.

Spain was not indifferent to this proceeding, though she could not prudently take immediate action. Eight years, however, had not gone, ere, watching her opportunity when many Buccaneers were absent in the larger island on their ordinary pursuit, she attacked Tortuga, and massacred every settler she could seize. But the hunters to the number of 300 returned; and the Buccaneers, now distinctly seen to be in open hostility to the Spanish arms, began to receive recruits from every European trading nation, and for three-quarters of a century became the acknowledged scourge of the Spanish American trade and dominions.

France, throughout all this, had not been idle in watching over her own interests. She had named the Governor of St Christopher "Governor-General for the French West India Islands," and in 1641 he took possession of Tortuga for the Crown of France, expelled all English from the island, and attempted the same with less success in St Domingo. England had at home something vastly more important to attend to, and the Buccaneers had to maintain themselves as best they could,—now mainly on the sea.

In 1654 the Spaniards regained Tortuga from the French, into whose hands it again, however, fell after a period of six years. But this state of matters was, as may be readily conceived, too insecure even for these rovers, and they would speedily have succumbed to the perils of their mode of life, had not a refuge been found for them by the fortunate conquest of Jamaica in 1655 by the navy of Cromwell, on behalf of the English Commonwealth. These conquests were not made without the aid of the Buccaneers themselves. The taking and retaking of Tortuga by the French was always with the assistance of the roving community; and at the conquest of Jamaica the English navy had the same influence in its favour. The Buccaneers, in fact, by this time constituted a mercenary navy, ready for employment against the power of Spain by any other nation, on condition of sharing the plunder to be obtained; and they were noted for their daring, their cruelty, and their extraordinary skill in seamanship.

Their history now conveniently divides itself into three distinct epochs. The first of these extends from the period of their rise to the capture of Panama by Morgan in 1671, during which time their characteristic peculiarity as robbers was that they were hampered neither by Government aid nor, till near its close, by Government restriction. The second, from 1671 to the time of their greatest union and power, 1685, when the scene of their operations was no longer merely the Caribbean, but principally the whole range of the Pacific, from California to Chili. The third and last period extends from that year onwards; it was a time of disunion and disintegration, when the independence and rude honour of the previous periods had degenerated into unmitigated vice and brutality.

It is chiefly during the first period that those leaders flourished whose names and doings have been associated with all that was really influential in the exploits of the Buccaneers,—the most prominent being Mansvelt and Morgan. The commerce of Spain, which had been gradually dwindling since the wreck of the Invincible Armada and the death of Philip II., had by the middle of the 17th century become utterly insignificant. The Buccaneers were thus deprived of the plunder of the Spanish mercantile marine. But Spanish settlements remained; and in 1654 the first great expedition on land, attended by considerable difficulties, was completed by the capture and sack of New Segovia in Honduras, on the mainland of America. The Gulf of Venezuela, with its towns of Maracaibo and Gibraltar, were attacked and plundered under the command of a Frenchman named L'Ollenois, who performed, it is said, the office of executioner for the whole crew of a Spanish vessel manned with ninety seamen. Such successes removed the Buccaneers further and further from the pale of ordinary civilized society, fed their revenge, and inspired them with an avarice almost equal to that of the original settlers from Spain. Mansvelt, indeed, in 1664, popular among all the Buccaneers, conceived the idea of their permanently settling as a body of regular colonists upon a small island of the Bahamas, named Providence, and Henry Morgan, a Welshman, intrepid and unscrupulous, joined him in some preliminary cruises. But the untimely death of Mansvelt nipped in the bud the only rational scheme of permanent settlement which seems at any time to have animated the members of this wild community; and Morgan, now elected commander, swept the whole Caribbean, and from his headquarters in Jamaica led triumphant expeditions to Cuba and the mainland. He was leader of the expedition wherein Porto Bello, one of the chief and best fortified ports in the West Indies, was surprised, taken, and plundered.

But this was too much for even the adverse European powers; and in 1670 a treaty was concluded between England and Spain, proclaiming universal peace and friendship among the subjects of the two sovereigns in the New World, formally renouncing hostilities of every kind, withdrawing commissions granted to privateers, and agreeing to forget the past and for the future to punish all offenders. Great Britain was to hold all her possessions in the New World as her own property (a remarkable concession on the part of Spain), and consented, on behalf of her subjects, to forbear trading with any Spanish port without licence obtained. On the proclamation of the treaty in Jamaica, the Buccaneers rose to a man, ready for the most daring exploit which it had yet been in their power to achieve; they resolved to carry the terror of their name to the shores of the Pacific.

Accordingly, in 1671 Morgan embarked 2000 men on board a fleet of thirty-nine ships, sailed for a convenient port in the Caribbean, and crossed the Isthmus to lay siege to Panama. After a difficult journey, on foot and in canoes, they found themselves nearing the shores of the South Sea and in view of the turrets of the fated city. On the morning of the tenth day they commenced an engagement which, ere the close of the evening, ended in the rout of the defenders of the town. It was taken, and, accidentally or not, it was burnt. Neither sex nor condition was spared in the barbarities which ensued; and the conquerors returned laden with spoil. Morgan was not even true to his own men in the division of the booty; he returned to Jamaica, became respectable under Government, was after a little made deputy governor of the island, and took advantage of his position to punish his

former associates. He died, by the favour of Charles II, the "gallant" Sir Henry Morgan.

From 1671 to 1685 is the time of the greatest daring, prosperity, and maritime power of the Buccaneers. But the expedition against Panama had not been without its influence. Notwithstanding the vigour with which they executed their piratical projects in the Caribbean, and the many successes which they obtained on land, including a second plunder of the unfortunate city of Porto Bello, their thoughts ran frequently on the great expedition across the Isthmus, and they pictured to themselves the shores of the South Sea as a far wider and more lucrative field for the display of their united power.

In 1680 those longings took formidable shape. A body of marauders over 300 strong, well armed and provisioned, landed on the shore of Darien and struck across the country; and the cruelty and mismanagement displayed in the policy of the Spaniards towards the Indians were now in small part revenged by the assistance which the natives eagerly rendered to the adventurers. They acted as guides during a difficult journey of nine days, kept the invaders well supplied with food, provided them with skilfully constructed canoes, and only left them after the taking of the fort of Santa Maria, when the Buccaneers were fairly embarked on a broad and safe river which emptied itself into the South Sea. With John Coxon as commander they entered the Bay of Panama, where rumour had been before them, and where the Spaniards had hastily prepared a small fleet to quell this dangerous attempt to carry insecurity and terror into the Pacific. But the valour of the Buccaneers won for them another victory, and within a week they escaped from the confinement of canoes, and took possession of a small fleet of four Spanish ships; and now successes flowed upon them. The Pacific, formerly free from their intrusion, showed many sail of merchant vessels, while on land opposition south of the Bay of Panama was of little avail, since few were acquainted with the use of fire-arms, and defence as an art was utterly unknown Coxon and seventy of his men returned as they had gone, but the others under Sawkins, Sharp, and Watling, roamed north and south, on islands and mainland, and remained for long ravaging the coast of Peru. Never scant of silver and gold, but often in want of the necessaries of life, they continued their practices for a little longer; then, evading the risk of recrossing the Isthmus, they boldly cleared Cape Horn, and arrived in the Indies, in the not very tender hands of the representatives of the different Governments there. Again in 1683, however, numbers of them under John Cook departed for the South Sea by way of Cape Horn, near which they hailed a Thames built ship fitted out apparently as a trader, but in reality for the purposes of privateering. Thus straight from England the Buccaneers were now receiving a great accession to their numbers and their strength; and Eaton, the commander of the new vessel, told Cook of a certain Captain Swan who would probably be met with soon, prosecuting the same dangerous business. They sailed northward, and on the death of Cook, Edward Davis, undoubtedly the greatest and most prudent commander who ever led the forces of the Buccaneers at sea, took command of his ship. Davis parted with Eaton, who left for the East Indies, but Swan arrived, and the two captains began a cruise which was disastrous to the Spanish trade in the Pacific.

In 1685 they were joined in the Bay of Panama by large numbers of Buccaneers who had crossed the Isthmus under Townley and others. This increased body of men required an enlarged measure of adventure, and this in a few months was supplied by the Viceroy of Peru. That officer, sole representative of the Spanish sovereign in the vast kingdom, saw that the trade of the colony was cut off, that supplies were stopped, that towns were burned and cleared of the precious metals, and that settled life was broken in upon by the harassing and repeated attacks of the unsparing marauders, and he resolved by vigorous means to put an end to this state of matters. But this was not easily accomplished. In this same year, indeed, a fleet of fourteen sail hove in sight of the united forces of the Buccaneers in the Bay of Panama. The ten ships of the pirates were miserably deficient in cannon, and hung off. The Spaniards evidently were not aware of their advantage, and the two fleets, after remaining in proximity for three days, separated without testing their strength except in the way of a small and distant cannonade.

At this period the power of the Buccaneers was at its height. But the combination was now too extensive for its work, and the different nationality of those who composed it was a source of growing discord. Nor was the dream of equality ever realized for any length of time. The immense spoil obtained on the capture of wealthy cities was indeed divided equally among the crew of the attacking ships, the commander alone getting an extra share. But in the gambling and debauchery which followed, nothing was more common than that one-half of the conquerors should find themselves on the morrow in most pressing want; and while those who had prudently retained or fortunately increased their store of the precious metals would willingly have directed their course homewards, the others clamoured for renewed attacks upon the hated Spaniards. The separation of the English and French Buccaneers, who together presented a united front to the Spanish fleet in 1685, marks the beginning of the third and last epoch in their history—that of disunion, decay, and extinction as an unaided community.

The brilliant exploits begun in this third period by the sack of Leon and Realejo by the English under Davis have, even in their variety and daring, a sameness which deprives them of interest, and the wonderful confederacy is now seen to be falling gradually to pieces. The skill of Davis at sea was on one occasion displayed in a seven days' engagement with two large Spanish vessels, and the interest undoubtedly centres in him. Townley and Swan had, however, by this time left him, and after cruising together for some time, they, too, parted. In 1688 Davis cleared Cape Horn and arrived in the West Indies, while Swan's ship, the "Cygnet," was abandoned as unseaworthy, after sailing as far as Madagascar. Townley had hardly joined the French Buccaneers remaining in the South Sea ere he died, and the Frenchmen with their companions crossed New Spain to the West Indies. And thus the Pacific, ravaged so long by this powerful and mysterious band of corsairs, was at length at peace from California to Cape Horn.

The West Indies had by this time become hot enough even for the banded pirates. They hung doggedly along the coasts of Jamaica and St Domingo, but their day was nearly over. Only once again—at the siege of Carthagena—did they appear great; but even then the expedition was not of their making, and they formed an accession to regular forces organized in France. After the treachery of the French commander of this expedition a spirit of unity and despairing energy seemed reawakened in them; but this could not avert and scarcely delayed the rapidly approaching extinction of the community.

The proximate causes of the disappearance of this remarkable body of men are to be found in European policy. The accession of William of Orange to the English throne in 1689 had raised the jealousy of Louis XIV., and the war which ensued was protracted and severe. French and English rovers in the Caribbean could

not but take the part of their countrymen at home, and the continuance of hostilities effected the severance of the bond of unity which had for three-quarters of a century kept the subjects of the two nations together in schemes of aggression upon a common foe. The peace of Ryswick in 1697 only left England and France free to pay court to Spain, whose king, weak in body and mind, was evidently hastening to the grave. The succession to the crown was believed to depend upon his will, and the two nations used all their influence, both in the Old World and in the New, to ingratiate themselves into the favour of the Spanish monarch. But that which really stopped the career of the Buccaneers so effectually as to prevent its being resumed was the fact, of so vast importance in the history of Spain and of Europe, that in 1700 Philip V., first of the Bourbon dynasty, ascended the Spanish throne. Spain, so little in herself, yet always great under great kings, now degraded and fallen, almost immediately rose before the eyes of astonished Europe as a gigantic power in the Old World and in the New.

But the fall of the Buccaneers is no more accounted for fully by these circumstances than is their rise by the alienation and massacre of the islanders of St Domingo. There was that in the very nature of the community which, from its birth, marked it as liable to speedy decline.

The principles which bound the Buccaneers together were, first, the desire for adventure and gain, and, in the second place, hatred of the Spaniard. The first, as that which could produce union among men of different nationalities, hardly deserves to be called a principle. There was perhaps much to gain, but it could be had nearly always by private venture under the colours of the separate European powers. Only one thing prevented this, and it is connected with their second and great principle of union, namely, that they warred not with one another, nor with every one, but with a single and a common foe. For while the Buccaneer forces included English, French, and Dutch sailors, and were complemented occasionally by not inconsiderable bands of native Indians, the instances during the time of their prosperity and growth are few in which we find them turning upon one another, and treating their fellows with the savagery which they exulted in displaying against the subjects of Spain. The exigencies, moreover, of their perilous career readily wasted their suddenly acquired gains.

Settled labour, the warrant of real wealth, was beneath the dignity of those who lived by promoting its insecurity. Regular trade—though rendered attractive by smuggling—and pearl gathering and similar operations which were spiced with risk, were open in vain to them. For, as the licence of the debauchee was in almost every case substituted for the cares and pleasures of domestic life, so a hand-to-mouth system of supply and demand rooted out gradually the prudence which accompanies any mode of settled existence. In everything permanency was what was not aimed at, because the whole policy of the Buccaneers, from the beginning to the end of their career, was one of pure destruction, and was therefore ultimately suicidal.

It has already been seen how great was the influence of the Buccaneers upon the power and the colonial tactics of Spain. But it was more beneficial to the world and more ruinous to Spain, that they opened the eyes of the world, and specially of the nations from whom these Buccaneers had sprung, to the whole system of Spanish American government and commerce—the former in its rottenness, and the latter in its possibilities in other hands. That effected, all was effected, since the extent of Spanish power was known. From this, then, along with other causes, dating primarily from the helplessness and presumption of Spain, there arose the West Indian possessions of Holland, England, and France.

A work published at Amsterdam in 1678, entitled *Americaensche Zee Roovers*, from the pen of a Buccaneer named Exquemelin, was translated into several European languages, receiving additions at the hands of the different translators. The French translation by Oexmelin is named *Histoire des Avanturiers qui se sont signalez dans les Indes*; the English edition is entitled *The Bucaniers of America*. Other works are Raynal's *History of the Settlements and Trade of the Europeans in the East and West Indies*, book x., English translation 1782; Dampier's *Voyages*; Geo. W. Thornbury's *Monarchs of the Main, &c.*, 1855; Lionel Wafer's *Voyage and Description of the Isthmus of America*, 1699; and the *Histoire de l'isle Espagnole, etc.*, and *Histoire et description générale de la Nouvelle France* of Père Charlevoix. The statements in these works are to be received with caution. A really authentic narrative, however, is Captain James Burney's *History of the Buccaneers of America*, London, 1816. (T. S.)

BUCCARI, a royal free town of the Hungarian crown, situated in the comitat of Fiume, on a small bay of the Adriatic, in *45° 18′ 46″ N. lat.* and *14° 32′ 11″ E. long.* Its harbour is of rather limited dimensions, but the roadstead is excellent, though the approach is not unattended with danger. The staple industry is the weaving of linen; shipbuilding is also carried on, and there is an active coasting trade in fish, wine, wood, and coal. The tunny-fishery is of some importance. In the neighbourhood of the town is the old castle of Buccaricza, and further south the flourishing little port of Porto Rè or Kraljevicza. The population of Buccari in 1869 was 2116.

BUCCINO, a town of Italy in the province of Principato Citeriore, and district of Campagna, situated on the River Botta, which is here crossed by an ancient Roman bridge. Buccino is identified by means of inscriptions found on the spot, as the ancient *Volceium* or *Volcentium*, which was a considerable municipal town in Lucania. Population, 6049.

BUCER, MARTIN (1491–1551), originally MARTIN KUHORN, an eminent German reformer, born at Schelestadt, a town of Alsace, near Strasburg. At the age of fifteen he entered the order of St Dominic, and as he was a youth of great promise he was sent to prosecute his studies at Heidelberg. There he studied the works of Erasmus and Luther, and was present at a disputation of the latter with some of the Roman Catholic doctors. He became a convert to the Reformed Church, abandoned his order, and soon afterwards married a nun. He did not, however, remain strictly a Lutheran. On the great question of the sacrament of the Lord's Supper, his opinions were decidedly those of Zwingli rather than of Luther. Although differing from them in doctrine he was anxious to be in church unity with the Lutheran party, and constantly endeavoured to bring about a coalition. In 1548 he was sent for to Augsburg to sign the agreement, called the *Interim*, between the Papists and Protestants. His warm opposition to this project exposed him to many difficulties and hardships, which induced him to accept the invitation of Archbishop Cranmer to fix his residence in England. On his arrival, in 1549, he was appointed to teach theology in the university of Cambridge. King Edward VI. had the greatest regard for Bucer. Having heard that he had suffered much from the cold, from want of a German stove, he sent him a hundred crowns to purchase one. Bucer died of a complication of disorders in 1551, and was buried at Cambridge with great funeral pomp. Five years afterwards, in Mary's reign, his body was dug up and burnt, and his tomb demolished; but it was subsequently re-constructed by order of Queen Elizabeth. Bucer's name is familiar in English literature from the use made of the reformer's doctrines by Milton in his divorce treatises.

BUCH, LEOPOLD VON (1774–1853), an eminent German geologist and geographer, was born at Stolpe in Pomerania, April 25, 1774. In 1790 he studied at the mining school of Freiberg under the celebrated Werner, one of his

fellow-students there being the illustrious Alexander Von Humboldt. At the age of twenty-three he published his *Attempt at a Mineralogical Description of Landeck*, and also an *Attempt at a Geognostic Description of Silesia*. He was at this time a zealous upholder of the Neptunian theory of his illustrious master. In 1797 he met his old school-fellow Von Humboldt at Salzburg, and with him explored the geological formations of Styria and the adjoining Alps. In the spring of the following year, Von Buch extended his excursions into Italy, where his faith in the Neptunian theory was for the first time shaken. In his previous works he had advocated the aqueous origin of basaltic and other formations; he was now not less clearly convinced that these owed their existence to volcanic action. In 1799 he paid his first visit to Vesuvius, which he did not again see till 1805, when he was accompanied by Humboldt and Gay-Lussac. They had the good fortune to witness a remarkable eruption, which supplied Buch with data for refuting many erroneous ideas then entertained regarding the activity of volcanoes. Three years before he had explored the south of France, and directed special attention to the extinct volcanoes of Auvergne. The aspect of the Puy de Dome, with its cone of trachyte and its strata of basaltic lava, induced him to abandon as untenable the doctrines of Werner on the formation of these rocks. The scientific results of his investigations he embodied in his *Geognostical Observations during Travels through Germany and Italy*, Berlin, 1802–9, 2 vols. 8vo. From the south of Europe Von Buch repaired to the north, and spent two years among the Scandinavian islands, making many important observations on the geography of plants, on climatology, and on geology. He also established the fact that the whole of Sweden is slowly but continuously rising above the level of the sea from Frederickshall to Abo. The details of these discoveries are given in his *Travels through Norway and Lapland*, Berlin, 1810. In 1815 he visited the Canary Islands in company with Christian Smith, the Norwegian botanist. His observations here convinced him that these and other islands of the Atlantic owed their existence to volcanic action of the most intense kind, and that the groups of islands in the South Sea are the remains of a pre-existing continent. The physical description of the Canary Islands was published at Berlin in 1825. After leaving the Canaries Von Buch proceeded to the Hebrides and the coasts of Scotland and Ireland. His geological excursions even into countries already repeatedly visited were continued without interruption till his 78th year. Eight months before his death, he visited the mountains of Auvergne; and on returning home he read a paper on the Jurassic Formation before the Academy of Berlin. The circumstances of Von Buch's life were singularly favourable to scientific pursuits. He inherited from his father a fortune more than sufficient for all his wants. He was never married, and was completely unembarrassed by family ties. His excursions he always undertook on foot, with a staff in his hand, and the large pockets of his over-coat filled with papers and geological instruments. Under this guise, the passer-by would not easily have recognized the man whom Humboldt pronounced the greatest geologist of his time. He died at Berlin on the 4th of March 1853. In addition to the works already mentioned Von Buch published others, of which we may specify the magnificent *Geological Map of Germany*, in 42 sheets, Berlin, 1832.

BUCHANAN, George (1506–1582), a celebrated Scottish historian and scholar, was born in February 1506. His father, a younger son of an old family, was the possessor of the farm of Moss, in the parish of Killearn, Stirlingshire, but he died at an early age, leaving his widow and children in poverty. George, the third son, is said to have attended Killearn school, but not much is known of his early education. In 1520 he was sent by his uncle to the university of Paris, where he prosecuted his studies with great ardour, and especially trained himself in poetical composition. In 1522 his uncle died, and Buchanan being thus unable to continue longer in Paris, returned to Scotland. After recovering from a severe illness, he joined the French auxiliaries who had been brought over by the duke of Albany, and took part in an unsuccessful inroad into England. In the following year he entered the university of St Andrews, where he graduated as B.A. in 1525. He had gone there chiefly for the purpose of attending the celebrated John Major or Mair's lectures on logic; and when that teacher removed to Paris Buchanan accompanied him. In 1527 he became B.A., and in 1528 M.A. at Paris. Next year he seems to have been appointed regent or professor in the college of Ste Barbe, and taught there for upwards of three years. In 1532 he became the friend and tutor of Gilbert Kennedy, earl of Cassilis, with whom he returned to Scotland about the beginning of 1537.

While residing at Paris Buchanan had been converted to the Protestant faith, and his first production in Scotland was the poem *Somnium*, attacking with keen satire the Franciscan friars and monastic life generally. This assault on the monks was not displeasing to James V., who engaged Buchanan as tutor to one of his natural sons, and encouraged him to a still more daring attack. Under these circumstances the *Franciscanus* was written, and it is not surprising that the author became an object of bitterest hatred to all of the Roman Catholic faith. Nor was it yet a safe matter to assail the church. In 1539 there was a bitter persecution of the Lutherans, and Buchanan among others was arrested. He managed to effect his escape, and with considerable difficulty made his way to London and thence to Paris. At Paris, however, he found his resolute enemy, Cardinal Beaton, and on the invitation of Andrew Govea, proceeded to Bordeaux. Govea was then principal of the newly-founded college of Guienne at Bordeaux, and by his exertions Buchanan was appointed professor of Latin. During his residence there several of his best works, the translations of *Medea* and *Alcestis*, and his two great dramas *Jephthes* and *Baptistes*, were completed.

After three years he returned to Paris, and in 1544 was appointed regent in the college of Cardinal le Moine, a post he held till 1547. He then accepted Govea's invitation to a chair in the new Portuguese university of Coimbra, afterwards one of the most celebrated seats of learning in Europe. But he had not been long in Portugal when Govea's death exposed him to the unwearied persecution of the priests. Buchanan was several times examined by the officers of the Inquisition, and finally was confined to a monastery, where he was condemned to hear edifying lessons from the monks. During his imprisonment, which lasted several months, he began his famous version of the Psalms. On his release he sailed for England, but soon made his way to Paris, where, in 1553, he was appointed regent in the College of Boncourt. He remained in that post for two years, and then accepted the office of tutor to the son of the Marshal de Brissac.

In 1560 or 1561 he returned to Scotland, and in April 1562 we find him installed as tutor to the young queen Mary, who was accustomed to read Livy with him daily. Buchanan now openly joined the Protestant or Reformed Church, and in 1566 was appointed by the earl of Murray principal of St Leonard's College, St Andrews. Two years before he had received from the queen the valuable gift of the revenue resulting from Crossraguel Abbey. He was thus in good circumstances, and his fame was steadily increasing. So great, indeed, was his reputation

for learning and administrative capacity that, though a layman, he was made moderator of the General Assembly in 1567. He had sat in the Assemblies from 1563.

The part Buchanan took in the affairs of Queen Mary is well known. He accompanied the Regent Murray into England, and his *Detection* (published in 1572) was produced to the commissioners at Westminster. In 1570, after the assassination of Murray, he was appointed one of the preceptors of the young king, and it was through his tuition that James acquired his great scholarship. Buchanan was a strict and severe master, and kept his pupil in salutary awe and obedience. James long remembered the feelings of dread with which he was accustomed to regard his formidable pedagogue.

While discharging the functions of royal tutor he also held other important offices. He was for a short time director of chancery, and then became lord privy seal, a post which entitled him to a seat in the Parliament. He appears to have continued in this office for some years, at least till 1579. He died on the 28th September 1582.

His last years had been occupied with two of his most important works. The first was the treatise *De Jure Regni apud Scotos*, published in 1579. In this famous work, composed in the form of a dialogue, and evidently intended to instil sound political principles into the mind of his pupil, Buchanan lays down the doctrine that the source of all political power is the people, that the king is bound by those conditions under which the supreme power was first committed to his hands, and that it is lawful to resist, even to punish, tyrants. A theory such as this was not likely to be palatable to James. The book was condemned in 1584, and again in 1664; while in 1683 it was burned by the loyal scholars of Oxford.

The second of his large works was the history of Scotland, *Rerum Scoticarum Historia*, completed shortly before his death and published in 1582. It is of great value for the period personally known to the author, which occupies the greater portion of the book. The earlier part is to a considerable extent based on the work of Boece and repeats the legendary history which was for so long an article of faith to every Scotchman.

Buchanan is the greatest scholar that Scotland has produced. For mastery over the Latin language he has never been surpassed by any modern writer. His style is not rigidly modelled upon that of any classical author, but has a certain freshness and elasticity of its own. He wrote Latin as if it had been his mother tongue. But in addition to this perfect command over the instrument of expression, Buchanan had a rich vein of poetical feeling, and great powers of thought. His translations of the Psalms and of the Greek plays are more than mere versions; they have a peculiar grace and felicity. The smaller satirical poems are masterpieces of wit and expressive language, while the two tragedies, *Baptistes* and *Jephthes*, are works whose merits have not perhaps been generally recognized.

There are two complete editions of Buchanan's works, one by Ruddiman, 2 vols. fo., 1715; the other by Burman, 2 vols. 4to, 1725. His life has been written by Dr Irving, *Memoirs of the Life and Writings of George Buchanan*, 2d edition, 1817. The *Jephthah* and *Baptist* have been translated by A. Gibbs, 1870.

BUCHANAN, JAMES (1791–1868), fifteenth President of the United States, was born in Franklin County, Pennsylvania. His father, of the same name, was an Irishman who had eight years before emigrated from Donegal, and had become a well-to-do farmer. The son completed his education at Dickinson College, Carlisle, and took his degree in 1809. He then applied himself to the study of the law, was admitted to the bar in 1812, and settled at Lancaster in Pennsylvania. Notwithstanding his youth he soon gained considerable reputation, and with it a large and growing practice. In 1812 he joined a party of volunteers who, under the command of Judge Shippen, marched to the defence of Baltimore against the British; but their services were not wanted. He was at this time a zealous federalist. In 1814 he was elected member of the State Legislature, and constantly recommended the vigorous prosecution of the war. He was re-elected the following year; and in 1820 he became a member of Congress. Among his important early speeches were those on a deficiency in the military appropriation, in January 1822; on the bankrupt law, in March following, when he successfully opposed its extension to all citizens whether traders or not; and on the tariff question, on which he maintained that duties ought to be levied for revenue only. He uttered grave warnings against forming alliances with Mexico and the South American Republics, the condition of which was not calculated to inspire hopefulness, and insisted on the immense importance of Cuba, both commercially and strategically, to the United States. In 1828 he supported General Jackson at the Presidential election, and was at the same time re-elected to Congress. In the following year he succeeded Daniel Webster as head of the judiciary committee, and in this capacity conducted the trial on impeachment of Judge Peck,—one of the *causes célèbres* of American jurisprudence. On completing his fifth term, Buchanan retired from Congress (1831), and the next year was appointed envoy extraordinary and minister plenipotentiary to St Petersburg. His mission is marked by the negotiation of the first treaty of commerce between the United States and Russia,—a treaty by which important privileges in the Baltic and the Black Sea were secured to the former. On his return from Russia he was elected United States senator; and he retained his seat till 1845. In the great struggle between President Jackson and the party headed by Mr Calhoun, Buchanan warmly defended the president and his claims. In the first years of the movement against slavery, he saw the large results which were likely to follow, and desired to suppress the agitation in its infancy, and this by suppressing the discussion of the subject in Congress. He advocated the recognition by Congress of the independence of Texas, and at a later time its annexation. During the presidency of Van Buren, Buchanan greatly distinguished himself in support of the principal measure of the Government—the establishment of an independent treasury. In 1845 he was appointed Secretary of State under President Polk; and at the close of his term of office in 1849 he retired into private life. But four years later he accepted from President Pierce the post of United States Minister to Great Britain. In 1854 he was the originator and one of the three members of the Ostend Conference on the subject of the acquisition of Cuba by the United States, and with his colleagues maintained that, on the principle of self-preservation from dangers of the gravest kind, an armed intervention of the United States and the capture of the island from the Spaniards would be justifiable. He returned from England in 1856, and the same year was elected, as Democratic candidate, to the Presidential chair. For a short time there seemed to be ground for hope that political passions and excitement would subside. But this hope was soon found to be fallacious. The troubles in Kansas and the large questions involved in them gave rise to new discussions and division. The president gave his support to the pro-slavery party, and dissensions grew during his administration to such an extent that disruption and war between North and South followed the election of his successor, President Lincoln. From the close of his administration in 1860 till his death, Buchanan led a retired life. He died at Wheatland in Pennsylvania, June 1, 1868. Two years before his death he published an account of his administration.

fellow-students there being the illustrious Alexander Von Humboldt. At the age of twenty-three he published his *Attempt at a Mineralogical Description of Landeck*, and also an *Attempt at a Geognostic Description of Silesia*. He was at this time a zealous upholder of the Neptunian theory of his illustrious master. In 1797 he met his old school-fellow Von Humboldt at Salzburg, and with him explored the geological formations of Styria and the adjoining Alps. Two years before he had received from the queen the valuable gift of the revenue resulting from Crossraguel Abbey. He was thus in good circumstances, and his fame was steadily increasing. So great, indeed, was his reputation

BUCHAREST, Bukhorest, Bukorest, or, as it is called by the inhabitants, Bucuresci (that is, according to their own etymology, City of Joy), is the capital of Roumania, the residence of the prince and the seat of a bishop. It is situated in a hollow on the River Dimbovitza, a tributary of the Danube, in 44° 25′ 30″ N. lat. and 26° 5′ 24″ E. long., and occupies an area of more than 20 English square miles. The number of its cupolas and minarets, and the profusion of acacia, poplar, and other trees that fill the numerous spaces of unoccupied ground, give it a picturesque appearance from a distance. The arrangement of its streets is very irregular, and in many districts it cannot be said that there are streets at all. In general the roadways are either unpaved or only laid with rough blocks of different sizes. A few streets, indeed (and notably the Podo Mogochoi, which is the most important), have been paved with Aberdeen granite. The city is lighted with gas produced from English coal; and a considerable but far from satisfactory supply of water is obtained from the river and distributed partly by water-carts and partly by iron pipes. Of the public buildings few are of much architectural importance; the national theatre is one of the largest, and the "academy" one of the finest. The latter is occupied by the university, a library of 26,000 volumes, a public museum of antiquities and natural history, and a large theatre, which is used by the senate during the parliamentary session. The palace, an insignificant building, was founded by the Golesco family in the 18th century. There are 116 Greek churches in the city, of which the most remarkable are the Metropolitan, St George, St Spiridion, and Sarindar. The Roman Catholics have a parish-church in the centre of the town and several chapels; there are Lutheran and Calvinistic churches, with schools attached for both boys and girls; and the Jews, who number about 15,000, have ten synagogues. There are about a score of conventual establishments, the majority belonging to the Greek Church. The Brancovano hospital, founded by the family of that name, has accommodation for between 200 and 300 patients, the military hospital for 300, the Culza for 200, the Philanthropic for 100, and the Pantelemonu for 120. The Marcutza insane asylum can receive 220; and the Helena asylum, founded by the Princess Helena in 1862, has room for 220 orphan girls. There is also a children's hospital for 100 patients, and a lying-in hospital for 40. In Bucharest there is always a numerous garrison, and the arsenal and barracks on the plateau of Dealu and the cavalry and infantry barracks at St George are both extensive establishments. Cafés and coffee-gardens abound, and are allowed to remain open all night. There are two public gardens, the Cismegiu in the centre of the town, about a mile in circumference, and the Kisilev on the outskirts, which is traversed by the fashionable promenade known as the Chaussée. Public locomotion is facilitated by about 500 droshkas in summer and as many sledges in winter; and a tramway has recently been laid down by an English company. The monetary business of the city is extensive,—its principal establishments being the Bank of po- Roumania, founded in 1865, with a capital of one million instr-sterling, and the *Société Financière de Roumanie*, with a easily -pital of six million francs. drivers are mainly Russians of the Lipovani sect; and Bulgarians, Armenians, gypsies, and many others swell the motley multitude. In spite of the fact that the number of deaths is frequently in excess of the number of births, the increase of the population is rapid, and house-rents have become very high; and that it is more the habits of the people than the unhealthiness of the city that is to blame for the death-rate is shown by the steady internal increase of the Jewish community. About eighteen newspapers are published in the city—three daily and the others twice or thrice a week. The railway system, begun by the opening of the line to Giurgevo on the Danube in 1869, is rapidly extending, and there is direct communication with Western Europe by the line to Lemberg. The population, which was 121,754 in 1859, had increased by 1870 to 200,000, and is now stated at 251,000.

Bucharest owes its foundation in the 13th century to Radel the Black of Wallachia. Burnt in 1595 by Sinan Pasha it was soon afterwards restored, but it was not till the 18th century that it appeared much in European history. It was frequently of importance in the contests for the neighbouring provinces, which so often broke out between the Turks and their northern rivals Austria and Russia; and in 1812 it gave its name to the treaty by which Bessarabia and a third of Moldavia were ceded to the latter power. In the war of 1828 it was occupied by the Russians, who made it over to the prince of Wallachia in the following year. A rebellion against Prince Bibesko in 1848 brought both Turkish and Russian interference, and the city was again held by Russian troops from 1853 to 1854. On their departure an Austrian garrison took possession and remained till March 1857. In 1858 the international congress for the organization of the Danubian principalities was held in the city; and in 1861 the union of Wallachia and Moldavia was proclaimed. Prince Couza, the first ruler of the united provinces, was driven from his throne by an insurrection in Bucharest in 1866.

BUCHEZ, Philippe Joseph Benjamin (1796–1865), French author and politician, was born at Matagne-la-Petite, in the department of the Ardennes. He finished his general education in Paris, and afterwards applied himself to the study of natural science and medicine. Hatred of the Government of the Restoration, and enthusiasm for democratic ideas, were at that time widely diffused among the young men of the schools of Paris, and these passions gained full possession of the mind of Buchez. With his friends Bazard and Flotard he founded, in 1821, a secret association—a system of French carbonarism—which spread rapidly and widely, and displayed itself in repeated attempts at revolution. In one of these attempts—the affair at Belfort—which cost General Berton, Colonel Caron, and four soldiers of Rochelle their lives, he was gravely compromised, although the jury which tried him did not find the evidence sufficient to warrant his condemnation. In 1825 he graduated in medicine, and soon after he published, along with M. Trelat, a *Précis élémentaire d'Hygiène*. About the same time he became a member of the Saint-Simonian Society, presided over by Bazard, Enfantin, and Rodriguez, and contributed to its organ, the *Producteur*. He left it in consequence of aversion to the strange theological dogmas of its spiritual chief, M. Enfantin, and began to elaborate what he regarded as a Christian socialism. For the exposition and advocacy of his principles he founded a periodical called *L'Européen*. In 1833 he published an *Introduction à la Science de l'Histoire*, which was received with considerable favour, and of which a second edition, improved and enlarged, in two volumes, appeared in 1842. Notwithstanding its prolixity and discursiveness, this is both an interesting and a meritorious work. The part of it which treats of the aim ... methods of the science

of history is truly valuable. On the other hand, what is most distinctive in M. Buchez's theory—the division of historical development into four great epochs originated by four universal revelations, of each epoch into three periods corresponding to desire, reasoning, and performance, and of each of these periods into a theoretical and practical age—seems entitled to no higher commendation than that of being ingenious. (See Flint's *Philosophy of History in Europe*, i., 242–252). M. Buchez next edited, along with M. Roux Laverne, the *Histoire parlementaire de la Révolution Française* (1833–38, 40 vols). This vast, laborious, conscientious publication is one of the chief sources of information regarding the early periods of the first French Revolution. There is a review of it by Mr Carlyle (*Miscellanies*), the first two parts of whose own history of the French Revolution are mainly drawn from it. The editors worked under the inspiration of a strong admiration of the principles of Robespierre and the Jacobins, and in the belief that the French Revolution was an attempt to realize Christianity.

M. Buchez gave a general exposition of his views in his *Essai d'un Traité complet de Philosophie au point de vue du Catholicisme et du progrès* (3 vols. 1839–40). Perhaps the fundamental doctrine of this treatise is that the primitive, intellectual, moral, and religious ideas of men cannot be adequately explained as innate, or as derived from sensation, sentiment, or reasoning, but must have been imparted by divine revelation. It is substantially identical with the fundamental doctrine of De Bonald, although Buchez infers from it democratic instead of theocratic consequences. Great prominence is given to the conception of progress which is attained by generalization from a comprehensive survey of geology, physiology, and history. The author sets very distinctly before himself also the aim of organizing the sciences into a single comprehensive system. This he thought could only be accomplished through an *a priori* synthetic method, and not, as had previously been attempted, by the analytical and experimental method. It was partly owing to the reputation which he had acquired by these publications, but still more owing to his connection with the *National* newspaper, and with the secret societies hostile to the Government of Louis Philippe, that he was raised, by the Revolution of 1848, to the presidency of the Constituent Assembly. He speedily showed that he was not possessed of the firmness, decision, and political capacity needed in a situation so difficult and in days so tempestuous. He retained the position only for a very short time. After the dissolution of the Assembly he was not re-elected. Thrown back into private life, he resumed his studies, and added several works to those which have been already mentioned. A *Traité de Politique*, which may be considered as the completion of his *Traité de Philosophie*, is the most important of the productions of the last period of his life. His brochures are very numerous and on a great variety of subjects, medical, historical, political, philosophical, &c. He died in 1865. He found a disciple of considerable ability in M. Ott, who has advocated and applied his principles in various writings, the most recent of which, perhaps, places the metaphysical theory of Buchez in as favourable a light as it can be seen under. (R. F.)

BUCHU or BUKA LEAVES are the produce of several shrubby plants belonging to the genus *Barosma* (Nat. Order, *Rutaceæ*), natives of the Cape of Good Hope. The principal species, *B. crenulata*, has leaves of a smooth leathery texture, oblongo-ovate in shape, from an inch to an inch and a half in length, with serrulate or crenulate margins, on which as well as on the under side are conspicuous oil cells. The other species which yield buchu are *B. serratifolia*, having linear-lanceolate sharply serrulate leaves, and *B. betulina*, the leaves of which are cuneate obovate, with denticulate margins. They are all, as found in commerce, of a pale yellow-green colour; they emit a peculiar aromatic odour, and have a slightly astringent bitter taste. Buchu leaves contain a volatile oil, to which evidently their therapeutic influence is due, and are said to yield a bitter extractive principle, which has received the name of diosmin. The leaves of a closely allied plant, *Empleurum serratulum*, are employed as a substitute or adulterant for buchu. Buchu leaves are chiefly used in European pharmacy in inflammatory disorders of the bladder and urinary organs; in the United States they are much employed by vendors of secret medicines. An infusion of the leaves is tonic, sudorific, and diuretic. At the Cape buchu has great reputation in gout and rheumatism, and as a stomachic stimulant; and in the form of buchu brandy and buchu vinegar it is applied as an embrocation in sprains, contusions, and rheumatic pains.

BÜCKEBURG, the capital of the principality of Schaumburg-Lippe, is situated at the foot of the Harrlberg on the River Aue, about 6 miles from Minden, on the Minden and Hanover Railway. It has a castle surrounded by a park, a gymnasium, a normal seminary, a library, an orphanage, a synagogue, and three churches, one of which has the appropriate inscription, *Religionis non structuræ exemplum*. The first houses of Bückeburg began to gather round the castle about 1365; and it was not till the 17th century that the town was surrounded with walls. Population in 1871, 4686.

BUCKINGHAM, COUNTY OF, BUCKINGHAMSHIRE, or BUCKS, an inland county of England, between 51° 25′ and 52° 10′ N. lat., and 0° 28′ and 1° 12′ W. long., is bounded N. by Northamptonshire W. by Oxfordshire, S. by Berkshire, and E. by Bedfordshire, Hertfordshire, and Middlesex. It is the thirty-third in size of the English counties, measuring 53 miles at its greatest length and 27 at its greatest breadth, and containing, according to the last ordnance survey, 467,009 acres, or nearly 730 square miles. The aspect of the country is agreeably diversified by the distribution of forests, rivers, hills, pasture, and arable land. In the southern portion of the county the forests, consisting chiefly of beeches (from the Saxon name of which tree, *boc*, the county is said to derive its name), were at one time very extensive, but have of late years been greatly thinned; woods of considerable extent are still to be found in the northern parts. The principal rivers of Buckinghamshire are the Thames, which separates

For map see OXFORD.

site of the old castle, has a handsome spire, 150 feet high, and has been restored and extended under the direction of Sir G. G. Scott, who was born in the neighbourhood. There are also a jail, a union workhouse, and several dissenting churches. An endowed free school for boys, who were clad in green coats by the will of the founder, Gabriel Newton, is now incorporated with the national school, which is intended to accommodate 300 pupils. The grammar-school of the town was founded by Edward VI., and occupies the chapel of the guild of the Holy Trinity, founded by Archdeacon Stratton in 1268. The manufactures, which include bone-grinding, malt-making, and tanning, are of comparatively small importance. Lace-making with bobbins still occupies a small part of the female population. There are also some corn-mills in the neighbourhood, and a few lime quarries. The borough of Buckingham formerly returned two members to Parliament, but since 1868 it has only returned one. It is governed by a mayor, four aldermen, and twelve councillors. Population of parliamentary borough in 1871, 7545; of municipal borough, 3703. Buckingham is a town of great antiquity. It was fortified with earthen ramparts by Edward the Elder in 918, and in 1010 it was captured by the Danes. It is mentioned as an ancient borough in *Domesday Book*, but does not seem to have returned members to Parliament till the reign of Henry VIII. In the reign of Edward III it was a wool-staple, but not long after its prosperity began to decline. From Queen Mary it received a charter in 1554. It was the headquarters of Charles I. for a few days during his war with the Parliament. In 1725 a third part of the town was burnt to the ground.

BUCKINGHAM, GEORGE VILLIERS, DUKE OF (1592–1628), born August 20, 1592, was a younger son of Sir George Villiers of Brooksby. His mother, who was left a widow early, educated him for a courtier's life, and the lad, being by nature little studious and contemplative, took kindly to the training. He could dance well, fence well, and talk a little French, when in August 1614 he was brought before the king's notice, in the hope that he would take a fancy to him.

The moment was favourable Since Salisbury's death James had taken the business of government upon himself. But he wanted some one who would chat with him, and amuse him, and would also fill the office of private secretary, and save him from the trouble of saying No to importunate suitors. It would be an additional satisfaction if he could train the youth whom he might select in those arts of statesmanship of which he believed himself to be a perfect master. His first choice had not proved a happy one. Robert Carr, who had lately become earl of Somerset, had had his head turned by his elevation. He had grown peevish toward his master, and had placed himself at the head of the party which was working for a close alliance with Spain.

The appearance of Villiers, beaming with animal spirits and good humour, was therefore welcomed by all who had an interest in opposing the designs of Spain. With such powerful backing Villiers prospered at court, became a gentleman of the bed-chamber, was knighted, and received a pension of £1000 a year. For some little time, however, Somerset's pre-eminence was maintained. But the charge of murder brought against him completed his ruin, and Villiers at once stepped into the place which he had vacated. In August 1616 he was raised to the peerage as Viscount Villiers. In January 1617 he became earl of Buckingham. In January 1618 he was a marquis by the same title. Estates to the value of some £15,000 a year were settled on him. With the exception of the earl of Pembroke he was the richest nobleman in England.

Those who expected him to give his support to the anti-Spanish party were at first doomed to disappointment. As yet he was no politician, and he contented himself with carrying out his master's orders, whatever they were. In his personal relations he was kindly and jovial towards all who did not thwart his wishes. But James had taught him to consider that the patronage of England was in his hands, and he took good care that no man should receive promotion of any kind who did not in one way or another pay court to him. As far as can be ascertained, he cared less for money than for the gratification of his vanity. But he had not merely himself to consider. His numerous kinsfolk were to be enriched by marriage, if in no other way, and Bacon, the great philosopher and statesman, was all but thrust from office, because he had opposed a marriage suggested for one of Buckingham's brothers, whilst Cranfield, the first financier of the day, was kept from the Treasury till he would forsake the woman whom he loved, to marry a penniless cousin of the favourite.

In the meanwhile Buckingham had found an appropriate position in the mastership of the horse, which gave him control over the royal stables. In January 1619 James made him lord high admiral of England, hoping that the ardent, energetic youth would impart something of his own fire to those who were intrusted with the oversight of that fleet which had been almost ruined by the peculation and carelessness of the officials. Something of this, no doubt, was realized under Buckingham's eye. But he himself never pretended to the virtues of an administrator, and he was too ready to fill up appointments with men who flattered him, and too reluctant to dismiss them, if they served their country ill, to effect any permanent change for the better.

It was about this time that he first took an independent part in politics. All England was talking of the revolution in Bohemia in the year before, and men's sympathy with the Continental Protestants was increased when it was known that James's son-in-law had accepted the crown of Bohemia, and that in the summer of 1620 a Spanish force was preparing to invade the Palatinate. Buckingham at first had thrown himself into the popular movement. Before the summer of 1620 was at end he had swung round, and was in close agreement with Gondomar, the Spanish ambassador. He had now married Lady Catherine Manners, the daughter of the earl of Rutland, who was at heart a Roman Catholic, though she outwardly conformed to the English Church, and this alliance may have had something to do with the change.

Buckingham's mistakes were owing mainly to his levity. If he passed briskly from one camp to the other, an impartial observer might usually detect some personal motive at the bottom. But it is hardly probable that he was himself conscious of anything of the sort. When he was in reality acting under the influence of vanity or passion it was easy for him to persuade himself that he was doing his duty to his country.

The Parliament which met in 1621 broke out into a loud outcry against the system of monopolies, from which Buckingham's brothers and dependants had drawn a profit, which was believed to be greater than it really was. At first he pleaded for a dissolution. But he was persuaded that it would be a wiser course to offer to put himself at the head of the movement, and when he came forward to say that he would rather sacrifice his brother than countenance wrong doing, he only gave utterance to those sentiments of patriotism which he really felt, when patriotism did not call upon him to sacrifice his own wishes. When, at a later period of the session, Bacon's case was brought forward, he made no attempt to meet the attack directly, but he did his best to shield the falling chancellor from the extreme penalties demanded by his adversaries. It was not long before he showed on how shallow a basis impulsive generosity rests. Bacon clung, after his fall, to the [illegible] of

provisions, and without money to buy them, the wretched troops sickened and died in the winter frosts. Buckingham's first military enterprise ended in disastrous failure.

Buckingham had many other schemes in his teeming brain. He had offered to send aid to Christian IV., king of Denmark, who was proposing to make war in Germany, and had also a plan for sending an English fleet to attack Genoa the ally of Spain, and a plan for sending an English fleet to attack Spain itself.

Before these schemes could be carried into operation James died on March 27, 1625. The new king and Buckingham were at one in their aims and objects. Both were anxious to distinguish themselves by the chastisement of Spain, and the recovery of the Palatinate. Both were young and inexperienced. But Charles, obstinate when his mind was made up, was sluggish in action and without fertility in ideas, and he had long submitted his mind to the versatile and brilliant favourite, who was never at a loss what to do next, and who unrolled before his eyes visions of endless possibilities in the future. Buckingham was sent over to Paris to urge upon the French Court the importance of converting its alliance into active co-operation.

There was a difficulty in the way. The Huguenots of Rochelle were in rebellion, and James had promised the aid of English ships to suppress that rebellion. Buckingham, who seems at first to have consented to the scheme, was anxious to mediate peace between the king of France and his subjects, which would set him free from foreign enterprises, and save Charles from compromising himself with his Parliament by the appearance of English ships in an attack upon Protestants. When he returned his main demands were refused, but hopes were given him that peace would be made with the Huguenots. On his way through France he had the insolence to make love to the Queen of France. Unless the testimony of his warmest admirers is false, he had convinced himself by a sad experience that women found it difficult to resist his seductive tongue and his handsome face.

Soon after his return Parliament was opened. It would have been hard for Charles to pass through the session with credit. Under Buckingham's guidance he had entered into engagements involving an enormous expenditure, and these engagements involved a war on the Continent, which had never been popular in the House of Commons. The Commons, too, suspected the marriage treaty contained engagements of which they disapproved. They asked for the full execution of the laws against the Catholics, and voted but little money in return. Charles adjourned then to Oxford, that he might plead with them more persuasively. Before they met there, the English ships had found their way into the hands of the French, to be used against Rochelle. The Commons met in an ill-humour. They had no confidence in Buckingham, and they asked that persons whom they could trust should be admitted to the king's council before they would vote a penny. Charles stood by his minister, and on August 12 he dissolved his first Parliament.

Buckingham and his master set themselves to work to conquer public opinion. On the one hand, they threw over their engagements to France on behalf of the English Catholics. On the other hand they sent out a large fleet to attack Cadiz, and to seize the Spanish treasure-ships. Buckingham went to the Hague to raise an immediate supply by pawning the crown jewels, to place England at the head of a great Protestant alliance, and to enter into fresh obligations to furnish money to the king of Denmark. It all ended in failure. The fleet returned from Cadiz having effected nothing. The crown jewels produced but a small sum, and the money for the king of Denmark could only be raised by an appeal to Parliament. In the meanwhile the king of France was deeply offended by the treat-

ment of the Catholics, and by the seizure of French vessels on the ground that they were engaged in carrying goods for Spain.

When Charles's second Parliament met on February 6, 1626, it was not long before, under Eliot's guidance, it asked for Buckingham's punishment. He was impeached before the House of Lords on a long string of charges. Many of these charges were exaggerated, and some were untrue. But as long as Charles refused to listen to the complaints of his minister's incompetency, the only way in which the Commons could reach him was by bringing criminal charges against him. Charles dissolved his second Parliament as he had dissolved his first.

To find money was the great difficulty. Recourse was had to a forced loan, and men were thrown into prison for refusing to pay it. There had been disasters to Charles's allies in Germany, and a French war was impending in addition to the Spanish one. The French were roused to reprisals by Charles's persistence in seizing French vessels. Unwilling to leave Rochelle open to the entrance of an English fleet, Richelieu laid siege to that stronghold of the French Huguenots. On June 27, 1627, Buckingham sailed from Portsmouth at the head of a numerous fleet, and a considerable land force, to relieve the besieged city.

His first enterprise was the siege of the fort of St Martin's, on the Isle of Rhé. The ground was hard, and the siege operations were converted into a blockade. On September 27, the defenders of the fort announced their readiness to surrender the next morning. In the night a fresh gale brought over a flotilla of French provision boats, which dashed through the English blockading squadron. The fort was provisioned for two months more. Buckingham resolved to struggle on, and sent for reinforcements from England. Charles would gladly have answered to his call. But England had long since ceased to care for the war. There was no money in the exchequer, no enthusiasm in the nation to supply the want. Before the reinforcements could arrive the French had thrown a superior force upon the island, and Buckingham was driven to retreat with heavy loss.

His spirits were as buoyant as ever. Ill luck, or the misconduct of others, was the cause of his failure. He had new plans for carrying on the war. But the Parliament which met on March 17, 1628, was resolved to exact from the king an obligation to refrain from encroaching for the future on the liberties of his subjects.

In the parliamentary battle, which ended in the concession of the Petition of Right, Buckingham took an active share as a member of the House of Lords. He resisted as long as it was possible to resist the demand of the Commons, that the king should abandon his claim to imprison without showing cause. When the first unsatisfactory answer to the petition was made by the king on June 2, the Commons suspected, probably with truth, that it had been dictated by Buckingham. They prepared a remonstrance on the state of the nation, and Coke at last named the duke as the cause of all the misfortunes that had occurred. Though on June 7 the king granted a satisfactory answer to the petition, the Commons proceeded with their remonstrance, and on June 11 they informed the king that Buckingham had "so abused his powers," that it was no longer safe to continue him in office.

Once more Charles refused to surrender Buckingham, and a few days later he prorogued Parliament in anger. The popular feeling was greatly excited. Lampoons circulated freely from hand to hand, and Dr Lambe, a quack doctor, who dabbled in astrology, and was believed to exercise influence over Buckingham, was murdered in the streets of London. Rude doggerel lines announced that the duke should share the doctor's fate.

With the clouds gathering round him, Buckingham went down to Portsmouth to take the command of one final expedition for the relief of Rochelle. For the first time even he was beginning to acknowledge that he had undertaken a task beyond his powers. There was a force of inertia in the officials which resisted his efforts to spur them on to an enterprise which they believed to be doomed to failure. He entered gladly into a scheme of pacification proposed by the Venetian ambassador. But before he could know whether there was to be peace or war, the knife of an assassin put an end to his career. John Felton, who had served at Rhé, had been disappointed of promotion, and had not been paid that which was due to him for his services, read the declaration of the Commons that Buckingham was a public enemy, and eagerly caught at the excuse for revenging his private wrongs under cover of those of his country. Waiting, on the morning of August 23, beside the door of the room in which Buckingham was breakfasting, he stabbed him to the heart as he came out. The man who for four years had been practically the ruler of England fell dead upon the ground. He had only completed his thirty-sixth year three days before. (S. R. G.)

BUCKINGHAM, GEORGE VILLIERS, SECOND DUKE OF (1627–1688), was born at London January 30, 1627, about a year and a half before the murder of his father. He was educated at Cambridge, returned from a Continental tour on the outbreak of the civil war, and at once threw in his lot with the king. The detachment in which he held a command was defeated at Nonsuch, and he with difficulty effected an escape from England. His estates were confiscated by Parliament, and part of them were bestowed upon Fairfax. He returned with Charles II. and took part in the battle of Worcester, after which he again fled. About 1657 he returned secretly to England and married one of Fairfax's daughters. Arrested by order of Cromwell, he was thrown into the Tower and kept in confinement for some time. After the Restoration he recovered his estates, and rose to high favour with Charles II. He was a man of great talent, but utterly without principle, versatile and whimsical to the last degree.

> "A man so various that he seemed to be
> Not one, but all mankind's epitome."

He was a profligate and a statesman, a musician, an alchemist, a writer of farces, and a courtier,—"everything by starts, and nothing long." He was radically fickle, and could not be faithful to any party. In 1671 his power was at its height. He had done much to bring about the dismissal of Clarendon, had formed the famous council called the Cabal, and was in fact prime minister of England. But the measures he and his associates passed were little calculated to allay the strong popular feeling against the Government. The Cabal was quickly dissolved, and Buckingham, with his usual versatility, at once became an ardent friend of the democratic leaders. Soon afterwards he seems to have been disgusted with politics, and gradually withdrew from court. After the death of Charles he retired to his seat at Helmsley in Yorkshire, and devoted himself to hunting and other country amusements. He died on the 17th April 1688, in the house of one of his tenants, having been seized with a fever produced by sitting on the damp ground after being heated with riding. He was buried in Westminster Abbey. Buckingham was the author of some farces, comedies, and miscellaneous poems, but he is chiefly remembered in English literature by the *Rehearsal*, a clever parody upon Dryden and other stilted tragedians. His works were collected in 1704.

BUCKINGHAMSHIRE, JOHN SHEFFIELD, DUKE OF (1649–1721), was the son of Edmund, second earl of Mulgrave, and succeeded to that title on his father's death in 1658. At the age of seventeen he joined the fleet in

the external world are sublime and terrible, the understanding being emboldened and the imagination curbed when they are small and feeble; 4. That the great division between European and non-European civilization turns on the fact that in Europe man is stronger than nature, and that elsewhere nature is stronger than man, the consequence of which is that in Europe alone has man subdued nature to his service; 5. That the advance of European civilization is characterized by a continually diminishing influence of physical laws, and a continually increasing influence of mental laws; 6. That the mental laws which regulate the progress of society cannot be discovered by the metaphysical method, that is, by the introspective study of the individual mind, but only by such a comprehensive survey of facts as will enable us to eliminate disturbances, that is, by the method of averages; 7. That human progress has been due, not to moral agencies, which are stationary, and which balance one another in such a manner that their influence is unfelt over any long period, but to intellectual activity, which has been constantly varying and advancing:—"The actions of individuals are greatly affected by their moral feelings and passions; but these being antagonistic, to the passions and feelings of other individuals, are balanced by them, so that their effect is, in the great average of human affairs, nowhere to be seen, and the total actions of mankind, considered as a whole, are left to be regulated by the total knowledge of which mankind is possessed;" 8. That individual efforts are insignificant in the great mass of human affairs, and that great men, although they *exist*, and must "at present" be looked upon as disturbing forces, are merely the creatures of the age to which they belong; 9. That religion, literature, and government are, at the best, the products and not the causes of civilization; 10. That the progress of civilization varies directly as "scepticism," the disposition to doubt and to investigate, and inversely "as credulity" or "the protective spirit," a disposition to maintain, without examination, established beliefs and practices.

These are all the general truths which are contained in Buckle's theory of history. And obviously, however ably advocated, however solidly established they might be, they must fall short of constituting a science of history, unless that science be one of unparalleled simplicity and vagueness. But probably none of them are completely made out; probably none of them are quite true; while several of them seem to be nearly altogether false. Buckle either could not define, or cared not to define, the general conceptions with which he worked, such as those denoted by the terms "civilization," "history," "science," "law," "scepticism," and "protective spirit;" the consequence is that his arguments are often fallacies. Whenever he treats of matters metaphysical, psychological, or theological, he shows plainly that his mind had been little exercised on such subjects. He assumes, without the slightest evidence, that law and free will, orderly historical development and providential government, the metaphysical method and the method of averages, obeying nature and ruling nature, are so many alternatives of which the terms contradict and exclude each other; it does not seem to have occurred to him that freedom and law, historical order and providential government, internal and external observation, might co-exist, or that Bacon might have had reason in writing—"*natura non nisi parendo vincitur*." The looseness of his statements and the rashness of his inferences regarding statistical averages make him, as a great authority has remarked, the *enfant terrible* of moral statisticians. He denies the influence of race without adequate consideration, and so exaggerates the power of climate, soil, food, and the aspects of nature, as at times to be fairly chargeable with physical fatalism. He neglects to raise the essential question, Must not certain moral conditions be realized before the accumulation and distribution of wealth are possible? In attempting to prove the unprogressiveness of moral knowledge he gives us such assertions as these:—"That the system of morals propounded in the New Testament contained no maxim which had not been previously enunciated, and that some of the most beautiful passages in the Apostolic writings are quotations from Pagan authors is well known to every scholar." "Systematic writers on morals reached their zenith in the 13th century, fell off rapidly after that period, were, as Coleridge well says, opposed by the 'genius of Protestantism,' and by the end of the 17th century became extinct in the most civilized countries,"—although the facts are, that the passages in the Apostolic writings known to be quotations from Pagan authors are just three in number, two of which have no claims to beauty, and that there have been more systematic writers on morals in the 19th century than there were writers of all kinds during the 13th. The reasoning employed to show that intellectual forces have been far more potent than moral forces in producing progress has many flaws, which have been often pointed out. What Buckle himself says of the achievements of Richelieu, Adam Smith, Voltaire, and others, and of the effects of the protective spirit in France and England, and of religious intolerance in Spain and Scotland, is irreconcilable with his doctrines that great men, government, and religion have had almost no influence on civilization. His paradox about scepticism and credulity is partly a truism inaccurately expressed and partly its exaggeration.

The larger part of Buckle's first volume, and the whole of the second, are composed of surveys of positive history, undertaken to prove the last of the general theses already mentioned. The rest of these theses are ignored, and some of them are even by implication contradicted, when he engages in actual historical work. Perhaps the historical work performed by him is none the worse on that account. The chief aim of the historical portion of the first volume is to trace the working of the protective spirit in its political form, and to show its civil tendencies. France, the most civilized country in which that spirit is very powerful, is chosen as the field of illustration, and the history of the intellect and policy of France is laid before us in outline, and compared and contrasted with that of England, the development of which is held to have been comparatively spontaneous and normal. The first chapter of the second volume gives a general view of the history of the Spanish mind from the 5th to the middle of the 19th century, designed to show why the protective spirit has prevailed in Spain in a religious form, and how it has isolated the Spanish nation from the rest of the world, weakened and degraded it, and hitherto frustrated all efforts at improvement. The other four chapters are designed to explain what Mr Buckle supposes to be the largest and most important fact in the history of Scotland, —the combination in its people of liberality in politics with illiberality in religion. In order to accomplish the explanation it is found necessary to argue that the Scottish Reformation was the work of the nobles, animated by hostility to the Roman Catholic priesthood; that the Protestant clergy, owing to being despised by the governing class, united themselves with the people, advocated democratic principles, and, favoured by the course of events, acquired an immense authority, the result of which was the general prevalence of extreme religious bigotry; that the Scotch philosophy of the 18th century, although a reaction against the theological spirit of the 17th, retained the theological method; and that, owing to its deductive character, that philosophy has been inaccessible to the average intellect of the nation, and powerless to free it

from the grasp of superstition. On the proof of these positions Buckle lavished labour, learning, and ingenuity, and, it will be generally admitted, attained some considerable results. But the results were by no means so great or certain as he himself imagined. Few competent judges will deny that, in regard alike to France and Scotland, he overlooked influences which had been as powerful in shaping the characters of these nations as those on which he laid exclusive stress. No explanation of French history can be satisfactory which does not attach due weight to the series of events by which the unity of France was built up, and which only begins after that unity was completed; no explanation of Scottish history can be satisfactory which slurs over the wars with England. The French Revolution was, as Buckle represents it, a reaction against the protective spirit,—but it was a great deal more, and that he did not see; the Scottish Reformation was due in some measure to the antagonism between the nobility and priesthood, as he has amply shown, but he might easily have still more amply shown that it was very far from wholly due to it. To some extent the Scotch philosophy of the 18th century was a reaction against the theological spirit of the 17th, as he saw; but to a much greater extent it was a natural development of British and even European thought, which he should not have overlooked. That either the Scottish philosophy or the Scottish intellect was essentially deductive he wholly failed to make out, and would never have tried to make out, had it not been that his views as to the difference between induction and deduction were strangely vague and confused. Hume was not as deductive as Hobbes. Adam Smith, at least as a political economist, was less deductive than Malthus and Ricardo. Black was less so than Dalton and Davy. To say that deduction is a prominent characteristic of Hutcheson, Reid, or Dugald Stewart, is glaringly contrary to fact. If their writings show any particularly Scottish trait, it is Scottish caution manifesting itself in suspicion of deduction.

Buckle had a high ideal of the historian's duties, and he laboriously endeavoured to realize it; but he fancied himself far more successful in the attempt than he really was, and greatly underrated what had been accomplished by others. He brought a vast amount of information from the most varied and distant sources to confirm his opinions, and the abundance of his materials never perplexed or burdened him in his argumentation, but examples of well-conducted historical inductions are rare in his pages. He sometimes altered and contorted the facts; he very often unduly simplified his problems; he was very apt when he had proved a favourite opinion true to infer it to be the whole truth. His intellect was comprehensive and vigorous, but neither classically cultured nor scientifically disciplined; it was amazingly stored with facts, but not rich in ideas; it was ambitious in aspiration, confident to excess in its own powers, and exceptionally unconscious of where its knowledge ceased and its ignorance began. It was deficient in imagination, poetical feeling, and sympathy. Hence Buckle was narrow and harsh in his judgments on certain great periods of time and large classes of men, on antiquity and the Middle Ages, on the clergy and statesmen, on heroes and martyrs. But he was fearlessly honest according to his lights, and gave expression to the most distasteful of his opinions with a manly openness. He paid great attention to his style, and it has been pronounced, by an eminently competent judge, "equal to the subject, precise enough for the demands of science, full, flowing, and flexible enough for every purpose of eloquence. Lucid when the business of the writer is to state, explain, or illustrate, it ascends, when anger at the oppressor or sympathy with the oppressed call upon it, to tones worthy of Edmund Burke himself denouncing the corruptions of England or the wrongs of India."

BUCKWHEAT, the seeds of various species of *Fagopyrum*, chiefly *F. esculentum*, a herbaceous plant, native of central Asia, but cultivated in Europe on account of its seeds. The seeds, as enclosed in their dark brown tough rind, are three-sided in form, with sharp angles, similar in shape to beech-mast, whence their name from the German *Buchweizen*, beechwheat. Buckwheat is grown in Great Britain only to supply food for pheasants and to feed poultry, which devour the seeds with avidity. In the northern countries of Europe, however, the seeds are employed as human food, chiefly in the form of cakes, which when baked thin have an agreeable taste, with a darkish somewhat violet colour. The meal of buckwheat is also baked into crumpets, as a favourite dainty among Dutch children, and in the Russian army buckwheat groats are served out as part of the soldiers' rations, which they cook with butter, tallow, or hemp-seed oil. Buckwheat is also used as food in the United States; and by the Hindus it is eaten on "bart" or fast days, being one of the phalahas or lawful foods for such occasions. When it is used as food for cattle the hard sharp angular rind must first be removed. As compared with the principal cereal grains, buckwheat is poor in nitrogenous substances and fat; but the rapidity and ease with which it can be grown render it a fit crop for very poor badly tilled land. According to Payen it contains—nitrogenous matter 13·10 per cent., starch 64·90, fat 3·00, water 13·00, cellulose and ash 6·00. An immense quantity of buckwheat honey is collected in Russia, bees showing a marked preference for the flowers of the plant. A dye-stuff is obtained from the leaves of a species of buckwheat, *Polygonum tinctorium*, which may be used for producing a yellow or olive colour on cotton, according to the mordant employed.

BUDA (German, OFEN), a royal free town of the kingdom of Hungary, is situated in 47° 29′ 10″ N. lat. and 19° 2′ 55″ E. long., on the right bank of the Danube, opposite the capital Pesth, with which it has been united since 1849 by a suspension bridge of much beauty, 1227 feet long and 39 feet wide. The nucleus of the town is the "fortress," which occupies an oblong elevation of porphyry rock, not unlike the Acropolis of Athens. It contains the royal palace, the mansions of Counts Sandor, Teleki, and Erdödy, the residence of the governor in command, the arsenal, and several buildings for official purposes. The palace includes the court church—where the regalia of Hungary are preserved, a picture gallery, and a library. Around this central portion there have grown up various suburbs, known respectively as the Wasserstadt, the Landstrasse, the Neustift, the Christinenstadt, and the Taban or Rascian town, the last of which derives its name from its Servian inhabitants, who are mainly vineyard owners. In the Wasserstadt are the church of St Anne and Elizabeth, and the military hospital; in Christinenstadt, the Horvath gardens, with the summer theatre, and the large country-house of Count Caraccioli; and in Old Buda are the royal barracks, part of which was once the monastery of

Mariazell. There are in the town upwards of fifteen churches, as well as several convents, and a Jewish synagogue. The educational establishments include a gymnasium of the highest class, an upper commercial school, five normal institutions, a school of design, a school of music, and about sixteen schools of lower grade. There is also an observatory in the town. Buda has long been celebrated for its mineral baths, which are five in number. The Bruckbad and the Kaiserbad were both founded by the Turks, and the buildings retain traces of Turkish occupation. The temperature of the water is about 118° Fahr. The town is commanded by the eminences known as the Spiessberg or Nap Hegy, and the Blocksberg or Gellert Hegy, the latter of which is crowned by a citadel. The industry of Buda comprises the making of cannon, type-founding, silk-weaving, coach-building, and the manufacture of majolica, copper wares, and gunpowder. A somewhat active trade is carried on in the red wine produced in the neighbouring vineyards, and Old Buda is the seat of a good deal of river traffic. The Danube Steam-Navigation Company have a considerable establishment there, in which a number of their vessels are built. In 1869 the population of the commune was 53,988. Old Buda was known to the Romans for its mineral springs; but the modern town dates only from the Middle Ages. In 1247 King Bela built a castle, which was originally regarded as belonging to Pesth; but the town which gradually gathered round it soon acquired an independent importance. In 1526 it was captured by the Turks, and in their hands became a place of pilgrimage, as well as an important military post. In 1686 it was wrested from them by Charles of Lorraine. During the Hungarian wars of the present century it played a distinguished part. In January 1849 the fortress was seized by the Austrian general Windischgrätz; but in May it was taken by storm by the Hungarians under Görgey. On their departure the Russians took possession, but shortly afterwards handed the place over to the Austrian forces.

BUDÆUS, or BUDÉ, GUILLAUME (1467–1540), descended of an ancient and illustrious family, was a native of Paris. At an early age he was sent to the schools of Paris, and afterwards to the university of Orleans to study law. He passed his time, however, in idleness, and being heir to a large fortune, was left, on his return to Paris, to follow his passion for gaming and pleasure. It was only when the fire of youth began to cool that he was seized with an irresistible passion for study; and having disposed of his hunting equipage, he abandoned business of every description, and applied himself wholly to literature. Without assistance, he made rapid progress, particularly in the Latin and Greek languages. The work which gained him greatest reputation was his treatise *De Asse*, the first edition of which was published at Paris in 1514. He was held in high esteem by Francis I., who was persuaded by him and by Du Bellay to found the Royal College of France, for teaching languages and sciences. He was sent by the king to Rome as ambassador to Leo X., and in 1522 was made master of requests. He died in Paris in 1540. Of his works, printed at Basel in 4 vols. folio in 1557, the most important is the *Commentarii Græcæ Linguæ*, which first appeared in 1529.

BUDAUN, a district of British India, in the Rohilkhand division, under the jurisdiction of the Lieutenant-Governor of the North-Western Provinces, lies between 27° 38′ and 28° 29′ N. lat., and 78° 21′ and 79° 35′ E. long., and is bounded on the N. by the British district of Moradabad, on the N.E. by the district of Bareilly, on the S.E. by that of Sháhjahánpur, on the S. by Farukhabad and Mainpuri, and on the west by Aligarh and Bulandshahr. The country is low, level, and is generally fertile, and watered by the Ganges, the Rámganga, the Sot or Yarwafádár, and the Maháwá. The area is 2004·84 square miles, of which 1376·94 square miles are under cultivation, 382·54 square miles cultivable but not actually under cultivation, and the rest uncultivable waste. The district population in 1872 amounted to 934,348 souls, residing in 193,589 houses, and inhabiting 2364 villages. Of the total population, 794,532 or 85·1 per cent. were Hindus, 139,687 or 14·9 per cent. Mahometans, 129 Christians and others of unspecified religion. Rice, wheat, sugar-cane, cotton, pulses, oil-seeds, and varieties of millet form the principal agricultural products of Budaun. The chief routes through the district are the roads from Farukhabad to Moradabad, from Agra to Bareilly, from Aligarh to Moradabad, and from Delhi to Bareilly. In 1870–71, the total revenue amounted to £130,424, of which £111,722 or 85 per cent. was derived from the land. In 1872–73 Budaun district contained 303 schools, attended by 4848 pupils. The following towns in the district have upwards of 5000 inhabitants:—Budaun, the administrative headquarters,—area, 335 acres, population 33,322; Islámnagar, population 5424; Ujháni, 7656; Sahaswán, 17,063; Bilsi, 5282; Alápur, 5347. Budaun district was ceded to the British Government in 1801 by the Nawab of Oudh. During the mutiny of 1857, the people of Budaun sided with the rebels, and the European officer in charge of the district only saved his life by flight.

BUDDÆUS, JOHN FRANCIS (1667–1729), a celebrated Lutheran divine, and one of the most learned men Germany has produced, was born at Anklam, a town of Pomerania, where his father was minister. He studied with great distinction at Greifswald and at Wittenberg, and having attained to eminence in languages, theology, and history, was appointed Greek and Latin professor at Coburg, afterwards professor of ethical science and politics in the university of Halle, and at length, in 1705, professor of divinity at Jena, where, after having acquired a very great reputation, he died in 1729.

His principal works are,—A large historical German Dictionary, Leipsic, 1709, folio; *Historia Ecclesiastica Veteris Testamenti*, Halle, 1709, 4 vols. 4to; *Elementa Philosophiæ Practicæ, Instrumentalis, et Theoreticæ*, 3 vols. 8vo, which has passed through a great number of editions; *Selecta Juris Naturæ et Gentium*, Halle, 1704, 8vo; *Miscellanea Sacra*, Jena, 1727, 3 vols. 4to; and *Isagoge Historico-Theologica ad Theologiam Universam, singulasque ejus partes*, 2 vols. 4to.

BUDDHISM

BUDDHISM is the name of a religion which formerly prevailed through a large part of India, and is now professed by the inhabitants of Ceylon, Siam, and Burma (the southern Buddhists), and of Nepāl, Tibet, China, and Japan (the northern Buddhists).[1] It arose out of the philosophical and ethical teachings of Siddhārtha Gautama, the eldest son of Suddhōdana, who was rāja in Kapilavastu, and chief of the tribe of the Sākyas, an Aryan clan seated during the 5th century B.C. on the banks of the Kohāna, about 100 miles N. of the city of Benāres, and about 50 miles S. of the foot of the Himālaya Mountains.

We are accustomed to find the legendary and the miraculous gathering, like a halo, around the early history of religious leaders, until the sober truth runs the risk of being altogether neglected for the glittering and edifying false-

[1] The number of Buddhists is now probably about 450,000,000. Professor Max Müller, *Chips from a German Workshop*, i. p. 214.

hood. Buddha has not escaped the fate which has befallen the founders of other religions; and as late as the year 1854 the late Professor Wilson of Oxford read a paper before the Royal Asiatic Society of London in which he maintained that the supposed life of Buddha was a myth, and "Buddha himself merely an imaginary being." No one, however, would now support this view; and it is admitted that, under the mass of miraculous tales which have been handed down regarding him, there is a basis of truth already sufficiently clear to render possible an intelligible history, which will become clearer and clearer as older and better authorities are made accessible.

The chief sources of our at present available information regarding the life of Buddha are—1, The *Manual of Buddhism*, published in 1860 by the Rev. R. Spence Hardy, compiled from various *Sinhalese* sources; 2, The translation into English (published by Bishop Bigandet in Rangoon in 1858 under the title *Legend of the Burmese Buddha*) of the translation into *Burmese* of a *Pāli* work called by Bigandet *Mallalingara-Wouttoo*, of unknown author and date; 3, The original *Pāli* text of the Jātaka commentary, written in Ceylon in the 5th century A.D., edited in 1875 by Mr Fausböll of Copenhagen (this is our best authority); 4, Mr Beal's recently published translation into English (under the title *The Romantic Legend of Sakya Buddha*) of a translation into *Chinese*, made in the 6th century A.D., of a *Sanskrit* work, called *Abhinishkramana Sūtra*; 5, A *Sanskrit* work called the *Lalita Vistara*, undoubtedly very old, but of unknown author or date, the text of which has appeared in the *Bibliotheca Indica* in Calcutta, and a translation through the Tibetan into French by M. Foucaux in Paris (1848). The first three books represent the views of the southern Buddhists, whose sacred books are in Pāli, and last the two those of the northern Buddhists, whose sacred books are in Sanskrit. The former are much the more reliable and complete, the latter being inflated to a great length by absurd and miraculous legends, the kernel of fact at the centre of which agrees in the main with the account found in the former. These have their miraculous incidents too, the relation of the Sanskrit sources to the Pāli resembling in many respects that of the apocryphal gospels to the New Testament.

As there has been little or no intercommunication between the two churches since the 3d century B.C., great reliance may reasonably be placed on those statements in which they agree; not indeed as a proof of the actual facts of the Buddha's biography, but as giving us the belief of the early Buddhists concerning it. It is to be regretted that the books we have to compare are, as yet, of so comparatively modern a date; but, after the respective canons had once been fixed, it is not likely that translators would deviate very materially from the text of the biographies, so sacred to them, with which they had to deal. The southern canon—usually called the Tripitaka or three collections—was finally determined about 250 B.C., at the Council of Pātaliputra on the Ganges, held under the auspices of the Emperor Asoka the Great; and the northern about the commencement of our era at the Council of Jālandhara, in Kashmir, held under Kanishka, a powerful Indo-Scythian monarch. To the former belongs the Buddhavansa, or History of the Buddhas, on which, together with its commentary, our three southern accounts are chiefly based; to the latter belongs the Lalita Vistara, the last of the authorities mentioned above.

At the end of this article will be found a description of those parts of the canon as yet published; for what is known of the contents of the unpublished parts the student is referred, for the northern, to B. H. Hodgson's *Essays*, pp. 17 *et seq.* and 36 *et seq.*; to Csoma Körösi in the *Asiatic Researches*, vol. xx.; Burnouf, *Intr.*, 34–68; and Köppen, ii. 279; for the southern to Hardy's *Eastern Monachism* (1850), p. 166 *et seq.*, and to M. Barthélemy St-Hilaire's papers in the *Journal des Savants* for Feb. and March 1866.

Part I.—The Life of Gautama Buddha.

At the end of the 6th century B.C. the Āryan tribes from the Panjāb had long been settled on the banks of the Ganges; the pride of race had put an impassable barrier between them and the conquered aborigines; the pride of birth had built up another between the chiefs or nobles and the mass of the Āryan people; and the superstitious fears of all yielded to the priesthood an unquestioned and profitable supremacy; while the exigencies of occupation and the ties of family had further separated each class into smaller communities, until the whole nation had became gradually bound by an iron system of caste. *The old child-like joy in life so manifest in the Vedas had* died away; the worship of nature had developed or degenerated into the worship of new and less pure divinities; and the Vedic songs themselves, whose freedom was little compatible with the spirit of the age, had faded into an obscurity which did not lessen their value to the priests. The country was politically split up into little principalities, each governed by some petty despot, whose interests were not often the same as those of the community. A convenient belief in the doctrine of the transmigration of souls satisfied the unfortunate that their woes were the natural result of their own deeds in a former birth, and though unavoidable now, might be escaped in a future state of existence by present liberality to the priests. While hoping for a better fate in their next birth, the oppressed people turned for succour and advice in this to the aid of astrology and witchcraft—a belief in which seems to underlie all religions, and is only just dying out among ourselves. The philosophy of the day no longer hoped for an immortality of the soul, but looked for a release from the misery which it found inseparable from life, in a complete extinction of individual existence. The inspiriting wars against the enemies of the Āryan people, the infidel deniers of the Āryan gods, had given place to a succession of internecine feuds between the chiefs of neighbouring clans; and in literature an age of poets had long since made way for an age of commentators and grammarians, who thought that the old poems must have been the work of gods. But the darkest period was succeeded by the dawn of a reformation; travelling logicians were willing to maintain theses against all the world; whilst here and there ascetics strove to raise themselves above the gods, and hermits earnestly sought for some satisfactory solution of the mysteries of life. These were the teachers whom the people chiefly delighted to honour; and though the ranks of the priesthood were for ever firmly closed against intruders, a man of lower caste, a Kshatriya or Vaisya, whose mind revolted against the orthodox creed, and whose heart was stirred by mingled zeal and ambition, might find through these irregular orders an entrance to the career of a religious teacher and reformer.

Sākyas, and who from their well-watered rice-fields could see the giant Himālayas looming up against the clear blue of the Indian sky. Their supplies of water were drawn from the River Rohini, the modern Kohāna; and though the use of the river was in times of drought the cause of disputes between the Sākyas and the neighbouring Koliyans, the two clans were then at peace; and two daughters of the rāja of Koli, which was only 11 miles east of Kapilavastu, were the principal wives of Suddhōdana. Both were childless, and great was the rejoicing when, in about the forty-fifth year of her age, the elder sister, Mahāmāyā, promised her husband a son. In due time she started with the intention of being confined at her parent's home, but the party halting on the way under the shade of some lofty satin trees, in a pleasant garden called Lumbini on the river side, her son, the future Buddha, was there unexpectedly born. The marvellous stories which gathered round the belief in his voluntary incarnation and immaculate conception, the miracles at his birth, the prophecies of the aged saint at his formal presentation to his father, and how nature altered her course to keep a shadow over his cradle, whilst the sages from afar came and worshipped him, will be referred to hereafter under the head of later Buddhism.

He was in after years more generally known by his family name of Gautama, but his individual name was Siddhārtha. When he was nineteen years old he was married to his cousin Yasodharā, daughter of the Koliyan rāja, and gave himself up to a life of Oriental luxury and delight. Soon after this, according to the southern account, his relations formally complained to the rajā that his son lived entirely for pleasure without learning anything, and asked what they should do under such a leader if war arose. Gautama, hearing of this, is said to have appointed a day for a trial of his prowess, and by defeating all his competitors in manly exercises, and surpassing even his teachers in knowledge, to have won back the good opinion of the disaffected Sākyas. This is the solitary record of his youth; we hear nothing more till, in his twenty-ninth year, it is related that, driving to his pleasure-grounds one day, he was struck by the sight of a man utterly broken down by age, on another occasion by the sight of a man suffering from a loathsome disease, and some months after by the horrible sight of a decomposing corpse. Each time his charioteer, whose name was Channa, told him that such was the fate of all living beings. Soon after he saw an ascetic walking in a calm and dignified manner, and asking who that was, was told by his charioteer the character and aims of the ascetics. The different accounts of this vary so much as to cast great doubts on their accuracy.[1] It is, however, clear from what follows, that about this time the mind of the young Rājput must, from some cause or other, have been deeply stirred. Many an earnest heart full of disappointment or enthusiasm has gone through a similar struggle, has learnt to look upon all earthly gains and hopes as worse than vanity, has envied the calm life of the cloister, troubled by none of these things, and has longed for an opportunity of entire self-surrender to abstinence and meditation.

Subjectively, though not objectively, these visions may be supposed to have appeared to Gautama. After seeing the last of them, he is said to have spent the afternoon in his pleasure-grounds by the river side; and having bathed, to have entered his chariot in order to return home. Just then a messenger arrived with the news that his wife Yasodharā had given birth to a son, his only child. "This," said Gautama quietly, "is a new and strong tie I shall have to break." But the people of Kapilavastu were greatly delighted at the birth of the young heir, the rāja's only grandson. Gautama's return became an ovation; musicians preceded and followed his chariot, while shouts of joy and triumph fell on his ear. Among these sounds one especially attracted his attention. It was the voice of a young girl, his cousin, who sang a stanza, saying, "Happy the father, happy the mother, happy the wife of such a son and husband." In the word "happy" lay a double meaning; it meant also freed from the chains of existence, delivered, *saved*.[2] Grateful to one who, at such a time, reminded him of his highest hopes, Gautama, to whom such things had no longer any value, took off his collar of pearls and sent it to her. She imagined this was the beginning of a courtship, and began to build day-dreams about becoming his principal wife, but he took no further notice of her and passed on. That evening the dancing-girls came to go through the Nātch dances, then as now so common on festive occasions in many parts of India; but he paid them no attention, and gradually fell into an uneasy slumber. At midnight he awoke; the dancing-girls were lying in the ante-room; an overpowering loathing filled his soul. He arose instantly with a mind fully made up,—"roused into activity," says the Sinhalese chronicle, "like a man who is told that his house is on fire."[3] He called out to know who was on guard; and finding it was his charioteer Channa, he told him to saddle his horse. While Channa was gone Siddhārtha gently opened the door of the room where Yasodharā was sleeping, surrounded by flowers, with one hand on the head of their child. He had hoped to take the babe in his arms for the last time before he went, but now he stood for a few moments irresolute on the threshold looking at them. At last the fear of awakening Yasodharā prevailed; he tore himself away, promising himself to return to them as soon as his mind had become clear, as soon as he had become a Buddha,—*i.e.* Enlightened,—and then he could return to them not only as husband and father, but as teacher and saviour. It is said to have been broad moonlight on the full moon of the month of July, when the young chief, with Channa as his sole companion, leaving his father's home, his wealth and power, his wife and child behind him—went out into the wilderness to become a penniless and despised student, and a homeless wanderer. This is the circumstance which has given its name to the Sanskrit work, the fourth of those mentioned above, of which Mr Beal has given us a version through the Chinese, the *Mahābhinishkramana Sūtra*, or *Sūtra of the Great Renunciation*.

Next is related an event in which we may again see a subjective experience given under the form of an objective reality. Māra, the great tempter, appears in the sky, and urges Gautama to stop, promising him, in seven days, a universal kingdom over the four great continents if he will but give up his enterprise. When his words fail to have any effect, the tempter consoles himself by the confident hope that he will still overcome his enemy, saying, "Sooner or later some lustful or malicious or angry thought must arise in his mind; in that moment I shall be his master;" and from that hour, adds the Burmese chronicle, "as a

[1] They all agree in making the four visions phantoms, saying that it was an angel who appeared under these forms, and was visible only to Buddha and his charioteer, who was specially inspired to say what he did. Some make all four visions appear on the same day, others on different days, and there are other discrepancies. Compare *Jātaka*, p. 59, with Bigandet, pp. 34, 35; Hardy, *M. B.*, pp. 153–155; Beal, pp. 107–111, and 115–123.

[2] The word used was *nibbuta*, the past participle passive of a verb, from the root of which is derived the word *nirvāna*; in Pāli, *nibbāna*. *Jātaka*, p. 60.

[3] Hardy, *M. B.*, p. 157; but compare Bigandet, p. 39, and *Jātaka*, p. 61, lines 28, 29. Beal, p. 131, gives a similar expression on a subsequent occasion, p. 165.

shadow always follows the body, so he too from that day always followed the Blessed One, striving to throw every obstacle in his way towards the Buddhahood."[1] Gautama rides a long distance that night, only stopping at the banks of the Anomā beyond the Koliyan territory. There, on the sandy bank of the river, at a spot where later piety erected a dāgaba (a solid dome-shaped relic shrine), he cuts off with his sword his long flowing locks, and taking off his ornaments, sends them and the horse back in charge of the unwilling Channa to Kapilavastu. The next seven days were spent alone in a grove of mango trees near by, whence the ascetic walks on to Rājagriha, the capital of Magadha, and residence of Bimbisāra, one of the then most powerful rulers in the valley of the Ganges. He was favourably received by the rāja, a friend of his father's; but though asked to do so, he would not as yet assume the responsibilities of a teacher. He attached himself first to a Brahman sophist named Alāra, and afterwards to another named Udraka, from whom he learnt all that Hindu philosophy had then to teach.[2] Still unsatisfied, he next retired to the jungle of Uruvela, on the most northerly spur of the Vindhya range of mountains, and there for six years, attended by five faithful disciples, he gave himself up to the severest penance and self-torture, till his fame as an ascetic spread in all the country round about "like the sound," says the Burmese chronicle "of a great bell hung in the canopy of the skies."[3] At last one day, when he was walking in a much enfeebled state, he felt on a sudden an extreme weakness, like that caused by dire starvation, and unable to stand any longer he fell to the ground. Some thought he was dead, but he recovered, and from that time took regular food and gave up his severe penance, so much so that his five disciples soon ceased to respect him, and leaving him went to Benares.

There now ensued a second struggle in Gautama's mind, described in both southern and northern accounts with all the wealth of poetry and imagination of which the Indian mind is master. The crisis culminated on a day, each event of which is surrounded in the Buddhist accounts with the wildest legends, on which the very thoughts passing through the mind of Buddha appear in gorgeous descriptions as angels of darkness or of light. To us, now taught by the experiences of centuries how weak such exaggerations are compared with the effect of a plain unvarnished tale, these legends may appear childish or absurd, but they have a depth of meaning to those who strive to read between the lines of such rude and inarticulate attempts to describe the indescribable. That which (the previous and subsequent career of the teacher being borne in mind) seems to be possible and even probable, appears to be somewhat as follows.

Disenchanted and dissatisfied, Gautama had given up all that most men value, to seek peace in secluded study and self-denial. Failing to attain his object by learning the wisdom of others, and living the simple life of a student, he had devoted himself to that intense meditation and penance which all philosophers then said would raise men above the gods. Still unsatisfied, longing always for a certainty that seemed ever just beyond his grasp, he had added vigil to vigil, and penance to penance, until at last, when to the wondering view of others he had become more than a saint, his bodily strength and his indomitable resolution and faith had together suddenly and completely broken down. Then, when the sympathy of others would have been most welcome, he found his friends falling away from him, and his disciples leaving him for other teachers. Soon after, if not on the very day when his followers had left him, he wandered out towards the banks of the Nairanjara, receiving his morning meal from the hands of Sujātā, the daughter of a neighbouring villager, and set himself down to eat it under the shade of a large tree (a *Ficus religiosa*), to be known from that time as the sacred Bo tree or tree of wisdom. There he remained through the long hours of that day debating with himself what next to do. All his old temptations came back upon him with renewed force. For years he had looked at all earthly good through the medium of a philosophy which taught him that it, without exception, contained within itself the seeds of bitterness, and was altogether worthless and impermanent; but now to his wavering faith the sweet delights of home and love, the charms of wealth and power, began to show themselves in a different light, and glow again with attractive colours. He doubted, and agonized in his doubt; but as the sun set, the religious side of his nature had won the victory, and seems to have come out even purified from the struggle. He had become clear in his mind, the Buddha, the Enlightened One, and had determined in the main to adhere to his belief; but from that night he not only did not claim any merit on account of his self-mortification, but took every opportunity of declaring that from such penances no advantage at all would be derived. All that night he is said to have remained in deep meditation under the Bo tree, and the orthodox Buddhists believe that for seven times seven nights and days he continued fasting near the spot, when the archangel Brahmā came and ministered to him. As for himself, his heart was now fixed,—his mind was made up,—but he realized more than he had ever done before the power of temptation, and the difficulty, the almost impossibility, of understanding and holding to the truth. For others subject to the same temptations, but without that earnestness and insight which he felt himself to possess, faith might be quite impossible, and it would only be waste of time and trouble to try to show to them "the only path of peace." To one in his position this thought would be so very natural, that we need not hesitate to accept the fact of its occurrence as related in the books. It is quite consistent with his whole career that it was love and pity for humanity—otherwise, as it seemed to him, helplessly doomed and lost—which at last overcame every other consideration, and made Gautama resolve to announce his doctrine to the world.

Gautama had intended to proclaim his new gospel first to his old teachers Alāra and Udraka, but finding that they were dead, he determined to address himself to his former five disciples, and accordingly went to the Deer-forest near Benares where they were then living. An old

[1] The word Buddha is always used in the Pāli texts as a title, not as a name. The historical Buddha, the Gautama of this article, taught that he was one of a long series of Buddhas, who appear at intervals in the world, and all teach the same doctrine. After the death of each Buddha his religion flourishes for a time and then decays, and is at last completely forgotten; until a new Buddha appears, who again preaches the lost truth (or Dharmma). The next Buddha will be Maitreya Buddha, the Buddha of kindness. A short account of each of the twenty-four legendary Buddhas who immediately preceded Gautama will be found in the *Jātaka*, pp. 2–44. See also Mahāvansa, p. 1; Hardy, *M. B.*, p. 49, *et seq.*

[2] The question of the relation between Buddhism and Hindu philosophy is one of extreme interest, but also of extreme difficulty. Except in its elementary principles Buddhist philosophy is at present very little understood; and our knowledge of the Hindu systems is derived from text books, all of which are probably post-Buddhistic, and are ascribed to authors of whom absolutely nothing is known. It seems clear that before the time of Buddha there was much philosophical activity in Northern India, and that his system and that of the six orthodox Hindu sects grew up side by side. Many of the technical terms are common to Buddhism and to one or more of the other systems, of which the Sānkhya and the Yoga, ascribed to Kapila and Patanjali respectively, come the nearest to Buddhism in their general views. A popular account of the six systems will be found in Professor Monier Williams's *Indian Wisdom*, pp. 48–154, and the student who wishes for further information is referred to the authorities there quoted. Beal has some interesting notices of Buddha's discussions with Hindu ascetics, pp. 152–161 and 169–177.

[3] Bigandet, p. 49; and compare *Jātaka*, p. 67, line 27.

gāthā or hymn of the northern Buddhists tells us how the Buddha meets, full of his newly-discovered mission, an acquaintance on the way, who, struck with his appearance, asks him what religion it is that makes him so glad and yet so calm. Gautama tells him that he has now become free from all desires, &c. But his acquaintance, apparently not caring much about these details, further asks him where he is going. The reply is striking. "I am now going," says Buddha, "to the city of Benares to establish the *kingdom of righteousness, to give light* to those enshrouded in darkness, and open the gate of immortality to men." His acquaintance only sneers at his high-flown pretensions, asking what he means by all this. The Buddha adds, "I have completely conquered all evil passions, and am no longer tied down to material existence; and I now only live to be the prophet of perfect truth." His acquaintance replies, "In that case, venerable Gautama, your way lies yonder," and turns away in the opposite direction.[1]

Nothing daunted, the new prophet walked on to Benares, and in the cool of the evening went on to the Deer-forest where the five ascetics were living. Seeing him coming, they resolved not to recognize as a superior one who had broken his vows; to address him by his name, and not as "master" or "teacher;" only, he being a Kshatriya, to offer him a seat. He understands their change of manner, calmly tells them not to mock him by calling him "the venerable Gautama;" that they are still in the way of death, where they must reap sorrow and disappointment, whereas he has found the way to salvation and can lead them to it. They object, naturally enough, from a Hindu point of view, that he had failed before while he was keeping his body under, and how can his mind have won the victory now, when he serves and yields to his body. Buddha replies by explaining to them the principles of his new gospel; and it will be necessary here to anticipate somewhat, and explain very briefly what this was, as the narrative will otherwise be difficult to follow.

The Buddhist Way of Salvation.—Everything corporeal is material, and therefore impermanent, for it contains within itself the germs of dissolution. So long as man is bound up by bodily existence with the material world he is liable to sorrow, decay, and death. So long as he allows unholy desires to reign within him, there will be unsatisfied longings, useless weariness, and care. To attempt to purify himself by oppressing his body would be only wasted effort; it is the moral evil of a man's heart which keeps him chained down in the degraded state of bodily life,—of union with the material world. It is of little avail to add virtue to his badness, for so long as there is evil, his goodness will only ensure him for a time, and in another birth, a higher form of material life; only the complete *eradication of all evil* will set him free from the chains of existence, and carry him to the "other side," where he will be no longer tossed about on the waves of the ocean of transmigration. But Christian ideas must not be put into these Buddhist expressions. Of any immaterial existence Buddhism knows nothing. The foundations of its creed have been summed up in the very ancient formula probably invented by its founder, which is called *the Four great Truths.* These are—1, That misery always accompanies existence; 2, That all modes of existence (of men or animals, in earth and heaven) result from passion or desire (tanhā); 3, That there is no escape from existence except by destruction of desire; 4, That this may be accomplished by following the fourfold way to Nirvāna. Of these four stages, called "*the Paths,*" the first is an awakening of the heart. There are few that do not acknowledge that no man can be really called happy, and that men are born to trouble as the sparks fly upwards, but the majority glide through life filling up their time with business or with pleasure, buoyed up with ever-changing hopes in their mad pursuit of some fancied good. When the scales fall from their eyes, when they begin to realize the great mystery of *Sorrow*, that pain is inseparable from existence, and that all earthly good leads to vexation of spirit, when they turn for comfort and for guidance to the Enlightened One, then they may be said to be awake, and to have entered the *first stage* of the Buddhist way of salvation. When the awakened believer has gone further, and got rid, firstly, of all *impure desires*, and then of all *revengeful feelings*, he has reached the second stage; in the third he successively becomes free (1) from *all evil desires*, (2) from *ignorance*, (3) from *doubt*, (4) from *heresy*, and (5) from *unkindliness and vexation.* "As even at the risk of her own life a mother watches over her child, her only child, so let him (the Buddhist saint) exert good-will without measure towards all beings."[2]

The order here observed is very remarkable. The way to be freed from doubt and heresy lies through freedom from impurity and revenge and evil longings of all kinds; or, in other words, if a man awakened to a deep sense of the mystery of sorrow wishes to understand the real facts of existence, wishes to believe not the false or the partly false, but the true altogether, Buddha tells him not to set to work and study, not to torture himself with asceticism or privation, but to purify his mind from all unholy desires and passions; right actions spring from a pure mind, and to the pure in heart all things are open. Again, the first enemy which the awakened believer has to fight against is sensuality, and the last is unkindliness; it is impossible to build anything on a foundation of mire; and the topstone of all that one can build, the highest point he can reach, the point above purity, above justice, above even faith is, according to Buddha, *Universal charity.* Till he has gained that the believer is still bound, he is not free, his mind is still dark; true enlightenment, true freedom are complete only in Love.

The believer who has gone thus far has reached the last stage; he has cut the meshes of ignorance, passion, and sin, and has thus escaped from the net of transmigration; Nirvāna is already within his grasp; he has risen above the laws of material existence; the secrets of the future and the past lie open before him; and when this one short life is over, he will be free for ever from birth with its inevitable consequences, decay, and death. No Buddhist now hopes to reach this stage on earth; but he who has once entered the "paths" cannot leave them; the final perseverance of the saints is sure; and sooner or later, under easier conditions in some less material world, he will win the great prize, and, entering Nirvāna, be at rest for ever.[3]

But to return to the narrative. For reasons too long to be specified here, it is nearly certain that Buddha had a commanding presence, and one of those deep, rich, thrilling

---

[1] Beal, p. 245. Mr Beal translates the first clause, "to turn the wheel of the excellent law;" but the chakra is no ordinary wheel, it is the royal chariot wheel, and the expression rendered "turn," from the root *vrit*, is more exactly "to set rolling onward." A chakravarti is a universal monarch, the wheels of whose chariot roll on unresisted over the known world, and the figure employed in the gāthā undoubtedly means that Buddha was about to set rolling the royal chariot wheel of a universal kingdom of right, or, in other words, to start or found such a kingdom. Compare Beal, p. 244, note, and p. 142; and Childers's *Pāli Dictionary*, s.v., *Dhammacakkam.*

voices which so many of the successful leaders of men have possessed. We know his deep earnestness, and his thorough conviction of the truth of his new gospel. When we further remember the relation which the five students mentioned above had long borne to him, and that they already believed those parts of his doctrine that are most repugnant to our modern feelings,—the pessimist view of life and the transmigration of souls,—it is not difficult to understand that his persuasions were successful, and that his old disciples were the first to acknowledge him in his new character. The later books say that they were all converted at once; but, according to the most ancient Pāli record,—though their old love and reverence had been so rekindled when Gautama came near that their cold resolutions quite broke down, and they vied with each other in such acts of personal attention as an Indian disciple loves to pay to his teacher,—yet it was only after the Buddha had for five days talked to them, sometimes separately, sometimes together, that they accepted in its entirety his plan of salvation.[1]

Gautama then remained at the Deer-forest near Benares until the number of his personal followers was about threescore, and that of the outside believers somewhat greater. The principal among the former was a rich young man named Yasa, who had first come to him at night out of fear of his relations, and afterwards shaved his head, put on the yellow robe,[2] and succeeded in bringing many of his former friends and companions to the teacher, his mother and his wife being the first female disciples, and his father the first lay devotee. It should be noticed in passing that the idea of a priesthood with mystical powers is altogether repugnant to Buddhism; every one's salvation is entirely dependent on the modification or growth of his own inner nature, resulting from his own exertions. The life of a recluse is held to be the most conducive to that state of sweet serenity at which the more ardent disciples aim; but that of a layman, of a believing householder, is held in high honour; and a believer who does not as yet feel himself able or willing to cast off the ties of home or of business, may yet "enter the paths," and by a life of rectitude and kindness ensure for himself a rebirth under more favourable conditions for his growth in holiness.

After the rainy season Gautama called together those of his disciples who had devoted themselves to the higher life, and whom, for want of a better name, we may call monks, and said to them, "Beloved Rahans, I am free from the five passions which, like an immense net, hold men and angels in their power; you too, owing to my teaching, enjoy the same glorious privilege. There is now laid on us a great duty, that of working effectually for men and angels, and gaining for them also the priceless blessing of salvation. Let us, therefore, separate, so that no two of us shall go the same way. Go ye now and preach the most excellent law, explaining every point thereof, unfolding it with diligence and care. . . . For my part I shall go to the village of Sena, near the deserts of Uruwela."[3] Throughout his career Gautama yearly adopted the same plan, collecting his disciples round him in the rainy season, and after it was over travelling about as an itinerant preacher; but in subsequent years he was always accompanied by some of his most attached disciples.

In the solitudes of Uruwela there were at this time three brothers, fire-worshippers and hermit philosophers, who had gathered round them a number of scholars, and enjoyed a considerable reputation as teachers. Gautama settled among them, and after a time they became believers in his system,—the elder brother, Kāsyapa, taking henceforth a principal place among his followers. His first set sermon to his new disciples is related by Bishop Bigandet under the name of the Sermon on the Mount, the subject of which was a jungle-fire which broke out on the opposite hillside. He warned his hearers against the fires of concupiscence, anger, ignorance, birth, death, decay, and anxiety; and taking each of the senses in order he compared all human sensations to a burning flame which seems to be something it is not, which produces pleasure and pain, but passes rapidly away, and ends only in destruction.[4]

Accompanied by his new disciples, Gautama walked on to Rājagriha, the capital of King Bimbisāra, who, not unmindful of their former interview, came out to welcome him. Seeing Kāsyapa, who as the chronicle puts it, was as well known to them as the banner of the city, the people at first doubted who was the teacher and who the disciple; but Kāsyapa put an end to their hesitation by stating that he had now given up his belief in the efficacy of sacrifices either great or small; that Nirvāna was a state of rest only to be attained by a change of heart; and that he had become a disciple of the Buddha. Gautama then spoke to the king on the miseries of the world which arise from passion, and on the possibility of release by following the way of salvation, which has been briefly sketched above. The rāja invited him and his disciples to eat their simple mid-day meal at his house on the following morning; and then presented Gautama with a garden called Veluvana or Bamboo-grove, afterwards celebrated as the place where the Buddha spent many rainy seasons, and preached many of his most complete discourses. There he taught for some time, attracting large numbers of hearers, among whom two, Sāriputra and Moggallāna, who afterwards became conspicuous leaders in the new crusade, then joined the Sangha, or Society, as Buddha's order of mendicants was called.

world and the world that is to come. But, my father, when a man has found a treasure it is his duty to offer the most precious of the jewels to his father first. Do not delay; let me share with you the treasure I have found." Suddhōdana, abashed, took his son's bowl and led him to his house. There the women of the palace came to welcome him, but not Yasodharā, whom he had not seen since he had watched her sleeping in their chamber with their new-born babe by her side on that eventful night now seven long years ago. "I will wait and see," she had said; "perhaps I am still of some value in his eyes; he may ask, or come. I can welcome him better here." Gautama noticed her absence, and remembering, doubtless, that a recluse could not touch or be touched by a woman, he said, "The princess is not yet free from desire as I am; not having seen me so long she is exceeding sorrowful. Unless her sorrow be allowed to take its course, her heart will break. She may embrace me; do not stop her." He then went to her, and when she saw him enter,—not the husband she had mourned so long, but a recluse in yellow robes with shaven head and shaven face,—though she knew it would be so, she could not contain herself, and fell on the ground, and held him by the feet, and wept; then remembering the impassable gulf between them, she rose and stood on one side. The rāja thought it necessary to apologize for her, telling Gautama how entirely she had continued to love him, refusing to enjoy comforts which he denied himself, taking but one meal a day, and sleeping on a hard uncanopied bed. The different accounts often tell us the thoughts of the Buddha on any particular occasion; here they are silent, only adding that he then told a Jātaka story, showing how great had been her virtue in a former birth.[1] And then they parted: she became an earnest hearer of the new doctrines; and when long afterwards the Buddha was induced, much against his inclination, to established an order of female recluses, his widowed wife Yasodharā became one of the first of the Buddhist nuns.

The next day a great festival was to take place to celebrate the marriage of Gautama's half-brother, Nanda. Gautama went to the pavilion and said to Nanda, "the greatest festival after all is the destruction of all evil desires, the life of a recluse, the knowledge of truth, and the attainment of Nirvāna." He then gave him his alms-bowl, and Nanda followed him to the Nigrodha grove where he was staying. On their arrival there Gautama asked him if he would not enter the Society; but Nanda, though tenderly attached to his half-brother, with whom he had been brought up as a play-fellow (Gautama having no brothers of his own), did not yet desire to give up the world. After much persuasion, however, he consented, and became a disciple. A few days afterwards Yasodharā dressed Rāhula, her child and Gautama's, in his best, and told him to go and ask his father for his inheritance. "I know of no father," said the child, "but the rāja. Who is my father?' Yasodharā took him in her arms, and holding him up to the window pointed out to him the Buddha, who was then taking his mid-day meal at the palace. "That monk," she said, "whose appearance is so glorious, is your father; he has four mines of wealth; go to him, and entreat him to put you in possession of *your inheritance.*" Rāhula went up to Gautama and said to him, without fear and with much affection, "My father, how happy I am to be near you." Gautama silently gave him his blessing; but presently, when he rose to go, Rāhula followed him asking for his inheritance. None of the people stopped him, and Gautama still said nothing. When they reached the Nigrodha grove, he called Ṣāriputra, and said, "Beloved disciple, Rāhula is asking for a worldly inheritance which would avail him nothing; I will give him a spiritual inheritance which will not fade away; let him be admitted among us." When Suddhōdana heard this he was exceedingly grieved; he had lost his two sons as far as all worldly hopes were concerned, and now his grandson was taken from him. Full of sorrow he determined to save other parents a similar affliction, and going to Gautama asked him to establish a regulation that no one should in future be admitted to the Society unless he had the consent of his parents. Gautama granted this request, and after some more interviews with his father returned to the Bambu grove at Rājagriha.

Eighteen months had now elapsed since the turning-point *of Gautama's career—his great struggle under the Bo tree.* Thus far all the accounts agree, and follow chronological order. From this time they simply narrate disconnected stories about the Buddha, or the persons with whom he was brought into contact,—the same story being usually found in more than one account, but not often in the same order. It is not as yet possible, except very partially, to arrange chronologically the snatches of biography to be gleaned from these stories. They are mostly told to show the occasion on which some memorable act of Gautama's took place, or some memorable saying was uttered, and are as exact as to place as they are indistinct as to time. It would be impossible within the limits of this article to give any large number of them, but space may be found for one or two.

A merchant from Sūnaparanta having joined the Society was desirous of preaching to his relations, and is said to have asked Gautama's permission to do so. "The people of Sūnaparanta," said the teacher, "are exceedingly violent. If they revile you what will you do?" "I will make no reply," said the mendicant. "And if they strike you?" "I will not strike in return," was the reply. "And if they try to kill you?" "Death is no evil in itself; many even desire it, to escape from the vanities of life, but I shall take no steps either to hasten or to delay the time of my departure." These answers were held satisfactory, and the monk started on his mission.

At another time a rich farmer held a harvest home, and Gautama, wishing to preach to him, is said to have taken his alms-bowl and stood by the side of the field and begged. The farmer, a wealthy Brāhman, said to him, "Why do you come and beg? I plough and sow and earn my food; you should do the same." "I, too, O Brahman," said the beggar, "plough and sow; and having ploughed and sown I eat." "You profess only to be a farmer; no one sees your ploughing, what do you mean?" said the Brahman. "For my cultivation," said the beggar, "faith is the seed, self-combat is the fertilizing rain, the weeds I destroy are the cleaving to existence, wisdom is my plough, and its guiding-shaft is modesty; perseverance draws my plough, and I guide it with the rein of my mind; the field I work in is the law, and the harvest that I reap is the never-dying nectar of Nirvāna. Those who reap this harvest destroy *all the weeds of sorrow.*"

On another occasion he is said to have brought back to her right mind a young mother whom sorrow had for a time deprived of reason. Her name was Kisāgotamī. She had been married early, as is the custom in the East, and had a child when she was still a girl. When the beautiful boy could run alone he died. The young girl in her love for it carried the dead child clasped to her bosom, and went from house to house of her pitying friends asking them to give her medicine for it. But a Buddhist convert thinking

[1] *Jātaka*, 91, 2. These Jātaka stories are most interesting, containing as they do the oldest known versions of many of the nursery songs, and fairy tales, and comic stories, and fables, which are the common property of Europe in the present day. See Fausböll's papers enumerated in the report of the Philological Society for 1875, p. 64.

"she does not understand," said to her, "My good girl, I myself have no such medicine as you ask for, but I think I know of one who has." "Oh, tell me who that is?" said Kisāgotamī. "The Buddha can give you medicine; go to him," was the answer. She went to Gautama; and doing homage to him said, "Lord and master, do you know any medicine that will be good for my child?" "Yes, I know of some," said the teacher. Now it was the custom for patients or their friends to provide the herbs which the doctors required; so she asked what herbs he would want. "I want some mustard-seed," he said; and when the poor girl eagerly promised to bring some of so common a drug, he added, "you must get it from some house where no son, or husband, or parent, or slave has died." "Very good," she said; and went to ask for it, still carrying her dead child with her. The people said, "Here is mustard-seed, take it;" but when she asked, "In my friend's house has any son died, or a husband, or a parent, or slave?" They answered, "Lady! what is this that you say? the living are few, but the dead are many." Then she went to other houses, but one said "I have lost a son," another "We have lost our parents," another "I have lost my slave." At last, not being able to find a single house where no one had died, her mind began to clear, and summoning up resolution she left the dead body of her child in a forest, and returning to the Buddha paid him homage. He said to her, "Have you the mustard seed?" "My lord," she replied, "I have not; the people tell me that the living are few, but the dead are many." Then he talked to her on that essential part of his system, the impermanency of all things, till her doubts were cleared away, she accepted her lot, became a disciple, and entered the "first path."

For forty-five years after entering on his mission Gautama itinerated in the valley of the Ganges, not going further than about 150 miles from Benares, and always spending the rainy months at one spot—usually at one of the vihāras, or homes,[1] which had been given to the Society. In the twentieth year his cousin Ānanda became a mendicant, and from that time seems to have attended on Gautama, being constantly near him, and delighting to render him all the personal service which love and reverence could suggest. Another cousin, Dewadatta, the son of the rāja of Koli, also joined the society, but became envious of the teacher, and stirred up Ajātasatru (who having killed his father, Bimbisāra, had become king of Rājagriha) to persecute Gautama. The account of the manner in which the Buddha is said to have overcome the wicked devices of this apostate cousin and his parricide protector is quite legendary; but the general fact of Ajātasatru's opposition to the new sect and of his subsequent conversion may be accepted. The rival teachers, or sophists, as might be expected, were bitter enemies of the new philosophy, and the Brahmins did all they could to put down a faith which inculcated such dangerous doctrines as the equality within the Society of all ranks and castes, and the possibility of salvation without sacrifices or the assistance of the priests. They instigated certain men to murder Moggallāna, one of the two chief disciples, and made several attempts on the life of the teacher himself; but many of the chiefs, and the great bulk of the common people, are represented, with probable truth, as being uniformly in favour of his doctrine, though the number of those who actually joined the Society was comparatively small.

The confused and legendary notices of the journeyings of Gautama are succeeded by tolerably clear accounts of the last few days of his life. On a journey towards Kusinagara, a town about 120 miles N.N.E of Benāres, and about 80 miles due E. of Kapilavastu, the teacher, being then eighty years of age, had rested for a short time in a grove at Pāwā, presented to the Society by a goldsmith of that place named Chunda. Chunda prepared for the mendicants a mid-day meal, consisting of rice and pork; and it may be noticed in passing how highly improbable it is that any Buddhist would have invented the story of the Buddha's last illness having been brought on by such a cause. He started for Kusi-nagara in the afternoon, but had not gone far when he was obliged to rest, and soon afterwards he said, "Ānanda, I am thirsty;" and they gave him water to drink. Half-way between the two towns flows the River Kukushtā. There Gautama rested again, and bathed for the last time. Feeling that he was dying, and careful lest Chunda should be reproached by himself or others, he said to Ānanda, "After I am gone tell Chunda that he will receive in a future birth very great reward; for, having eaten of the food he gave me, I am about to pass into Nirvāna; and if he should still doubt, say that it was from my own mouth that you heard this. There are two gifts which will be blest above all others, namely, Sujātā's gift before I attained wisdom under the Bo tree, and this gift of Chunda's before I enter the final rest of Nirvāna." After halting again and again the party at length reached the River Hiranyavatī, close by Kusi-nagara, and there for the last time Gautama rested; and lying down under some Sal trees, with his face towards the south, he talked long and earnestly with Ānanda about his burial, and about certain rules which were to be observed by the Society after his death. Towards the end of this conversation, when it was evening, Ānanda broke down and went aside to weep, but Gautama missed him, and sending for him comforted him with the promise of Nirvāna, and repeated what he had so often said before about the impermanence of all things,—"O Ānanda! do not weep; do not let yourself be troubled. You know what I have said; sooner or later we must part from all we hold most dear. This body of ours contains within itself the power which renews its strength for a time, but also the causes which lead to its destruction. Is there anything put together which shall not dissolve? But you, too, shall be free from this delusion, this world of sense, this law of change. Beloved," added he, speaking to the rest of the disciples, "Ānanda for long years has served me with devoted affection. He knows all that should be done; after I am gone listen to his word." And he spoke to them

[1] These houses were at first simple huts, built for the mendicants in some grove of palm trees as a retreat during the rainy season; but they gradually increased in splendour and magnificence till the decay of Buddhism set in. See the authorities quoted in the *Journal of the Royal Asiatic Society* for 1875, p. 22 of the article on "Two Sinhalese Inscriptions."

indifference, are not to be found. O Subhadra! I do not speak to you of things I have not experienced. Since I was twenty-nine years old till now I have striven after pure and perfect wisdom, and following the good path, have found Nirvāna." A rule had been made that no follower of a rival system should be admitted to the Society without four months' probation. So deeply did the words or the impressive manner of the dying teacher work upon Subhadra that he asked to be admitted at once, and Gautama granted his request. Then turning to his disciples he said, "When I have passed away and am no longer with you, do not think that the Buddha has left you, and is not still in your midst. You have my words, my explanations of the deep things of truth, the laws I have laid down for the Society; let them be your guide; the Buddha has not left you." Soon afterwards he again spoke to them, urging them to reverence one another, and rebuked one of the disciples who spoke indiscriminately all that occurred to him. Towards the morning he asked whether any one had any doubt about the Buddha, the law, or the Society; if so, he would clear them up. No one answering, he said, "Beloved mendicants, if you revere my memory, love all the disciples as you love me and my doctrines." Ānanda expressed his surprise that amongst so many none should doubt, and all be firmly attached to the law. But Buddha laid stress on the final perseverance of the saints, saying that even the least among the disciples who had entered the first path only, still had his heart fixed on the way to perfection, and constantly strove after the three higher paths. "No doubt," he said, "can be found in the mind of a true disciple." After another pause he said, "Beloved, that which causes life, causes also decay and death. Never forget this; let your minds be filled with this truth. I called you to make it known to you." These were the last words Gautama spoke; shortly afterwards he became unconscious, and in that state passed away.

Part II.—Early Buddhism.

The accounts of Gautama's cremation and of the distribution of his relics are full of the miraculous, but it seems that the body was burnt with great reverence by the local rājas of Malva. Even before this ceremony had taken place dissensions began to break out in the Society,—one member of the order, Subhadra (not the Brahman mentioned above), having even gone so far as to rejoice that now at last they were free from control, and could not always be told to do this, or not to do that. Struck by this language, the chief disciples began at once to consider the expediency of holding a council, where all points of difference should be definitively set at rest. Chief among the leaders was the aged Kāṣyapa of Uruvela, whose distinguished position before his conversion, and his great learning, were not the only grounds of the respect in which he was held by the infant Society. He had been one of those most intimate with Gautama; so much so, that on one occasion, when walking together and talking of the deepest truths of their belief, the two friends had entered into a more than usual confidence and intercommunion of thought and feeling, and had then changed robes with one another in token of their sympathy and love. Sāriputra and Moggallāna were dead; but Ānanda, the beloved disciple, and Upāli, who though of low caste origin was looked up to in the Society as the greatest authority on points of conduct and discipline, were of one opinion with Kāṣyapa as to the advisability of a council. This was agreed upon; the disciples first separated and went to their homes, and when they met again for the rainy season in that vihāra at Rājagriha, which had been the first gift to the Society, the council was held under the presidency of Kāṣyapa, and with the patronage and assistance of Ajātaṣatru, the powerful rāja of Magadha. The number of believers present was five hundred, but if any discussion took place no tradition of it has survived. We are only told that at each daily sitting of the council which lasted seven months, Ānanda or Upāli repeated some portion of the law, and the whole assembly chanted it after them. A second council is said to have been held one hundred years later in Vaiṣāli, about 70 miles N. of Rājagriha, and another was certainly held about 250 B.C. under the Buddhist emperor Aṣoka, in his capital Pātaliputra, the Palibothra of the Greeks and the modern Patna. There is reasonable ground for belief that the sacred books of the Buddhists at present existing in Ceylon are substantially the same as the canon settled at this last council of Pātaliputra, and it is from these books that the modern accounts on which we are as yet obliged to depend purport to have been and, with some alterations and additions, undoubtedly have been derived. The orthodox Buddhists hold the present canon to be identically the same as that settled at the first council of Rājagriha; but the internal evidence of those parts of the canon which have as yet been published tends to show that they cannot possibly have been composed in their present state immediately after Buddha's death. The date, derived from Ceylon, which is usually assigned to that event is 543 B.C.; but those scholars who have devoted most attention to the point hold this calculation to contain a certain error of about 60 years, and a probable error of 80 to 100 more; so that the date for the death of Buddha would have to be brought forward to 400 B.C., or a few years later. As the date of Aṣoka's council has been determined with certainty to have been within a year or two of 250 B.C., there remains an interval of a century and a half between the first council and the earliest records now accessible to us, an interval amply sufficient for the growth of the supernatural element which they so largely contain. When these records have been published in the original Pāli, it may be possible to decide how far some portions are older than the rest, and how far it is possible to hold that they reproduce any earlier canon; at present we can only claim in the following brief outline to give an account of Buddhism as it existed 150 years after the decease of its founder. But when it is recollected that Gautama Buddha was himself learned in all the learning of his time; that he did not leave behind him a number of deeply simple sayings from which his followers subsequently built up a system, but had thoroughly elaborated a system of his own before his mission began; that during his long career as teacher he had ample time to repeat the principles and details of the system to his disciples over and over again, and to test their knowledge of it; and finally, that his principal disciples were, like himself, accustomed to the subtlest metaphysical distinctions, and trained to that wonderful command of memory which Indian ascetics then possessed,—when these facts are recalled to mind, it will be seen that much more reliance can be placed upon the doctrinal parts of the existing Buddhist canon than upon correspondingly late records of other religions, or on the biographical parts of the Buddhist canon itself.

The Abhidharma or *Philosophy*. Buddhism does not attempt to solve the problem of the ultimate origin of the kosmos.[1] It takes as its own ultimate fact the existence of the material world and of conscious beings living

[1] "When Mālunka asked Buddha whether the existence of the world is eternal or not eternal he made him no reply; but the reason of this was, that it was considered by Buddha as an inquiry that tended to no profit."—Hardy, *M.B.*, 375. Only a Buddha can comprehend how effects are produced by karma, or how the universe was brought into existence.—*Ibid.*, p. 8, note.

within it; and it holds that everything is subject to the law of cause and effect, and that everything is constantly, though perhaps imperceptibly, changing. Though in its principles it anticipates much that modern science has proved, in its details it does not, as might be expected, rise much above the beliefs most current at the time of its origin; but it has formulated them into a hypothetical system sufficiently consistent with itself to have satisfied Buddhists for more than 2000 years, however little consistent with actual truth. Scattered through space, it teaches, there are innumerable circular worlds in sets of three. All of these are exactly similar to our own, in the centre of which rises an enormous mountain, called Māha Meru, which is surrounded by seven concentric circles of rock of an enormous height, and the circle enclosed by the outermost is divided into four quarters, or great continents, part of one of which is Jambudvīpa, the earth in which we live. On the heights of Mahā Meru, and above it and the rock circles, rise the twenty-four heavens, and beneath it and the earth are the eight great hells. These heavens and hells are part of the material world, subject like the rest of it to the law of cause and effect, and the beings within them are still liable to rebirth, decay, and death. Between Mahā Meru and the outmost circle of rocks, the sun, moon, and stars revolve through space; and it is when they pass behind the first circle of rocks that they appear to the inhabitants of Jambudvīpa to set. This world, like each of the others scattered through space, is periodically destroyed by water, fire, or wind, but the sum of the demerits of the beings (men, animals, angels, &c.) who lived within it produces each time a new world, which in its turn is fated to be destroyed. The number of these beings never varies save on those few occasions when one of them either in earth or heaven attains Nirvāna; in every other case, as soon as an individual dies, another is produced under more or less material conditions, according as the sum of the former individual's demerits, minus the sum of its merits, was, at the time of its death, large or small. A belief in such hypotheses seems inconsistent with a fundamental tenet of Buddhist philosophy, that there are only two sources of knowledge, experience, and inference; but the hypotheses themselves are too intimately involved in the whole scheme of Buddhism to leave much doubt as to their having formed part of the original doctrine of its founder. They are, however, scarcely distinctive of Buddhism, but, like the pessimist view of life, are rather modifications of previous beliefs which Buddhism adopted into its system, and from the consequences of which it promised to relieve those who followed out its teachings.[1]

The two ideas of the utter vanity of all earthly good and the inevitable law of rebirth, decay, and death will be seen to lead naturally to the belief in Nirvāna. If life be an evil, and death itself be no delivery from life, it is necessary to go further back to discover the very origin, the seed, so to speak, of existence; and by destroying that to put an end at last to the long train of misery in which we are compelled to go again and again through the same weary round of experiences, always ending in disappointment. This seed of existence Buddhism finds in "Karma," the sum of merit and demerit, which, as each one's demerit is the greater of the two, often comes practically to much the same thing as *sin* or error. It forms the second link in the Buddhist chain of causation,[2] and arises itself from ignorance. Destroy that ignorance which brings with it such a progeny, cut the links of this chain of existence, root out karma with the mistaken cleaving to life, and there will be deliverance at last—deliverance from all sorrow and all trouble in the eternal rest of Nirvāna. Anything less than this would be a mockery of hope; for there is no life outside the domain of transmigration, and by the inevitable law of change that which causes existence of any kind would itself be the cause also of decay, and bring with it after a time the whole chain of evils from which the tired heart of man seeks relief.

To reach this end, to destroy karma, and thus to attain Nirvāna, there is only one way—the fourfold path already explained above, which is also summed up in the Buddhist books in the eight divisions, "right views, right thoughts, right speech, right actions, right living, right exertion, right recollection, and right meditation."[3] By these means ignorance will be overcome and karma destroyed, and after the organized being has been dissolved in death, there will be nothing left to bring about the production of another life. For it must be understood that while Buddhism occasionally yielded so far to popular phraseology as to make use of the word soul, it denies altogether that the word is anything more than a convenient expression, or that it has any counterpart in fact. Birth is not rebirth, but new birth; transmigration of soul becomes a transfer of karma; metempsychosis gives way to metamorphosis. As one generation dies and gives way to another—the heir of the consequences of all its vices and all its virtues, the exact result of pre-existing causes—so each individual in the long chain of life inherits all of good or evil that all its predecessors have done or been, and takes up the struggle towards enlightenment precisely there where they have left it. There is nothing eternal, but the law of cause and effect, and change; the kosmos itself is passing away; even karma can be destroyed; nothing is, everything becomes. And so with this organized life of ours, it contains within itself no eternal germ; it passes away like everything else, there only remains the accumulated result of all its actions. One lamp is lighted at another; the second flame differs from the first, to which it owes its existence. A seed grows into a tree and produces a seed from which arises another tree different from the first, though resulting from it. And so the true Buddhist saint does not mar the purity of his self-denial by lusting after a positive happiness which he himself is to enjoy hereafter. He himself will cease to be, but his virtue will live and work out its full effect in the decrease of the sum of the misery of sentient beings.

A not unnatural confusion has arisen from the fact that the result of each man's actions is held not to be dissipated as it were into many streams, but concentrated together in the formation of one new sentient being. This link of connection between the two otherwise distinct individuals has led to expressions in Buddhist writings which when read by Christians seemed to infer the existence of a soul. Phrases used of those living saints who have entered the fourth path, and have practically attained Nirvāna, have also been supposed by mistake to apply to Nirvāna itself. And when further Nirvāna has been described in glowing terms as the happy seat; the excellent eternal place of bliss, where there is no more death, neither decay; the end of suffering; the home of peace; the other side of the ocean of existence; the shore of salvation; the harbour of refuge; the medicine for all evil; the transcendent, formless, tranquil state, the Truth, the Infinite, the Unspeakable, the Everlasting,—it has been supposed by some European scholars to mean a blissful state in which the soul (?) still exists in an everlasting trance. however, now be no longer any doubt on the point. Spence Hardy and Bigandet find in the modern Sinhalese and Burmese books the same opinion as Alvis and Gogerly and especially Childers have found in the more ancient authorities; and though the modern books of the Northern Buddhists are doubtful, Eugène Burnouf has clearly proved that their older texts contain only the same doctrine as that held in the South. Buddhism does not acknowledge the existence of a soul as a thing distinct from the parts and powers of man which are dissolved at death, and the Nirvāna of Buddhism is simply Extinction.[1]

It will seem strange to many that a religion which ignores the existence of God, and denies the existence of the soul, should be the very religion which has found most acceptance among men, and it is easy to maintain that had Buddha merely taught philosophy, or had he lived in later ages, he might have had as small a following as Comte. Gautama's power over the people arose in a great degree from the glow of his practical philanthropy, which did not shrink in the struggle against the abuses most peculiar to his time; his philosophy and his ethics attracted the masses, from whose chained hands they struck off the manacles of caste, and in leaving the school for the world they insensibly became a religion. But there is no reason to believe that Gautama intended either at the beginning or the end of his career to be the founder of a new religion. He seems to have hoped that the new wine would go into the old bottles, and that all men, not excepting even the Brahmins, would gradually adopt his, the only orthodox, form of the ancient creed. However the question of the historical succession or connection between the different systems of Hindu philosophy be ultimately settled, whether any of them were post-Buddhistic or not, they afford at least sufficient evidence that beliefs very inconsistent with the practical creed of the masses met with little opposition from the priests so long as they were taught only in schools of philosophy; and Buddhist morality was not calculated to excite anger or hatred. But the very means which Gautama adopted to extend and give practical effect to his teaching, while giving it temporary success, led to its ultimate expulsion from India. It was his Society rather than his doctrine, the Sangha rather than the Dharma, which both gave to his religion its practical vitality and excited the active hostility of the Brahmins.

The SANGHA *or Society, the Buddhist Order of Mendicants.*—It was a logical conclusion from the views of life held by Gautama that any rapid progress in spiritual life was only compatible with an ascetic life, in which all such contact with the world as would tend to create earthly desires could be reduced as much as possible; and accordingly from the first he not only adopted such a mode of life for himself but urged it on his more earnest disciples. He contemplated no such division between clergy and laity as obtains in Christian countries, and constantly maintained that there was no positive merit in outward acts of self-denial or penance; but holding that family connections and the possession of wealth or power were likely to prolong that mistaken estimate of the value of things, that clinging to life which was the origin of evil, he taught that to forsake the world was a necessary step towards the attainment of spiritual freedom. Little by little, as occasion arose, he laid down rules for the guidance of those who thus devoted themselves to the higher life, and insensibly as he did so, the Society became more and more like one of the monkish orders which sprung up afterwards in the west. But not even now has the order become a priesthood. It possesses no mystic powers of regeneration or confirmation or absolution from sin; it works no miracles by consecration or by prayer, and its doors are always open alike to those who wish to enter and to those who wish to leave it. In a system which acknowledged no Creator and no God, the monks could never become the only efficient intercessors between man and his Maker; and since salvation was held to be and to depend upon a radical change in man's nature, brought about by his own self-denial and his own self-control, the monks could never obtain power over the keys of heaven and hell. When successive kings and chiefs were allowed to endow the society, not indeed with gold or silver, but with the few necessaries of the monkish life, including lands and houses, it gradually ceased in great measure to be the school of virtue or the most favourable sphere for intellectual progress, and became thronged with the worthless and the idle; but in the time of its founder it undoubtedly contained few besides those who longed under his guidance first to train themselves and then to preach to others the glad tidings of rest; that hope, to us so uninviting and so cold, to them—to whom life, under their glowing sky and under the oppressive weight of tyranny in church and state, was a burden too heavy to be borne—to them so welcome and so sweet, of utter rest in annihilation. For admittance to the Society no other credentials were at first required than the simple wish of the applicant; afterwards on different occasions a few necessary conditions were imposed, the applicant being obliged to state that he was free from contagious disease, consumption, and fits; that he was neither a slave nor a debtor nor a soldier, that is, that he was *sui juris;* and that he had obtained the consent of his parents. At first, also, the candidate was admitted without any ceremony by merely shaving his head, putting on the yellow robes, and leading an ascetic life; afterwards a simple ceremony was adopted, probably identical with that now in use in Ceylon, an excellent account of which has been given in the Journals of the Ceylon Asiatic Society for 1852 and of the Royal Asiatic Society for 1873. At first also there is no mention of any distinction within the ranks of the society; but the preparatory rank of novice was very early introduced, and later on, as the religion became more and more corrupted, the order became more and more subdivided, until in Tibet, in the 14th century, we find a complete episcopal hierarchy.

Rules of the Order.—The most usual names applied in the sacred books to the senior members of the order are Sramana and Bhikshu, and to the novices Sāmanera. The first, from which the third is derived, means one who exerts himself, controls himself; the second means simply a beggar. Self-conquest and poverty, then, were to be the distinguishing characteristics of the "sons of Sākya," but it was not left to them to decide for themselves how far this self-suppression and abstinence were to be carried. The teacher gave a number of rules and directions which have been handed down to us more or less correctly in the Vinaya, the first part of the Buddhist canon, and which are summed up in the "Pātimokkha," a book which, though not included in the canon, cannot be much later than the great council of Asoka, about 250, and is regarded with much reverence by the monks, from its having from time immemorial been ordered to be read twice monthly in every monastery. These rules may be roughly divided into two divisions, those which are obligatory, and those which, not being obligatory, are recommended to such as wish to work out their own salvation to a point further than that attainable by the ordinary rules. And first, as to *food.* No monk can eat solid food except between sunrise and noon, and

[1] On Nirvāna, see Gogerly, *Journal of the R. A. S., Ceylon Branch*, 1867-1870, Part i. p. 130; Alvis, *Buddhist Nirvāna*, Colombo, 1871; Childers, *Pali Dict.*, sub. v., Nirvāna; Burnouf, *Intr.*, 18-20, 78, 83, 155, 516-522, and esp. 589 *et seq.*, and *Lotus*, 355; Hardy's *Eastern Monachism*, 290-309; Bigandet, p. 320-323; Wassilief, *Der Buddhismus*, p. 101. On the other side, Prof. Max Müller, *Buddhaghosha's Parables*, xxxix-xlv.; Mohl, *Journal Asiatique*, 1856, p. 94; and Obry, *Du Nirvâna Bouddhique*, Paris, 1863.

total abstinence from intoxicating drinks is obligatory. The usual mode of obtaining food is for the monk to take his begging-bowl, a brown earthenware vessel, in shape nearly like a soup tureen without its cover, and holding it in his hands, to beg straight from house to house. He is to say nothing, but simply stand outside the hut, the doors and windows of which in India are usually large and open. If anything is put into his bowl he utters a pious wish on behalf of the giver and passes on; if nothing is given he passes on in silence, and thus begs straight on without going to the houses of the rich or luxurious rather than to those of the poor and thrifty. As the food of all classes consisted almost exclusively of some form of curry, the mixture was not so very incongruous, and when enough had been given, the monk retired to his home to eat it, thinking the while of the impermanence and worthlessness of the body which was thus nourished, and of the processes through which the food would have to pass. To express a Buddhist idea in the quaint words of Herbert, "Look on meat, think it dirt, then eat a bit, and say withal, Earth to earth I commit." From the first it was permitted to wealthy or pious laymen to invite one or more monks to take their mid day meal at their houses, and this was frequently done, especially on full moon days; it was also allowed to the laity on special occasions to bring food to the monastery. For the stricter monks further vows are mentioned of abstinence from animal food, of eating the whole meal without rising, of refusing all invitations and all food brought to them, of eating everything in the bowl without leaving or rejecting anything, and so on; but it is doubtful whether they are ever observed now, and they were formerly taken only for a time. Much later a practice sprung up of the order possessing rice fields, letting them out to be cultivated on condition of receiving a share of the produce, and then having their meals cooked at home by some lay follower or even slave.

As regards *residence*, Gautama considered a lonely life in the forest to be the most conducive to self-conquest; but as he himself, after having lived apart from the world, spent his life from the commencement of his prophetic career among men, so from the first the lonely life was adopted only by the most earnest, and that only for a time. The majority of the monks lived in companies in groves or gardens, and very soon the piety of laymen provided for them suitable monasteries, several of which were built even in the lifetime of Buddha. During the fine weather the monks often travelled from place to place, as their teacher did, but during the rainy season they always settled in one spot in or near a town; and near the ancient cities of India have been lately discovered extensive ruins on the site of the monasteries mentioned in the Pāli books. On the other hand, there have been found numerous rock caves, many of which, especially in Ceylon, were evidently meant for solitary hermits, and they often bear inscriptions in the old Pāli character, brought by Aṣoka's son Mahendra to Ceylon in the 3d century B.C.

As regards *clothing*, the monks were to be habited in clothes of no value, put together from cast-off rags; but here again the practice of Buddha himself, and that followed by the large majority of the brethren, was to dress in simple robes of dull orange colour, first torn to pieces and then sewed together again, so as to form two under garments, and one upper garment to cover the whole of the body except the right shoulder. All three are simply lengths of cotton cloth; the two under ones, the antara-vāsaka and the sanghāṭi, being wrapt round the middle of the body, and round the thighs and legs respectively; and the upper one, the uttarāsanga, being first wrapt round the legs and then drawn over the left shoulder. The colour was probably at first chosen as the one regarded with most contempt, because of its being nearly the same as that of very old rags of the common white cotton cloth, and because cloths of that colour were of no value at all for ordinary purposes; but the orange-coloured robes, from their very peculiarity as a sign of the members of the Sangha, soon came to be looked upon as an honour, and were sought after on that account alone; so that the Dhammapada, a collection of ethical verses, one of the books in the Buddhist canon, has to give a warning that those who are not free from sin (*kasāva*) are not worthy of the orange colour (*kāsāva*). In Buddhist countries men's ordinary dress is merely a cloth wrapt round the loins, whereas the monks are to cover the whole body, and are not permitted at any time to lay their robes aside. To do so would be to lay aside their membership of the order, to put on or to put off the robes being current expressions for joining or leaving the Society. Of course no ornaments are allowed, and even the natural ornament of hair is not permitted, complete tonsure being obligatory on all. No monk should possess more than one change of robes, and minute rules in detail are laid down to guard against any brother even by indirect methods taking any steps to procure himself new ones; to provide them spontaneously is the duty and privilege of the laity.

It is scarcely necessary to state that *sexual intercourse*, *theft*, and *murder* entail upon the culprit irrevocable expulsion from the order; while the ease with which the Society could be left provided an escape for those who found the vow of continence too hard to keep. On the vow of *poverty* a few words ought to be said. In his individual right no monk is to possess more than the following eight articles: 1, 2, 3, the three robes mentioned above; 4, a girdle for the loins; 5, an alms-bowl; 6, a razor; 7, a needle; 8, a water-strainer, through which he is to strain all he drinks—not only to remove impurities, but also and chiefly to prevent the accidental destruction of any living creatures. This individual vow of poverty has however been swallowed up by the permission given to the community to possess not only books and other personal property, but even lands and houses. Gautama himself is said to have received such gifts on behalf of the Sangha, which at the time of its expulsion from India must have rivalled in wealth the most powerful orders of the Middle Ages; and in some Buddhist countries at the present day the Society possesses enormous tracts of the most valuable land. But water-drinking celibates, who take only one meal a day, and dress in a simple uniform, could never indulge in unbounded personal luxury. Many members of the order enjoy the fascinating sense of wealth, so completely contrary to all the principles of their religion, and to the precepts laid down by their Teacher for the attainment of spiritual progress; they are often lazy and not seldom avaricious; but in the southern church at least they are not disgraced by gluttony or drunkenness, and have never given way to the weak vanity of dress, or of the pomp and pride of ritual.

which he has not sufficient self-control to reject. Twice a month, when the rules of the order are read, a monk who has broken them is to confess his crime. If it be slight some slight penance is laid upon him, to sweep the courtyard of the wihāra, or to sprinkle dust round the sacred Bo tree, but no inquisitorial questions are put to any one. Charges may be brought against a monk for breach of the ordinances laid down by Buddha, and must then be examined into by a chapter, but none can change or add to the existing law, or claim obedience from any other member of the order, however young.

The *daily life* of the novice should, according to a manual in Sinhalese called *Dina Chariyāwa*, be about as follows. He shall rise before daylight and wash, then sweep the wihāra and round the Bo tree, fetch the drinking water for the day, filter it, and place it ready for use. Returning to a solitary place he shall then meditate on the regulations. Then he shall offer flowers before the sacred dāgaba or Bo tree, thinking of the great virtues of the Teacher, and of his own faults. Soon after, taking the begging-bowl, he is to follow his superior in his daily round for food, and on their return is to bring water for his feet, and place the alms-bowl before him. After the meal is over, he is to wash the alms-bowl, then again retire, and meditate on kindness and love. About an hour afterwards he is to begin his studies from the books, or copy one of them, asking his superior about passages he does not understand. At sunset he is again to sweep the sacred places, and lighting a lamp, to listen to the teaching of his superior, and repeat such passages from the canon as he has learnt. If he finds he has committed any fault he is to tell his superior; he is to be content with such things as he has, and, keeping under his senses, to grow in wisdom without haughtiness of body, speech, or mind.[1] The superiors, relieved by the novices from any manual labour, were expected to devote themselves all the more earnestly to intellectual culture and meditation. There are five principal kinds of meditation, which in Buddhism takes the place of prayer. The first is called Maitrī-bhāvanā, or meditation on Love, in which the monk thinks of all beings, and longs for happiness for each. First, thinking how happy he himself would be if free from all sorrow, anger, and evil desire, he is then to wish for the same happiness for others; and lastly, to long for the welfare of his foes, remembering their good actions only, and that in some former birth his enemy may have been his father or his friend, he must endeavour in all earnestness and truth to desire for him all the good he would seek for himself. The second is Karunā-bhāvanā, or meditation on Pity, in which he thinks of all beings in distress, realizes as far as he can their unhappy state, and thus awakens the sentiment of pity. The third meditation is Muditā-bhāvanā, or meditation on Gladness, the converse of the last. The fourth is Asubha-bhāvanā, or Purity, in which the monk thinks of the vileness of the body, and of the horrors of disease and corruption, how everything corporeal passes away like the foam of the sea, and how by the continued repetition of birth and death mortals become subject to continual sorrow. We hear of the mirage in the desert cheating the unwary traveller's eyes with the promise of water to quench his burning thirst; but this mirage of human life, raising hopes of joy that turns bitter in the drinking, is a more real mockery. The fifth is Upekshā-bhāvanā, or the meditation on Serenity, wherein the monk thinks of all things that men hold good or bad,—power and oppression, love and hate, riches and want, fame and contempt, youth and beauty, decrepitude and disease,—and regards them all with fixed indifference, with utter calmness and serenity of mind.

[1] For Dina chariyāwa, see Hardy, *Eastern Monachism*, 24–28; for the five meditations, *ibid.* pp. 243, *et seq.*

The Duty of the Laity.—Gautama's ideal was that all men should sooner or later join the order, and thus that an end should be put at once to individual existence and to misery and sin; but even those who did not enrol themselves in the Sangha could obey many of the precepts, and by a virtuous life here raise themselves in their next birth to a higher and less material state of existence. Laymen could thus take the "three refuges," and keep five of the "ten precepts," viz., not to take life, to steal, to lie, to commit adultery or fornication, or to drink strong drink.[2] There are also ten commandments applicable to the laity, viz., to avoid taking life, theft, illicit intercourse, lying, slander, swearing, idle talk, covetousness, anger, and wrong belief, *i.e.*, either superstition, doubt, or heresy; the first three are sins of the body, the next four sins of the mouth, the last three sins of the mind. The following short extracts from the Buddhist Scriptures will perhaps give a better idea of the lay position in the Buddhist system than any longer description in modern terms. In answer to a question as to what he considered the *summum bonum*, Gautama is reported to have said—

"1. To serve wise men, and not to serve fools, to give honour to whom honour is due,—this is the greatest blessing. 2. To dwell in a pleasant land, to have done good deeds in a former birth, to have right desires for one's self,—this is the greatest blessing. 3. Much insight and much education, a complete training and pleasant speech, —this is the greatest blessing. 4. To succour father and mother, to cherish wife and child, to follow a peaceful calling,—this is the greatest blessing. 5. To give alms, and live righteously, to help one's relatives, and do blameless deeds,—this is the greatest blessing. 6. To cease and abstain from sin, to eschew strong drink, not to be weary in well doing,—this is the greatest blessing. 7. Reverence and lowliness, contentment and gratitude, the regular hearing of the law,—this is the greatest blessing. 8. To be long-suffering and meek, to associate with members of the Sangha, religious talk at due seasons,—this is the greatest blessing. 9. Temperance and chastity, a conviction of the four great truths, the hope of Nirvāna,—this is the greatest blessing. 10. A mind unshaken by the things of the world, without anguish or passion, and secure,—this is the greatest blessing. 11. They that act like this are invincible on every side, on every side they walk in safety, and theirs is the greatest blessing."[3]

Self-conquest and *universal charity*, these are the foundation thoughts, the web and the woof of Buddhism, the melodies on the variations of which its enticing harmony is built up. Such a religion could never remain buried in the cloister, or remain the privilege of the few. From the first it became an appeal to the many, and addressed itself not to the learned or the rich but to all mankind, to men and women, slaves and bondmen, Brahmins and Sūdras, nobles and peasants alike. The abuses of caste and priestcraft could no longer grow and thrive among men who looked at every question from a rationalistic standpoint, while their hearts were aglow with real and practical philanthropy. In Guatama's view men differed one from another not by the accident of birth, but by their own attainments and character; the same path to the same salvation lay equally open to all; and even in this life the poor and the despised were welcomed to the ranks of the order, where wealth was abandoned, and birth went for nothing in comparison with character or insight. It is true that, like Christianity, it did not in so many words condemn any of the political institutions amid which it arose; there is nothing said, at least in the older books, against slavery or despotism or wealth; and even as regards caste, Gautama did not directly interfere with it outside the limits of his Society. But the new wine soon burst the old bottles;

[2] Hardy, *Manual of Buddhism*, p. 460.

[3] The above is from the Pāli text of the Khuddaka Pāṭha, edited by Childers, in the *Journal of the Royal As. Soc.*, new series, vol. iv. part ii. Translations have been published by Prof. Childers, *loc. cit.*; by Sir Coomāra Swāmy in his *Sutta Nipāta*, p. 72; and by Gogerly, in the *Ceylon Friend* for June 1839.

the principles of the new creed were quite inconsistent with oppression and wrong of every kind; and the government of Asoka, as Buddhist emperor of India, was probably the most enlightened, and certainly the most philanthropic, which the natives of India have had.

Part III.—Later Buddhism.

It is not surprising that teaching so earnest and so high, so deep-reaching and so radical, should have met with eager acceptance among a people intensely religious, to whom the doctrines of the priests held out so little hope in exchange for the privileges it claimed from them on behalf of an oppressive caste. It is only to be regretted that the history of Buddhism in India lies under so thick a cloud that very little is known of it with certainty. Immediately after the death of Gautama the first council of 500 was held at Rājagriha, as related above, and the young church, in the vigour of its purity and fresh enthusiasm, spread very rapidly among the surrounding tribes. In less than 150 years after the death of its founder, the new religion had become the most powerful in Northern and Central India, and was the state religion of Magadha, whose kings claimed the superiority over the whole peninsula. It probably continued to gain in the number of its adherents till two or three centuries later, but soon after the commencement of our era it began to decay; though Fa Hian, a Chinese pilgrim, who visited India about 400 A.D., found it still flourishing over a large area, it was certainly not increasing, and scarcely maintaining its ground. Hiouen Thsang, another Chinese pilgrim, has left us an account of his journey made about two centuries later, and he found Buddhism in a much lower condition even than it had fallen to in the time of Fa Hian. In the 8th and 9th centuries a great persecution arose, and the Buddhists were so utterly exterminated that there is now not a Buddhist in all India; although of course the effects of so great a movement could not pass away, and it left its mark for ever on the Hinduism which supplanted it. The full reasons for this revolution are not known: but so much is clear, that long before its expulsion Buddhism had become very corrupt; the order had become wealthy and idle; and the laity, instead of following the precepts of the Teacher, had gone back to the old devil-worship, witchcraft, and astrology, which always underlay their nominal beliefs. From the great body of his followers the ethics and philosophy of Guatama were concealed by the mass of legends and superstitions which had grown up around the story of his life; and though the Buddhists no longer propitiated the favour of the gods by sacrifices of living beings, they rested their hopes more on their liberality to the monks than on the harder duties of self-control and charity,—the latter word having thus become even more limited in its meaning than it has among ourselves. Their worship of the relics of the Buddha came very near to rank idolatry; their reverence for their ancestors came very near to worship, and was a dangerous source of emolument to the monks; while the old Hindu gods were regarded much more highly than was at all consistent with the Buddhist Abhidharma

Buddhism had, however, been introduced into Ceylon, at a time when it was comparatively pure, by Mahendra and Sanghamitrā, the son and daughter of the emperor Asoka. It became at once the state religion, and the only religion of the island, on which Brahminism had never gained much hold. Protected there by its isolated position, and by the patriotic spirit which identified it with the Sinhalese nation, whose hereditary enemies, the Tamils, were first Jains and afterwards Hindus, it has retained almost its pristine purity to modern times. From Ceylon it was introduced into Burma in the 5th century A.D., whence it penetrated into Arakan, Kāmbaya, and Pegu, and finally into Siam in the 7th century of our era. As already mentioned, it became, in a less pure form, the state religion of Kashmir about the time of Christ, and was thence carried to Nepal and to Tibet and China. It would be impossible within the limits of this article to trace its various fortunes in these countries, but the following remarks may not be out of place.

It would be hazardous as yet to attempt to trace chronologically the growth of the Buddhist legends, but in one or other of the Buddhist books are found the following ideas, the growth of which was, under the circumstances, almost inevitable. Gautama himself became regarded as omniscient, and as absolutely sinless; he was supposed to have descended of his own accord from heaven into his mother's womb, and to have had no earthly father; angels were said to have assisted at his birth, immediately after which he walked three paces, and in a voice of thunder proclaimed his own greatness. On his formal presentation to his father, an aged saint is said to have worshipped him and prophesied that he would become a Buddha, who would show the people the way of salvation. When the babe was five months old, he was left under a tree, where he meditated so deeply that he worked himself into a trance; and five wise men who were journeying northwards through the air, being miraculously stopped over the place where he was, came down and worshipped him, the hymn put into their mouths surprising us in the midst of so absurd a legend by its beauty; in five stanzas they announce that the babe shall be the teacher of a law which shall be the water to extinguish all the fires of the sorrows of life, the light to enlighten the world, and the chariot to carry us through this wilderness to the promised land; that he shall deliver men from the bonds and shackles of the world, and be the great physician to heal all their diseases, and do away with the miseries of life and death. The only other legend we have of his youth is one in which he is said to have surpassed all his contemporaries in feats of bodily and mental skill, and even to have taught his teachers,—the later forms of this legend bearing a curious resemblance to some parts of the apocryphal "Gospel of the Infancy." In the accounts of his father's home and of his marriage he is surrounded with all the state and wealth of the eldest son and heir to a powerful monarch, whereas it is apparent from the geographical and other details that his father's power can only at most have extended a few miles from his home. It was a pious task to make his abnegation and condescension greater by the comparison between the splendour of the position he abandoned and the poverty in which he afterwards lived; and in countries distant from Kapilavastu the inconsistencies between these glowing accounts and the very names they contain would pass unnoticed by credulous hearers. With the same object of magnifying the person of Buddha, he is related in the legends to have performed at various times a very large number of miracles, mostly mere manifestations of power of no direct advantage to any one, and only designed to impress those who beheld or might hear of them with a belief in his great superiority over other teachers. Of

enough to notice here that it is called by them the Great Vehicle, in contradistinction to that of the southern church, which they call, not without some contempt, the Little Vehicle; and the Great Vehicle, while holding fast to the real foundation of Buddhism, its ethical views of self-conquest and charity, has in fact developed an entirely new religion. This is based on the worship of Maitreya, the Dhyāni-buddhas, Manjūṣri, and Avalōkitēswara, personifications respectively of charity, meditation, serenity, and wisdom. The first of these appears in ancient Buddhism as the name of the Buddha to come, and the last is the holy spirit of the northern Buddhist church. Among the Dhyāni-buddhas, who are philosophical abstractions corresponding to the earthly Buddhas, Amitābha, *i.e.*, Infinite Light, is the heavenly counterpart of Gautama, and soon took the most important place. Avalōkitēswara "proceeded" from him, and manifests him to the world since the death of Buddha; and his worship in the 10th century of our era bore its full fruit in the invention of a being, Ādibuddha, the origin of all things, who, using the wisdom within him, produced by meditation the five Dhyāni-buddhas, of whom Amitābha is the fourth,—a notion curiously similar to the theosophy of the Gnostics, and utterly opposed to the Agnostic materialism of Buddha.

In Tibet especially, the development in doctrine was followed by a development in ecclesiastical government, which runs so remarkably parallel with the development of the Romish hierarchy as to awaken an interest which could scarcely otherwise be found in the senseless and fatal corruptions which have overwhelmed the ancient Buddhist beliefs. The Buddhism introduced into that country in the 7th and 8th centuries of our era was a form of the Great Vehicle, already much corrupted by Siva-ism, a mixture of witchcraft and Hindu philosophy; but it worked a great change among the savage races who then inhabited those remote valleys. In the 13th century the country was possessed by independent chiefs, who struggled with the abbots of the great monasteries for power over the people; and the crozier proved itself in the long run more powerful than the sword. We then find the two leading priests or archbishops, the Pantshen Lāma and the Dalai Lāma, claiming to be official incarnations of Amitābha and Avalōkitēswara; and the latter as such succeeded in obtaining superior political and secular power, leaving to his brother pope his high ecclesiastical position and the aroma of holiness—a division of power which has again resulted in a Guelph and Ghibelin-like rivalry. Lāmaism, with its shaven priests, its bells and rosaries, its images and holy water, its popes and bishops, its abbots and monks of many grades, its processions and feast-days, its confessional and purgatory, and its worship of the double Virgin, so strongly resembles Romanism, that the first Catholic missionaries thought it must be an imitation by the devil of the religion of Christ; and that the resemblance is not in externals only is shown by the present state of Tibet—the oppression of all thought, the idleness and corruption of the monks, the despotism of the Government, and the poverty and beggary of the people.

Of the sacred books of the Northern Buddhists, we have in the original debased Sanskrit only the "Lalita Vistara" a legendary life of Buddha, published in the *Bibliotheca Indica* at Calcutta, the translations of which are mentioned in the beginning of this article. Of the canon of the Southern Buddhists, which is about twice the length of our Bible, we have in the original Pāli only—1. the Dhammapada, a collection of didactic poems edited by Mr Fausböll of Copenhagen, with a Latin translation in 1855; 2. The Khuddaka Pātha, a small collection of hymns published by Professor Childers, with English translation, *Journal of the Royal Asiatic Society* for 1869; and 3. The Upasampāda-kammavācā, the ritual by which laymen are admitted to the order, published by Mr Dickson in the *Journal of the Royal Asiatic Society* for 1873. The Pātimokkha, a manual of the rules of the order in Pāli, has been published by Mr Minayeff with a Russian translation, in 1867. A fuller account by the writer of this article of all the work already accomplished in the editing of Pāli texts, dictionaries, and grammars, will be found in the *Report of the Philological Society for* 1875. Of European works on Buddhism the following are the most important, and references will be found in them to the many smaller treatises on the subject:—Eugène Burnouf, *Introduction à l'histoire du Bouddhisme Indien*, 1844, and *Le Lotus de la Bonne Loi*, 1852; The Rev. Spence Hardy's *Eastern Monachism*, 1850, *Manual of Buddhism*, 1860, and *Legends and Theories of the Buddhists*, 1866, all compiled from Sinhalese sources; Bishop Bigandet's *Legend of the Burmese Buddha*, 1858, 2d edition 1866; St Julien's *Histoire de la vie de Hiouen Thsang*, 1853, and *Mémoires sur les contrées occidentales*, 1856; Professor Lassen's *Indische Alterthumskunde*, vol. ii. 1849, 2d edition 1875; Wassilief *Der Buddhismus, seine Dogmen und Literatur*, 1860, of which a French translation appeared in Paris in 1865; Köppen's *Religion des Buddha*, vol. i. on *Southern Buddhism*, 1857, vol. ii. on *Lāmaism*, 1859; The Rev. Samuel Beal's *Travels of Fa Hian and Sung Yun*, 1869, *Catena of Buddhist Scriptures from the Chinese*, 1871, and *Romantic History of Sākya Buddha from the Chinese-Sanskrit*, 1875; Captain Rogers's *Buddhaghosha's Parables* (from the Burmese), with introduction by Professor Max Müller, 1870; Schlagintweit's *Buddhism in Tibet*, 1863; A. Schiefner, *Eine Tibetische Lebensbeschreibung Schakjamunis*, 1849; Hodgson, *Essays*, 1874. A very large number of other writings on Buddhism have also been published either separately or in different learned journals in Europe and India. Those who wish to refer to those papers will find a list, very complete up to date, of all works, large or small, on the subject in Otto and Ristner's *Buddha and his Doctrines*, a bibliographical essay published in 1869 by Messrs Trübner and Co. of London (T. W. R. D.)

BUDGELL, Eustace (1685-1736), a literary man of some eminence in his time, the son of Dr Gilbert Budgell, was born at St Thomas, near Exeter. He was educated at Christ Church, Oxford, from which he removed to the Inner Temple, London; but instead of studying law, he devoted his whole attention to literature. He was befriended by Addison, who was first cousin to his mother, and who, on being appointed secretary to Lord Wharton, lord-lieutenant of Ireland in 1710, took Budgell with him as one of the clerks of his office. Budgell, who had read the classics and the best English, French, and Italian authors, took part with Steele and Addison in writing the *Tatler*. He was also a contributor to the *Spectator* and the *Guardian*,—his papers being marked with an X in the former, and with an asterisk in the latter. He was subsequently made under-secretary to Addison, chief secretary to the lords justices of Ireland, and deputy-clerk of the council, and was afterwards chosen a member of the Irish parliament. In 1717, when Addison became principal secretary of state in England, he procured for Budgell the place of accountant and comptroller-general of the revenue in Ireland. But the next year, the duke of Bolton being appointed lord-lieutenant, Budgell wrote a lampoon against Mr Webster, his secretary, in which the duke himself was not spared. This led to his removed from his post of accountant-general, upon which he returned to England, and, contrary to the advice of Addison, published his case in a pamphlet. In the year 1720 he lost £20,000 by the South Sea scheme, and afterwards spent £5000 more in unsuccessful attempts to get into parliament. This completed his ruin. He at length employed himself in writing pamphlets against the ministry, and published many papers in the *Craftsman*. In 1733 he began a weekly periodical called the *Bee*, which he continued for above a hundred numbers. By the will of Dr Matthew Tindal, who died in 1733, a legacy of 2000 guineas was left to Budgell; but the bequest (which had, it was alleged, been inserted in the will by Budgell himself) was successfully disputed by

Tindal's nephew and nearest heir, the continuator of Rapin's *History of England*. Hence the satirist—

> "Let Budgell charge low Grub Street on my quill,
> And write whate'er he please—except my will."

It was thought that he had some hand in publishing Dr Tindal's *Christianity as Old as the Creation;* for he often talked of an additional volume on the subject, but never published it. After the cessation of the *Bee*, he became so involved in lawsuits that he was reduced to very distressing straits. He then studied law, and was called to the bar, attending the courts for some time; but being unable to make any progress, and finding his prospects utterly ruined, he determined to put an end to his life. Accordingly, in 1736, he took a boat at Somerset-stairs, after filling his pockets with stones, ordered the waterman to shoot the bridge, and while the boat was passing under it threw himself into the river. On his desk was found a slip of paper with the words—"What Cato did, and Addison approved, cannot be wrong."

Besides the works mentioned above, he wrote a translation of the *Characters* of Theophrastus He never married, but left one natural daughter, who afterwards assumed his name, and became an actress at Drury Lane.

BUDGET (lit. a bag or small sack), the name applied to an account of the ways and means by which a minister of finance purposes to defray the expenditure of the state. In the United Kingdom the chancellor of the exchequer, usually in April, lays before the House of Commons a statement of the actual results of revenue and expenditure in the past finance year ending March 31, showing how far his estimates have been realized, and what surplus or deficit there has been in the income as compared with the expenditure. This is accompanied by another statement in which the chancellor gives an estimate of what the produce of the revenue may be in the year just entered upon, supposing the taxes and duties to remain as they were in the past year, and also an estimate of what the expenditure will be in the current year. If the estimated revenue, after allowing for normal increase of the principal sources of income, be less than the estimated expenditure, this is deemed a case for the imposition of some new, or the increase of some existing, tax or taxes. On the other hand, if the estimated revenue shows a large surplus over the estimated expenditure, there is room for remitting or reducing some tax or taxes, and the extent of this relief is generally limited to the amount of surplus realized in the previous year. The chancellor of the exchequer has to take parliament into confidence on his estimates, both as regards revenue and expenditure; and when the taxation and expenditure obtain the assent of parliament, the results as thus adjusted become the final budget estimate for the year. This system of annual review and adjustment of the public finances obtains not only in the British colonies, but is carried out, with remarkable despatch for so great an empire, in British India. The Indian budget, giving the results of income and expenditure in the year ending December 31, and the prospective estimates, is laid before the Imperial Parliament in the course of the ensuing session. The budget, though modified by different forms, has also long been practised in France, the United States, and other constitutional countries, and of late years has in some cases been adopted by arbitrary powers. Russia began the publication of annual budgets in 1866; Egypt has followed the example: and Turkey, if financially reinstated, will have to submit to a more strict account of her income and expenditure. Apart from national budgets, to be discriminated (1) as budgets passing under parliamentary scrutiny and debate from year to year, and (2) budgets emitted on executive authority, there are in all the greater countries local and municipal taxations and expenditures of only less account than the national. The ordinary budget of the city of Paris has increased from £1,600,000 in the reign of Louis Philippe to £8,000,000 at the present time; while the extraordinary budget, relating chiefly to public improvements and the city debt, is over £4,000,000 more. In federal governments, such as the United States, the German Empire, or the Argentine Republic, the budgets of the several states of the federation have to be consulted, as well as the federal budget, for a knowledge of the finances. The local taxation of the United Kingdom is equal to nearly one half the imperial revenue, and requires in its various provinces the same process of examination. The budget is an essential part of the machinery of representative Governments; and in the rapid progress of state loans, it has begun to be acknowledged by despotic Governments as a necessary basis of confidence between them and their creditors.

BUDWEIS (in Bohemian, *Ceske Budegorice*) the capital of a circle in the Austrian kingdom of Bohemia, is situated on the right bank of the Moldau, at its junction with the Maltsch, in 48° 59′ N. lat. and 14° 30′ E. long. It is well built and partially fortified. Chief among its public buildings are the council house—a handsome structure, and the cathedral, with a great detached tower, built in 1500; it has also an episcopal palace, two gymnasiums, a theological seminary, a training college, a deaf and dumb institution, a theatre, a hospital, and a poorhouse; and a short distance to the north stands the castle of Frauenburg, belonging to Prince Schwarzenberg. Its manufactures are very various, and comprise pottery, nails, wire, parquetry, musical instruments, black-lead pencils, sugar, beer, vinegar, and liqueurs. There are silver and gold mines in the mountains to the east of the town, which are still worked with considerable profit. The railway from Budweis to Linz, laid in 1827 for horse-cars, was the first line constructed in Germany. Budweis was founded by Ottocar II. in 1256, and was received into the number of privileged cities by Frederick II. In 1611 the town was captured by the people of Passau, but was retaken by the imperial general Bouquoi. In 1742, it was besieged by the Bavarians. Population in 1869, 17,413.

BUENOS AYRES, the largest and most important province of the Argentine Republic, is bounded on the N. by the Parana, which separates it from the province of Entre Rios, and by the provinces of Santa Fé, Cordova, and San Luis; on the E. by the Atlantic; on the S. by Patagonia; and on the S. and W. by the country of the Indians, which extends westwards to the Andes. The area of the province is estimated at about 440,000 square miles. Its seaboard along the Rio de la Plata and the ocean is upwards of 900 miles in length. According to the last census of 1869 the population was 488,706, of which 171,404 belong to the city of Buenos Ayres; in the present year (1876) it may be estimated at 600,000, of which 220,000 belong to the city, and 380,000 to the province. By the last returns the number of immigrants is from 60,000 to 90,000 per annum, the greater part of whom remain in the province of Buenos Ayres.

extremity of the province), possesses great natural advantages, which are by no means adequately appreciated. It might be turned to good account as a starting-point for vessels engaged in trade with the South American states that border upon the Pacific, but the difficult and sometimes dangerous navigation of the adjoining seas counterbalances in the meantime the other advantages which it offers. The interior of the country, except where it is intersected by the low mountain ranges of the Ventana and Vaulcan in its southern portions, and the spurs of the Andes in the west, is one vast plain, of which by far the larger part is laid out in *estancias*, or cattle farms, though the soil is in itself well adapted for producing all the European cerealia. Agricultural pursuits, however, are by no means in favour with the natives, who cannot bring themselves to engage in any pursuit that cannot be prosecuted on horseback. "Every man, woman, and child in the country rides," says Parish. "One might fancy one's self in the land of centaurs, amidst a population half-men, half-horses. Even beggars ride on horseback." Some of the cattle-farms are of immense extent; one in particular is mentioned by travellers as comprising more than 300 square miles of land, and yielding an enormous revenue to the proprietor. Some of the largest of them belong to British settlers, and are worked by British servants. The cattle were formerly hunted down and killed merely for the sake of their hides and tongues, while the carcases were abandoned to beasts and birds of prey. They are now slaughtered in abattoirs, where every part of the animal is made available. The beef is salted for exportation; the tallow is boiled down, and now forms an important item in the farmer's revenue; and the trade in hides is steadily increasing. Beef and an infusion of the native tea are the staple food of the natives. In the province of Buenos Ayres there are 45,500,000 sheep, which give a yield of 136,500,000 ℔ unwashed wool; 5,116,000 cows; and 1,500,000 horses. This gives the unusual average of 200 sheep, 20 cows, and 6 horses to every inhabitant. The sheep-farms cover over 40,000,000 acres; and the number of shepherds may be estimated at 30,000, of whom at least a quarter are Irish or Scotch. The total value of exports from Buenos Ayres in 1872 was £9,148,638,—the most important being wool 203,610,000 ℔, sheep-skins 72,970,000 ℔, ox and cow-hides 3,121,758, jerked beef 916,220 qq., tallow 1,182,240 qq. The value of imports in 1872 may be stated approximately at £12,000,000, of which Great Britain contributed £3,800,000, France £3,200,000, Spain £800,000, Brazil £700,000, United States £700,000, Italy £600,000, Belgium £600,000, Germany £100,000, other countries £1,200,000.

Of the cereals grown in Buenos Ayres the most important is maize, which is indigenous to the country. Wheat thrives well in the southern parts of the province, but the inhabitants rarely grow more than enough to supply their own necessities. In the event of a surplus it is commonly exported to Brazil. The vine, fig, orange, and olive have been introduced from the Old World, and are found to suit the climate admirably; but the most valuable of European fruits is the peach. A considerable fruit trade is carried on in coasting vessels by merchants for the most part Italian or French.

The geographical position of Buenos Ayres is such as to enable it completely to control the foreign commercial relations of the entire republic of which it forms a part. The exclusive policy which it has always pursued on this point has often involved it in serious quarrels, not only with many of the South American states and the other provinces of the Argentine Republic, but with England and France. Since the expulsion of General Rosas, the navigation of the Parana and Uruguay has been thrown open, and other measures have been taken to place both the province and city of Buenos Ayres on a level with the other provinces of the republic.

The only towns of any importance, besides the capital, are San Nicolas, which is situated on the Parana, about 200 miles N.W. of Buenos Ayres, and contains a population of about 10,000; San Pedro, also on the Parana, about 150 miles from the capital, in the same direction, with a population of 1000; Chascomus, on a lake of the same name, a place of considerable importance; Dolores, 150 miles south of Buenos Ayres; Villa de Mercedes, Chivilcoy, Las Flores, and Belgrano.

Buenos Ayres, the capital of the Argentine Republic and of the province of Buenos Ayres, is situated on the right bank of the estuary of the La Plata, in 34° 39′ S. lat. and 58° 18′ W. long. The river is at this point so wide that it is quite impossible with the naked eye to distinguish the

opposite bank, and at the same time so shallow, that ships drawing 15 or 16 feet of water must anchor seven or eight miles from the city. Small craft generally anchor in what are called the inner roads, abreast of the city. The depth of water is never sufficient to admit of their coming to shore.

The town of Buenos Ayres is situated in a vast plain extending westwards to the Andes. The level uniformity of its outline is only broken by the spires of the various churches. The stranger, on landing, is struck with the

regularity of the streets, which are quite straight, and intersect each other at distances of 150 yards, forming squares like those of a chess-board, with the cleanly appearance of the houses, and the general air of independence that distinguishes the inhabitants. The houses till lately had never more than two stories, and commonly only one, the rooms of which open into each other, and were chiefly supplied with furniture of a very inferior description from the United States. A chimney was a thing unknown, and the old Spanish brazero alone was employed in heating the damp and white-washed rooms. A great change has, however, taken place in these respects within the last few years. A rage for building has prevailed, and now splendid edifices of three and four stories may be seen in every street. The furniture is now supplied from Europe, the walls are papered, grates and chimneys have come into fashion, and English coal is burned. These comforts are all the more valuable, as the climate of Buenos Ayres is one of the most humid and changeable in the world. The streets of the city are now tolerably paved with granite. They exceed eighty in number, thirty-one of them running from the river side due west, and fifty-one from north to south. The city is being provided with drainage and water supply, and is well lighted with gas. There are eleven parishes, containing sixteen Roman Catholic churches. There are two city hospitals, supported by the municipality, and four for foreigners, belonging to the English, French, Italian, and Irish communities. The theatres are five in number, and there is also a concert-hall. Five markets for the daily supply of the city with provisions are placed at convenient distances; and the *plazas* "11 de Setiembre" and "Constitucion," are the great wool markets for the north and south districts of the camp. Floriculture is a favourite pursuit; and many English and Scotch gardeners have nurseries in the neighbourhood of the town.

Of the public buildings may be noticed the Government house, which is situated on the beach, a residence for the president of the Republic; the cathedral, which is surmounted by a handsome dome, and has a large portico with twelve Corinthian pillars; the cabildo or town-house, in which justice is administered; the churches of La Merced, San Francisco, and San Domingo; and the custom-house. The Plaza de la Victoria, round which some of these edifices are grouped, is the handsomest square in Buenos Ayres. In the centre of it is a handsome monument, erected as a memorial of the War of Independence. When the number of British residents in the town began rapidly to increase application was made to General Rosas for a site for a church. This was immediately granted, and the minister for the time being set an example of liberality and toleration to his countrymen by laying the foundation-stone of the edifice, which cost in all about £4000, half of which was defrayed by the British Government. The Scottish residents have built a small Presbyterian chapel, and the Roman Catholic portion of the English subjects are allowed the use of one of the national churches, in which a priest performs the service. In 1842 the Methodists erected a meeting-house, which is used by all denominations of the British Dissenters. The Protestant Germans, who are pretty numerous, have a church in connection with the Established Church of Prussia. To each of these places of worship schools are attached for children of both sexes. The facilities for education are very considerable, and of these the inhabitants avail themselves extensively. Besides the denominational schools already alluded to, there is a university, attended by about 500 students, and possessing a valuable library. The sons of the wealthier families of the city are very frequently sent to Europe to complete their education at some of the great schools and colleges in France and England. The Buenos Ayreans inherit from their ancestors much of that passion for music which characterizes the Spaniard. Poetry also is much cultivated among them. Besides its university, Buenos Ayres contains many literary and scientific institutions. Of these the most important are the school of medicine, the academy of jurisprudence, a special academy of mathematics and the physical sciences, a normal school, and a society for the promotion of agriculture. The charitable societies, though not very numerous, are rather important. Spanish is the language spoken by the Buenos Ayrean descendants of the old Spanish settlers.

the defence of the country in the event of war, &c. While these internal dissentions were going on, war was declared between the young confederation and the empire of Brazil, and Buenos Ayres was blockaded for a year and a half by a Brazilian fleet. In 1828, however, the siege was raised by the intervention of the English, and by the decisive battle that took place at Ituzaingo favourable to the Argentine arms. This foreign war thus ended, the civil war broke out once more, and was only temporarily checked by the accession of General Rosas to power in 1835. Aiming at territorial aggrandizement, Rosas soon became involved in war with the neighbouring states of Paraguay and Uruguay. England, France, and Brazil interfered, with the intention of effecting an amicable arrangement between the belligerents. Rosas rejected their mediation; and the united fleets of England and France took possession of the Buenos Ayrean fleet which was engaged in the siege of Monte Video, and opened the navigation of the Parana to the merchantmen of all nations. In the subsequent operations Rosas sustained severe losses, yet obstinately refused to yield. In 1848 the English fleet returned home, and was followed by the French in the following year. Brazil was now left to carry on the war alone, but she found ready allies in some of the provinces of the Argentine Confederation, which had long regarded with hatred and aversion the supremacy arrogated by Buenos Ayres. With the assistance of these and the adjoining states of Uruguay and Paraguay, a large army was raised, which, under the command of General Urquiza, defeated Rosas at the battle of Monte Caseros, February 3, 1852. Rosas after his downfall fled to England. Urquiza was appointed provisional director of the confederation; but the Buenos Ayreans protested against his policy, which threatened to undermine the prerogatives they had been long struggling to secure. Civil war again broke out; and in 1853 Buenos Ayres was besieged by the forces of the other states of the confederation. On the 20th of June the siege was raised, and a temporary accommodation effected.

Since the establishment of the Argentine Republic in 1861 the city and province of Buenos Ayres have both very considerably developed their resources. In the province there are now 450 miles of railway, and 2228 miles of telegraph lines; in the city there are six lines of tramway, which traverse the town in every direction. Most of the railways and three of the tramway lines belong to English companies. There are thirteen different lines of steamers trading between Europe and the Port of Buenos Ayres. Population (1876) estimated at about 220,000.

BUFFALO, the English name of *Bubalus*, a genus of Ruminant Mammals, belonging to the family *Bovidæ*, and including the well-known Indian and South African species. The Indian Buffalo (*Bubalus buffalus*) is characterized by its arched forehead, large horns compressed at the base, slightly triangular, and curved in the form of a half moon, and its thick hide covered sparingly with coarse hairs, which become still more scanty in aged individuals. It is a native of India and of the islands forming the Indo-Malay Archipelago, where it now occurs in a state of domestication, and forms a valuable beast of burden; but although it has for ages been under the control of man, the *Bainsha* or tame buffalo shows little or no variation from the wild form. The *Arna* or Wild Buffalo is found in great herds throughout India and the adjacent islands, frequenting swampy grounds in the neighbourhood of woods, eating the long, coarse grass which abounds in such localities, and loving above all things to roll itself in mire, or to plunge up to the ears in any pool or stream it may come upon. This fondness for moisture is equally marked in the tame variety, and is decidedly inconvenient when the animal, laden with goods, yields to its instinct and lies down in any stream that may cross its path. The rutting season occurs in autumn, when several females follow a single male, forming for the time a small herd. The period of gestation lasts for ten months, and the female produces one or two calves at a birth. The *Arna* is a powerful and courageous animal, capable it is said of overthrowing an elephant, and generally more than a match even for the male tiger, which usually declines the combat when not impelled to it by hunger. The Indian driver of a herd of tame buffaloes does not shrink from entering a tiger-frequented jungle, his cattle, with their massive horns, making short work of any tiger that may come in their way. Buffalo fights and fights between buffaloes and tigers form principal features in the public entertainments of Indian princes. In Ceylon the buffalo is put to more useful purposes, where, according to Tennent, the natives make an ingenious use of it when shooting waterfowl in the salt marshes. "Being an object to which the birds are accustomed, the Singhalese train the buffaloes to the sport, and concealed behind the animal, browsing listlessly along, they guide it by ropes attached to its horns, and thus creep undiscovered within shot of the flock." These are known as "sporting buffaloes." The domestic buffalo has spread from its original home in India over the greater part of Southern Asia and of North Africa, and was introduced towards the close of the 6th century into Greece and Italy, forming an invaluable beast of burden in the marshy districts of those countries, where the great breadth of its feet, somewhat resembling in this respect those of the reindeer, give it a decided advantage over the horse and ox. It grazes in herds in the Pontine marshes, where, according to Scaliger, it will lie for hours submerged almost to the muzzle. The milk of the buffalo is plentiful and of excellent quality, the Hindoos making it into a kind of butter called *ghee*; its flesh, however, is not held in much estimation.

The Cape Buffalo (*Bubalus caffer*) is nearly equal in size and fully equal in strength and courage to its Indian congener, from which it is readily distinguished by the form of its horns, these being immensely broad at the base, where they approximate so closely as almost to meet, thus forming, especially in old bulls, a solid rugose mass impenetrable to bullet, and extending from the eye to the back of the head, then spreading horizontally and curving upwards and inwards to the tips, which are usually 4 feet apart. The hide, which is thick and tough, is thinly clad with hair, old animals being entirely naked with the exception of a slight fringe along the back and withers. This buffalo roams in herds over the plains of Central and Southern Africa, always in the near vicinity of water. Formerly herds sometimes numbered five or six hundred, but such has been the havoc wrought among them in recent years by hunters that rarely are they to be seen in companies of more than ten, while in the colonized portion of South Africa they are rapidly dying out. Nor is man their only enemy, for by night when he ceases to disturb they are liable to the attack of the lion, and by this means the wounded, of which there are great numbers, and the diseased are cut off. The Hon. W. H. Drummond, in his work on *The Large Game of South Africa* (1875), gives it as his opinion that in "a few years a buffalo will be as scarce as an elephant now is." This species has never been domesticated, probably owing more to the uncivilized condition of the native inhabitants than to any special intractability in the buffalo itself. Like its Indian ally it is fond of the water, which it visits at regular intervals during the twenty-four hours; it also plasters itself with mud which, when hardened by the sun, protects it from the bite of the great gadflies which in spite of its thick hide seem to cause it considerable annoyance. It is also relieved of a portion of the parasitic ticks, so common on the hides of thick-skinned animals, by means of the red-beaked rhinoceros birds, a dozen or more of which may be seen partly perched on its horns and partly moving about on its back, and picking up the ticks on which they feed. The hunter is often guided by these birds in his search for the buffalo, but oftener still they give timely warning to their host of the dangerous proximity of the hunter, and have thus earned the title of "the buffalo's guardian birds." The Cape Buffalo is the most formidable of the large game of South Africa. Generally, however, it attacks only when wounded, although "rogues" or "solitaires"—terms applied to old bulls which for some reason or other have been expelled from the herd and which wander about morose and savage— often attack without

provocation. When wounded they immediately charge in the direction from which the fire proceeded, and on his skill in avoiding this charge the life of the hunter depends. In buffalo hunting, as in bison hunting, it is specially important "to kill with a single bullet." The hide of the Cape Buffalo is made by the Kaffres into shields impervious to musket shot.

BUFFALO, an American city, the capital of Erie County, in the State of New York, U.S., about 293 miles N.W. from New York, in 42° 53' N. lat. and 78° 55' W. long. It is a port at the east end of Lake Erie, at the mouth of Buffalo River, and at the head of Niagara River, which is here crossed by a fine iron railroad bridge. The city runs for about five miles along the shore of the lake and Niagara River. In population Buffalo is the third city in New York, and the eleventh in the United States. It was founded in 1801, became a military post in 1813, and was burned by the British on the last day of the year 1813. After the war, the place was rebuilt, and in 1832 it attained the rank of a city. In 1820 it contained 2095 inhabitants. After the opening of the Erie Canal in 1825, its growth was rapid, the population being 8653 in 1830, 18,213 in 1840, 42,261 in 1850, 81,129 in 1860, 117,714 in 1870, and 134,238 in 1875. The city commands a fine view of the lake; the climate is pleasant and healthful; the streets, broad and generally lined with trees, are well paved, lighted, and supplied with sewers. There are many fine residences with attractive grounds, and numerous squares and public places. A combination of parks or pleasure grounds has been laid out, extending to over 500 acres. It comprises three sections, situated respectively in the northern, western, and eastern parts of the city, connected by boulevards which together afford a drive of nearly 10 miles. The most prominent public buildings are the City and County Hall, a granite structure, in the form of a double Roman cross, with a tower 245 feet high, just erected at a cost of over $2,000,000; the United States Custom House and Post Office, the State Arsenal, and the Erie County Penitentiary, which is one of the six penal establishments of New York, intermediate between the reformatories and the state prisons. A state asylum for the insane is in process of construction at North Buffalo, with a front of about 2700 feet and a capacity for 600 patients. It will be one of the largest institutions of the kind in the United States, and will cost not less than $3,000,000. The city contains 76 churches, the most imposing edifices being St Joseph's Cathedral (Roman Catholic) and St Paul's (Episcopal). The public schools comprise a central grammar school and thirty-six district schools. Four orphan-asylum schools are also maintained. One of the eight state normal schools is situated here. Among other educational institutions are Canisius College, founded by the Jesuit fathers; St Joseph's College, conducted by the Christian brothers; Martin Luther College (theological); St Mary's Academy and Industrial School for girls, and the Medical College of the University of Buffalo. The charitable institutions of the city are numerous. There are several libraries, the most important being that of the Young Men's Association, with about 30,000 volumes, and the Grosvenor Free Library, which contains about 15,000 volumes of valuable reference works. The former society has a commodious hall and library building adjoining. The Society of Natural Sciences has made an extensive collection of minerals and fossil casts, and the Buffalo Historical Society has a large library and cabinet. There are published in the city eight daily newspapers, including four in German, one tri-weekly, fourteen weeklies, four monthlies, and three quarterlies. The city is divided into thirteen wards, and is governed by a mayor and twenty-six aldermen. It has a paid fire department, with steam fire-engines and a fire-alarm telegraph, has an efficient police, and is well supplied with water from the Niagara River. The assessed value of property in 1873 was about $38,000,000.

The position of Buffalo on the great water and railway channels of communication between the West and the East gives it a commercial importance surpassed by that of few other American cities. Its harbour is capacious, and is protected by extensive breakwaters. The city is the centre of an important system of railroads. Besides other lines which converge here, it is the eastern terminus of the Lake Shore and Michigan Southern Railway, of the Canada Southern, and of a branch of the Grand Trunk Railway of Canada; it is the western terminus of the Erie Canal, the New York Central Railway, and a division of the Erie Railway. There has been a large decrease in the extent of the lake commerce since 1862, owing to the increase of railroad facilities. The registered marine of the port, June 30, 1874, comprised 801 vessels of 162,789 tons, of which 533 were canal boats. The annual value of the imports from Canada is between $2,000,000 and $3,000,000; the exports are less than $500,000. Since 1870 Buffalo has been a port of foreign entry for imports, which are conveyed thither, in bond, by rail from New York, &c. The number of lake vessels that arrived in 1874 was 3720; the clearance numbered 3727; 7643 canal boats arrived, and about the same number cleared; the latter carried 1,448,172 tons of freight, valued at $46,244,875. The immense quantities of grain moving from the Western States to the seaboard constitute the most important feature of the commerce of the city. The aggregate receipts (including flour) by lake and Grand Trunk and Canada Southern Railways in 1874 were 70,030,555 bushels. The receipts during the ten years ending with 1874 amounted to 522,874,944 bushels. For receiving, storing, and transferring this vast amount of produce to canal boats and railway cars, there are thirty elevators, capable together of storing 6,875,000 bushels, and of transferring no less than 2,672,000 bushels a day. Many of these elevating warehouses are costly structures of stone, or of iron and brick. Several of them have grain "driers" attached. Live-stock and lumber from the Western States and Canada, and coal from Pennsylvania, are also leading items in commerce. In 1874, 504,594 cattle, 783,800 sheep, 1,431,800 hogs, and 21,937 horses, amounting in value to nearly $60,000,000 passed through Buffalo. For the accommodation of this traffic, extensive and well-arranged yards have been erected at the east end of the city. The receipts of lumber by lake in 1874 amounted to 145,624,639 feet, besides about 40,000,000 shingles, and 25,000,000 staves. The imports of coal comprised 800,000 tons. The coal trade is rapidly increasing. The manufacturing interests of Buffalo are extensive, and have grown with marked rapidity in recent years. The leading establishments are blast furnaces, rolling-mills, foundries, breweries, tanneries, manufactories of agricultural implements, and flour-mills. Of the last-named there are eleven, with a yearly capacity of 830,000 barrels, the average annual production of flour being about 250,000 barrels. Wooden ship-building was formerly carried on here, but it has been superseded by iron ship-building. Two extensive establishments are devoted to this industry; these have constructed the finest lake steamers, besides supplying the Government with a number of iron revenue vessels. The number of ships built at Buffalo in 1874 was thirty-one, but they were mostly small ones. Many canal boats are

Poland May 25, 1661, of French parents, who returned to their native country shortly after their son's birth, and settled at Rouen. He was educated at the Jesuits' college there, and was received into the order at the age of nineteen. Soon after his admission a dispute with the archbishop regarding certain points in theology compelled him to leave Rouen. He went to Rome, but did not long remain there; and on his return to France he retired to the college of the Jesuits at Paris, where he spent the rest of his life, studying and writing, and fulfilling with much success his duties as a college lecturer. He seems indeed to have been an admirable teacher, having, as his works show, a great power of lucid and precise exposition. Buffier's object in his *Traité des vérités premières*, his best known philosophical work, is to discover the ultimate principles upon which all knowledge is based, to lay down "propositions so clear and obvious that they can neither be proved nor refuted by other propositions of greater perspicuity." The basis of all human knowledge and the foundation of every other truth he finds in the sense we have of our own existence and of what we feel within ourselves. He thus takes as the foundation of his philosophy substantially the same ground as Descartes, *cogito ergo sum;* but the superstructure is reared on very different principles. Descartes tried to reach a knowledge of the not-self by an *a priori* or metaphysical proof of the divine existence. Buffier rejects this sort of evidence as useless. I want, he in effect says, to obtain a certain knowledge of what is distinct from myself, and this I can never do by mere metaphysical demonstration, which only gives me the hypothetical certainty of ideas logically connected together; in order to know what exists distinct from myself I must have recourse to "common sense." Common sense he defines to be "that disposition which nature has placed in all or most men, in order to enable them, when they have arrived at the age and use of reason, to form a common and uniform judgment with respect to objects different from the internal sentiment of their own perception, which judgment is not the consequence of any anterior principle." The truths which this "disposition of nature" obliges us to accept can neither be proved nor disproved; they are admitted in all countries and at all times; and they are practically followed by all men, even by those who reject them speculatively. But Buffier does not claim for the truths of common sense the same absolute certainty as characterizes either the knowledge we have of our own existence or the logical deductions we make from our thoughts; they possess merely the highest probability, and the man who rejects them is, as he pointedly puts it, to be considered a fool, but he is not in so doing guilty of a contradiction. The greater part of the *Traité* is devoted to an enumeration and examination of those truths. They are such as the following:—"There are other beings and other men in the world besides myself;" "All men have not combined to deceive me." But axioms like "2 + 2 = 4," or "the whole is greater than a part" are mere logical connections of ideas, not truths of common sense. Buffier's aversion to scholastic refinements and unmeaning definitions has not unfrequently given to his writings an appearance of shallowness and want of metaphysical insight; but his merit as one of the earliest to recognize the psychological as distinguished from the metaphysical side of Descartes's principle, and to use it, with no inconsiderable skill, as the basis of an analysis of the human mind, similar to that enjoined by Locke, will always be acknowledged. In this he has anticipated the spirit and method as well as many of the results of Reid and the Scotch school. The *Traité* appeared in 1717, and was followed in 1724 by the *Eléments de Métaphysique*. Buffier also wrote a "French Grammar on a new plan," and a number of historical essays. Most of his works appeared in a collected form in 1732, and an English translation of the *Traité* was published in 1780.

BUFFON, GEORGE LOUIS LECLERC, COMTE DE, was born on 7th September 1707, at Montbard, in Burgundy, and died at Paris on the 15th April 1788. His father, M. Leclerc de Buffon, was councillor of the Burgundian parliament, and his mother, Anne Christine Marlin, appears to have possessed considerable natural gifts. Buffon was the eldest of five children, and does not seem to have been in any way a precocious child. On the contrary, he seems from his earliest years to have been characterized more especially by great perseverance, patience, knowledge of the value of time, and exceptional powers of steady application and protracted labour. He was originally destined to his father's profession, and studied law at the college of Jesuits at Dijon; but he soon exhibited a marked predilection for the study of the physical sciences, and more particularly for mathematics. Whilst at Dijon he made the acquaintance of Lord Kingston, a young Englishman, who was at the time staying there along with his tutor, a man of ability and discernment. In this agreeable companionship, Buffon travelled through Italy, being then nineteen years of age. Returning to France, he commenced to study at Angers, still in company with Lord Kingston; but having quarrelled with a young Englishman at play, and subsequently wounded him, he was compelled to leave this town. He thereupon removed to Paris, and during his sojourn in the capital he translated Newton's *Fluxions* and Hales's *Vegetable Statics*, which he subsequently presented to the Academy of Sciences. From Paris he proceeded to England, where he remained three months; but his travels seem to have ended here. At twenty-five years of age he succeeded to a considerable property, inherited from his mother, and from this time onward his life was a completely independent one, and he was enabled to devote himself entirely to his scientific pursuits. He returned now to France, and lived partly at Montbard and partly at Paris.

Though loving pleasure, and not keeping himself free from the prevalent vices of the age in which he lived, Buffon spent the remainder of his life in regular scientific labour, employing an amanuensis, and thus securing a permanent record of his work. At first he directed his attention more especially to mathematics, physics, and agriculture, and his chief original papers are connected with these subjects. In the spring of 1739 he was elected a member of the Academy of Sciences; and at a later period of the same year he was appointed keeper of the *Jardin du Roi* and of the Royal Museum. This appears to have finally determined him to devote himself to the biological sciences in particular, and he commenced to collect materials for his *Natural History*. In the preparation of this voluminous work, he associated with himself Daubenton, to whom the descriptive and anatomical portions of the treatise were entrusted, and the first three volumes made their appearance in the year 1749. In the year 1752 (not in 1743 or 1760, as sometimes stated), he married Marie Françoise de Saint-Belin. He seems to have been fondly attached to her, and felt deeply her death, which took place at Montbard in 1769. The remainder of Buffon's life, as a private individual, presents nothing of special interest. He belonged to a very long-lived race, his father having attained the age of ninety-three, and his grandfather eighty-seven years. He died himself at the age of eighty-one, of vesical calculus, having refused to allow of any operation for his relief. He left one son, George Louis-Marie Leclerc, who was an officer in the French army, and who died by the guillotine, at the age of thirty, on the 10th July 1793 (22 Messidor, An II.), having espoused the party of the duke of Orleans.

Buffon was a member of the French Academy, perpetual treasurer of the Academy of Sciences, Fellow of the Royal Society of London, and member of the Academies of Berlin, St Petersburg, Dijon, and of most of the learned societies then existing in Europe. Of handsome person and noble presence, endowed with many of the external gifts of nature, and rejoicing in the social advantages of high rank and large possessions, he is mainly known by his published scientific writings. Without being a profound original investigator, in the modern sense of this term, Buffon possessed considerable power of generalization, along with the art of expressing his ideas in a clear and generally attractive form. His chief defects as a scientific writer are, that he was given to excessive and hasty generalization, so that his hypotheses, however seemingly brilliant, are often destitute of any sufficient basis in observed facts, whilst his literary style is not unfrequently theatrical and turgid, and a great want of method and order is commonly observable in his writings.

His great work is the *Histoire Naturelle, générale et particulière;* and it can undoubtedly claim the merit of having been the first work to present the previously isolated and apparently disconnected facts of natural history in a popular and generally intelligible form. The sensation which was made by its appearance in successive parts was very great, and it certainly effected much good in its time by generally diffusing a taste for the study of nature. For a work so vast, however—aiming, as it did, at being little less than a general encyclopædia of the sciences,—Buffon's capacities may, without disparagement, be said to have been insufficient, as is shown by the great weakness of parts of the work (such as that relating to mineralogy). The *Histoire Naturelle* passed through several editions, and was translated into various languages. The edition most highly prized by collectors, on account of the beauty of its plates, is the first, which was published in Paris (1749-1804) in forty-four quarto volumes, the publication extending over more than fifty years. In the preparation of the first fifteen volumes of this edition (1749-67) Buffon was assisted by Daubenton, and subsequently by Guéneau de Montbéliard, the Abbé Bexon, and Sonnini de Manoncourt. The following seven volumes form a supplement to the preceding, and appeared in 1774-89. These were succeeded by nine volumes on the Birds (1770-83), and these were followed by five volumes on Minerals (1783-88). The remaining eight volumes, which complete this edition, appeared after Buffon's death, and comprise Reptiles, Fishes, and Cetaceans. They were executed by Lacépède, and were published in successive volumes between 1788 and 1804. A second edition was commenced in 1774 and completed in 1804, in thirty-six volumes quarto. It is in most respects similar to the first edition, except that the anatomical descriptions are suppressed, and the supplement recast. Of the remaining editions of Buffon, the best is that which was commenced under the editorship of Lamouroux, and completed under that of Desmarets, in forty volumes octavo (1824-32). It is the only modern edition in which the anatomical descriptions of Daubenton are preserved. Though not without his enemies—scientific and clerical—Buffon had many warm friends, and his death was marked by the delivery of highly laudatory addresses, by Condorcet at the Academy of Sciences, Vicq-d'Azir at the Académie Française and Bressonet before the Society of Agriculture. Extravagantly belauded by some, and vehemently attacked by others, we can recognize his merits without blinding ourselves to his defects.

This brief notice of his life may be fitly closed by the following quotation from Cuvier, in which the great French naturalist, whilst rejecting some speculations which recent science has generally accepted as probable, ascribes to Buffon the honour of being the first to clearly apprehend what is now admitted as the true principle of guidance in investigating the order of the universe:—"It is impossible to defend, in all their details, either the first or the second of Buffon's theories of the earth. This comet which strikes off portions of the sun, these vitrified and incandescent planets which refrigerate by degrees, some more rapidly than others, those organized beings which appear successively on the surface of the planets, as their temperature becomes sufficiently lowered, can only be regarded as flights of fancy. But Buffon has not less the merit of having been the first to point out clearly that the actual condition of the globe is the result of a succession of changes, of which we can find the evidences to-day; and it is he who first drew the observation of all investigators to the phenomena by which these changes can be unravelled." (H. A. N.)

BUG, a name common to all the species belonging to the *Cimicidæ*, a family of Hemipterous Insects, the best known example of which is the House Bug or Bed Bug (*Cimex lectularius*). This disgusting insect is of an oval shape, of a rusty red colour, and, in common with the whole tribe to which it belongs, gives off an offensive odour when touched; unlike the others, however, it is wingless. The bug is provided with a proboscis, which when at rest lies along the inferior side of the thorax, and through which it sucks the blood of man, the sole food of this species. It is nocturnal in its habits, remaining concealed by day in crevices of bed furniture, among the hangings, or behind the wall paper, and shows considerable activity in its nightly raids in search of food. The female deposits her eggs at the beginning of summer in crevices of wood and other retired situations, and in three weeks they emerge as small, white, and almost transparent larvæ. These change their skin very frequently before undergoing metamorphosis, which in their case is "incomplete," the pupa closely resembling the perfect insect, and attaining its full development in eleven weeks. Two centuries ago it was a rare insect in Britain, and probably owes its name, which is derived from a Celtic word signifying "ghost" or "goblin," to the terror which its attacks at first inspired. Other species of bugs suck the blood of

BUGULMA, a town of European Russia, in the government of Samara, 243 miles from the city of that name, on the small river Bugulminka, a sub-tributary of the Volga, in 54° 32′ N. lat. and 52° 47′ E. long. The town rose into existence about 1741–5, and was peopled by soldiers, exiles, and peasants. During the Pugacheff insurrection it was vainly besieged by the rebels. In 1781 it was made a town of the Ufa government; in 1806 it was transferred to Orenburg, and in 1851 to Samara. Its principal importance is derived from its situation at the junction of two great roads from Ufa and Orenburg, by which it maintains an extensive transit trade. A great annual fair is held from 14th to 21st of September (o. s.). Population in 1867, 5455.

BUGURUSLAN, a town of European Russia in the government of Samara, situated at the junction of the rivers Kinell and Tarkhanka, 177 miles E.N.E. of Samara, in 53° 39′ N. lat. and 52° 25′ E. long. It dates from about 1748, and in the time of the Pugacheff revolt was the scene of the outrages of Karpoff's band. Its changes from government to government coincide with those of Bugulma. The principal buildings are two or three churches, a monastery, a hospital, and a caravanserai. It manufactures leather, wax, potash, and beer, and carries on a pretty extensive trade. There are two annual fairs. Population in 1867, 7450.

BUHLE, JOHANN GOTTLIEB (1763–1821), distinguished as a scholar and an historian of philosophy, was born at Brunswick, and graduated at the university of Göttingen, where he obtained a chair at a very early age. Thence he was called to the professorship of ancient languages at Moscow. After his return to Brunswick he was appointed to the chair of natural law, which he held till his death in 1821. Buhle's activity was great, and the productions of his pen are numerous. He edited *Aratus* and part of *Aristotle* (the Bipontine edition, 5 vols.), the first volume of which is a masterly survey of Aristotelian literature. His fame, however, is principally derived from his labours on the history of philosophy. The *Geschichte der philos. Vernunft*, 1793, was suspended after the first volume, but the *Handbuch der Geschichte der Philosophie*, 8 vols. 1796–1804, is a very complete and valuable work. More important than either of these is the *Geschichte der neuern Philosophie*, forming one of the great series of histories of the sciences from the Renaissance. It is a work of much learning, and is well written; its faults are general weakness in critical appreciation and want of due sense of proportion. The *History of Modern Philosophy* has been translated into French, 6 vols. 1806.

BUHL-WORK, otherwise Bool, Boule, or Boulle-work, is a kind of inlaying and ornamentation of cabinet-work, so named after the inventor André Charles Boule, a celebrated French cabinetmaker (1642–1732) By a happy selection of different woods from India and Brazil, arranged with great taste, and the use of brass, ivory, gold, tortoise-shell, &c., Boule produced upon his furniture arabesques and pictures, representing a variety of animals, flowers, and fruits; and he finally succeeded in producing historical scenes, as battles and hunts, landscapes, and other artistic effects. Louis XIV. appreciated his abilities, gave him lodgings in the Louvre, and, in 1672, appointed him engraver in ordinary of the royal seals. In the patent authorizing this he received also the designations of "architect, painter, carver in mosaic, artist in cabinet-work, chaser, inlayer, and designer of figures." His skill was great in all these branches, and he carried them to a high degree of artistic perfection in timepieces, screens, furniture, and other articles. He worked for the royal residences and for foreign princes, and attained fortune and position.

The beginnings of art in carving are found amongst the relics of prehistoric races, and when it arrived at the degree of perfection it afterwards attained in the East, inlaying was a natural result. We find this to have been practised by the ancient Egyptain and other Asiatic races. Its attendant, veneering, was also employed by them, workmen applying the veneer with glue being represented on the Egyptian monuments. As civilization advanced westward, the Greeks and Romans followed in the art, the latter race inlaying their furniture with marquetry or tarsia-work, using ivory, ebony, box, palm, bird's-eye maple, beech, and other woods. Their bronze articles they damascened with ornaments of the precious metals and metallic amalgams. The spirit of the Middle Ages was adverse to the development of this art, and but few traces of it are found. In the South Kensington Museum is a coffer of cypress, with flat surface imagery filled in with coloured wax composition, that dates from the 14th century. The Venetians derived their marquetry from Persia and India, as is indicated by the geometric patterns inlaid with ivory, metal, and woods, stained of various colours. Florence took a prominent place in this manufacture in the 15th century. Certosina-work was the result; it was so called from the great Certosa, Charterhouse, or Carthusian monastery, between Milan and Pavia, in the choir-fittings of which this kind of ornament, ivory inlaid into solid cypress and walnut wood, is employed. Work in the Persian style, with its geometric figures, still reaches us from Bombay, the present great seat of the Parsees.

The Renaissance artists chiefly employed wood in making furniture, ornamenting it with gilding and painting, and inlaying it with agate, carnelian, lapis-lazuli, marble of various tints, ivory, tortoise-shell, mother-of-pearl, and various woods. Boule improved upon this by inlaying brass devices into wood or tortoise-shell, which last he greatly used according to the design he had immediately in view, whether flowers, scenes, scrolls, &c.; to these he sometimes added enamelled metal. In this process the brass is thin, and, like the ornamental wood or tortoise-shell, forms a veneer. In the first instance the production of his work was costly, owing to the quantity of valuable material that was cut away and wasted, and, in addition, the labour lost in separately cutting for each article or copy of a pattern. By a subsequent improvement Boule effected an economy by gluing together various sheets of material and sawing through the whole, so that an equal number of figures and matrices were produced at one operation. Boule adopted from time to time various plans for the improvement of his designs. He placed gold-leaf or other suitable material under the tortoise-shell to produce such effect as he required; he chased the brass-work with a graver for a like purpose, and, when the metal required to be fastened down with brass pins or nails, these were hammered flat and disguised by ornamental chasing. He also adopted, in relief or in the round, brass feet, brackets, edgings, and other ornaments of appropriate design, partly to protect the corners and edges of his work, and partly for decoration. He subsequently used other brass mountings, such as claw-feet to altars and pedestals, or figures in high or low relief, according to the effect he desired to produce. Boule's contemporary, Reisner, a German, used a variety of woods, tulip-wood more especially, in the production of flowers and other ornamental designs, contrasting the dark with the light kinds, crossing the grain, and employing other ingenious devices. After him this particular style was called Reisner-work. The Spaniards of the 16th century used silver for inlaying.

BUILDING

lation of ilding archi- ture.

THE art of building comprises the practice of civil architecture, or the mechanical operations necessary to carry the designs of the architect into effect. It is not unfrequently called *practical architecture;* but the adoption of this term would tend only to confuse, by rendering it difficult to make the distinction generally understood between architecture as a fine or liberal art and architecture as a mechanical art. The execution of works of architecture necessarily includes building, but building is frequently employed when the result is not architectural; a man may be a competent builder without being an architect, but no one can be an accomplished architect unless he be competent to specify and direct all the operations of building. A scientific knowledge of the principles of masonry, carpentry, joinery, &c., and of the qualities, strength, and resistance of materials, though of the utmost importance to an architect, must be attended by a minute acquaintance with a great variety of less ambitious details. Such are those which relate to the arrangement of a plan for the greatest possible degree of convenience on the smallest space, and at the least expense; its transference to the ground; the preparation and formation of foundations; the arrangement and construction of drains, sewers, and vent-shafts; the varieties of walling with stone, and of laying bricks in brickwork; the merit of the various modes of bonding and tying walls, both lengthwise and across; the arrangement of gutters on roofs, to get sufficient fall, and to conduct the water to the least inconvenient places for fixing trunks to lead it down; the arrangement and formation of flues; the protection of walls from damp, of timber from moisture and stagnant air, and of metals generally from exciting causes; the cost of materials and labour, and the quantity of each required to produce certain results. Together with these, an architect ought to be practically acquainted with all the modes of operation in all the trades or arts employed in building, and to be able minutely to estimate beforehand the absolute cost involved in the execution of a proposed structure. The power to do the latter necessarily involves that of measuring work, and ascertaining the quantities done. These things may certainly be referred to the surveyor or measurer, but they are not the less incumbent on the architect, who cannot be said to be thoroughly master of building, or the practice of his profession, unless he be skilled in these operations.

Building includes what is called construction, which is the branch of the science of architecture relating to the practical execution of the works required to produce any structure; it will therefore be necessary to explain the subject in a general manner before entering upon building in detail.

It may, perhaps, be useful to premise that, should it occur to some readers that the present article has too great a tendency to supply information on the manner of building in a modern style, and that the earlier method is not elaborated, it must be remembered that, although the styles of architecture have varied at different periods, buildings, wherever similar materials are employed, must be constructed on much the same principles. Greater scientific knowledge of the natures and properties of materials has, however, given to the modern workman immense advantages over his mediæval brother craftsman, and caused many changes in the details of the trade, or art of building, although stones, bricks, mortar, &c., then as now, formed the element of the more solid parts of all edifices. The introduction of fir, too, in place of the more solid and durable timber oak, has likewise occasioned similar changes, too numerous to mention in detail, in the sister arts of carpentry and joinery, probably also causing the division of the carpenter's trade of the mediæval period. Certain exceptional features of mediæval work did exist, and most, if not all, will, it is hoped, be found referred to in this article.

General Principles of Construction.

Stabil the ol of con struct Wall.

The object of construction is to adapt and combine fit materials in such a manner that they shall retain in use the forms and dispositions assigned to them. If an upright wall be properly constructed upon a sufficient foundation, the combined mass will retain its position, and bear pressure acting in the direction of gravity, to any extent that the ground on which it stands and the component materials of the wall can sustain. But pressure acting laterally has a necessary tendency to overturn a wall, and therefore it will be the aim of the constructor to compel, as far as possible, all forces that can act upon an upright wall to act in the direction of gravity, or else to give it permanent means of resistance in the direction opposite to that in which a disturbing force may act. Thus when an arch is built to bear against an upright wall, a buttress or other counterfort is applied in a direction opposed to the pressure of the arch. Arch. In like manner the inclined roof of a building, spanning from wall to wall, tends to thrust out the walls; and hence a tie is applied to hold the opposite sides of the roof together at its base, where alone a tie can be fully efficient, and thus the roof is made to act upon the walls wholly in the direction of gravity; or where an efficient tie is inapplicable, buttresses or counterforts are added to the walls, to enable them to resist the pressure outwards. Roof. A beam laid horizontally from wall to wall, as a girder to carry a floor and its load, may sag or bend downwards, and tend thereby to force out the walls; or the beam itself may break. Beam. Both these contingencies are obviated by trussing, which renders the beam stiff enough to place its load on the walls in the direction of gravity, and strong enough to carry it safely. Or if the beam be rigid in its nature, or uncertain in its structure, or both (as cast-iron is), and will break without bending, the constructor, by the smith's art, will supply a check and ensure it against

in his works if he makes them dependent upon wrought iron. Cast-iron is brittle, and may not be exposed with impunity to transverse strain, especially if such strain be attended by action tending to induce vibration; it expands and contracts under the influence of heat, but it resists compression in every direction, and if used in small bodies, is valuable as a means of connecting other materials. Timber, being practically unchangeable in the direction of its length from the mere absorption of either heat or humidity, and at the same time practically both inextensible and incompressible in that direction, and being also readily wrought and easily combined alike with other timber and with iron, is a valuable material in the hands of the constructor; but it shrinks and swells in the direction of its thickness, and, in consequence, is subject to rapid decay when exposed to alternations of moisture and dryness; and although in many varieties timber is perdurable and unchangeable in form if it be kept either altogether free from moisture or always wholly wet, its quality of inextensibility is greatly diminished in value to the constructor on account of the comparatively slight resistance it offers to compressing power, and the comparative ease with which its fibrous structure is torn asunder. From this cause it cannot be grasped or otherwise held so that its power of resisting extension may be made available in any degree proportioned to its strength; whilst its quality of incompressibility in the opposite direction is of less value to the constructor for many purposes which require that quality in the material, because it absorbs moisture by the ends of the fibre more readily, and with a far more mischievous effect, than it does in the direction in which it is compressible. Hence timber rots more rapidly by the ends than by the sides.

Stone and brick, the other main available materials in general construction, keep their places in combination by means of gravity. They may be merely packed together, but in general they are compacted by means of mortar or cement, so that although the main constituent materials are wholly incompressible, masses of either or of both combined in structures are compressible until the setting medium has indurated to a like condition of hardness. That kind of stone is best fitted for the purposes of general construction which is least absorbent of moisture, and at the same time free to work. Absorbent stone exposed to the weather rapidly disintegrates; and for the most part non-absorbent stone is so hard that it cannot always be used with a due regard to economy. When, therefore, fitting stone of both qualities can be obtained, the harder stone can be exposed to the weather, or to the action which the softer stone cannot resist, and forms the main body of the structure of the latter so protected. The hard and the soft should be made to bear alike, and should therefore be coursed and bonded together by the mason's art, whether the work be of stone wrought into blocks and gauged to thickness, or of rough dressed or otherwise unshaped rubble compacted with mortar.

Good bricks are less absorbent of moisture than any stone of the same degree of hardness, and are better non-conductors of heat than stone. As the basis of a stable structure, brickwork is more to be relied upon than stone in the form of rubble, when the constituents bear the relation to one another last above referred to, the setting material being the same in both; because the brick, by its shaped form, seats itself truly, and produces by bonding a more perfectly combined mass; whilst the imperfectly shaped and variously sized stone as dressed rubble can neither bed nor bond truly,—the inequalities of the form having to be compensated for with mortar, and the irregularity of size of the main constituent accounted for by the introduction of larger and smaller stones. The most perfect stability is to be obtained, nevertheless, from truly wrought and accurately seated and bonded blocks of stone, mortar being used to no greater extent than may be necessary to exclude wind or water, to prevent the disintegrating action of both upon even the most durable stone. When water alone is to be dealt with, and especially when it is liable to act with force, mortar is necessary for securing to every block in the structure its own full weight and the aid of every other collateral and super-imposed stone in order to resist the loosening effect which water in powerful action is sure to produce.

Particular objects of construction. In the application of construction to any particular object, the nature of the object will greatly affect the character of the constructions and the materials of which they are to be formed.

Each complete in itself. Every piece of construction should be complete in itself, and independent as such of everything beyond it. A door or a gate serves its purpose by an application wholly foreign to itself; but it is a good and effective or a bad and ineffective piece of construction, independently of the posts to which it may be hung. Whilst the wheel of a wheelbarrow, comprising fellies, spokes, and axle-tree, is a piece of construction complete in itself, and independent as such of everything beyond it, an arch of masonry, however large it may be, is not necessarily a piece of construction complete in itself,—it would fall to pieces without abutments. *Bridge.* Thus, a bridge consisting of a series of arches, however extensive, may be but one piece of construction, no arch being complete in itself without the collateral arches in the series to serve as its abutments, and the whole series being dependent thereby upon the ultimate abutments of the bridge, without which the structure would not stand. This illustration is not intended to apply to the widely distended masses of the older bridges, by which each pier becomes sufficient to abut the arches springing from it, but which tend, in providing for a way over a river, to choke up the way by the river itself, or compel the river to throw it down, or otherwise destroy its own banks. A bridge, of which the way is formed upon arches of masonry, may be thus but one piece of construction; and in like manner, *Pointed church or cathedral.* that paragon of constructive skill, the complete church, whether cathedral or otherwise, as built in the Pointed style when that style was practised in full accordance with true constructive principles, is but one piece of construction. As in the long series of arches in a bridge, viaduct, or other such work, in which the piers are vertical supports to the bridging structure, and may be of no greater substance than is necessary to bear the weight coming directly by vertical pressure from the superincumbent structure and its possible load, but throwing all the pressure arising from weight acting laterally, or as thrust, upon terminal abutments,—nothing may be omitted, as nothing can be removed from the structure of the Pointed arch cathedral, or other church built in that style, the whole system of which is bridge-like in construction, without leaving something unsupported or unresisted that requires vertical support or lateral resistance. The western towers of a Pointed cathedral form effective abutments to the long series of arches of the inner ranges over the piers which stand between the nave and the aisles on both sides, whilst turrets or massive buttresses and deep porches upon the northern and southern transept fronts perform the same services in respect of the arches of the transepts. The counteracting east end of the chancel forms a true constructive abutment to the arches of the chancel, whilst the tower, with, it may be, a spire upon it, at the intersection of the four grand compartments of the cross, gives, by its weight, abuttal to them all. The want of this last-named grand and essential body in the system is but too strongly marked in many of the English cathedrals, by the iron bars which have been applied to tie in the arches of the nave;

transepts, and chancel, and to relieve the piers upon which the transept arches bear at a higher level from the thrust to which, being without the weight of a tower upon them, they have continually yielded. Transversely the weight and the thrust of the vaulted ceilings of the nave are brought up to, and thrown against, the piers of the clerestory, which stand upon the main piers or columns of the interior below, and are abutted by flying buttresses, which carry the thrust down to the pinnacle-weighted buttresses of the outer aisle walls, which have already received the weight and thrust of the vaulted ceilings of the aisles themselves. Corbels in the walls and spreading capitals upon shafts take the weight directly, and leave the walls and piers but little encumbered in the middle, so that the vertical structure is continued upwards without bearing upon the springing stones of the arches.

But it is not necessary that the arch employed should be the Pointed arch, to produce combinations as effective in construction as the most perfectly designed and extensively elaborated work of the kind referred to as models of constructive skill; the skill consists in a full and clear perception of the bearing and leaning of every part, and of the means necessary to support and counteract the bearings and the leanings within the reasonable limits of the work with reference to its object and purpose—to the end that the work may become complete in itself, and independent as a piece of construction of everything beyond it.

ills.

In making reference to the noble works of construction above referred to, in which the art of the mason is mainly employed, as works exhibiting construction most fully and most truly, the hall must not be passed over without remark, and of all the great halls of the class to which Westminster Hall belongs, it is itself the most effective as a work of construction; and its effect is wholly produced by the magnificent roof which covers it. This roof is a piece of carpentry admirably designed to resolve it into a compact body to act upon the walls in the direction of gravity alone. But the designer may not have felt quite certain of the results, so whilst erecting massive walls on which to place his elaborate combination of timber, he threw up against the lateral walls a series of flying buttresses to check any tendency of the roof to spread under its own weight in the absence of a thorough transverse tie; for these buttresses are said to be independent of the walls, not being built into them.

est-
nster
ill.

An application of the principles of construction exhibited in the most perfect works of constructive skill ever executed, as above indicated, may be made in the rougher operations of mere practical utility. The sides of cuttings through certain earths in the formation of lines of inland communication, whether carriage roads, railways, or canals, are sometimes required to be widened out to an inordinate extent because of the looseness or slipperiness of the soil, or must otherwise be retained or held upright by special constructions. The expense of the first formation of a cutting under given circumstances is easily calculable, and so is the time within which the work may be effected. Experience has proved that there is for every soil a limit in depth beyond which it becomes more expedient to drift the required way, and construct a vaulted tunnel of sufficient dimensions, than to make an open cutting with the requisite slopes. Even when the first cost would not decide the question, the preference is nevertheless often given to the tunnel because of the greater security of constructed work.

attings.

Retaining
valls.

Before proceeding to the consideration of the means of enabling opposite retaining walls to assist each other, it may be worth while to consider, whether retaining walls are generally constructed so as best to adapt their components to the duty to be performed. No one would place a buttress intended to resist the thrust of an arch within

Buttress.

the springing walls, or under the arch whose thrust is to be resisted; yet in the construction of retaining walls, according to the common practice, the counterfort is placed on that side which receives the pressure, where its utility is very questionable, except to keep the retaining wall from falling back against its load, which, from the transverse section generally given to such walls, they would be apt to do, if not so propped up by their counterforts. Wharf and quay walls, and the revetment walls of military works, may require a face unbroken by projections; but this is not the case with retaining walls for roads and railways, where a long line of projecting buttresses would be unobjectionable, the counterforts becoming buttresses and merely changing places with the wall. On account of the common practice of battering the faces of retaining walls in curved lines, and of radiating the beds of the brickwork composing them from the centre of curvature in every part, the back of the wall must contain more setting material than the face, with the same quantity of solid brick, that is, if the work be bonded through. Counterforts must be built in the same courses, and consequently must have still thicker beds of compressible mortar than the wall; or the bond between the wall and its counterfort must be dropped, and the counterfort thus become utterly inefficient.

Batt-

The retaining walls in the cutting upon the line of the extension of the London and North-Western Railway, from Camden Town to Euston Square, are, according to the common practice, built wholly of brickwork in radiating courses and with counterforts following their own contour. In this case the centre of gravity of the wall falls wholly

Exam-
at Ca-
Town.

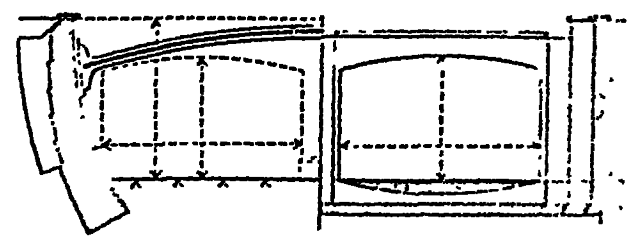

Fig. 1.

Transverse section of the Euston Incline retaining walls, one-half as executed with cast-iron struts to counterforted and relieving walls, and the other half with the brick-built abutting beam to counter-arched retaining walls strutted at the toes of the springing walls by inverted arches

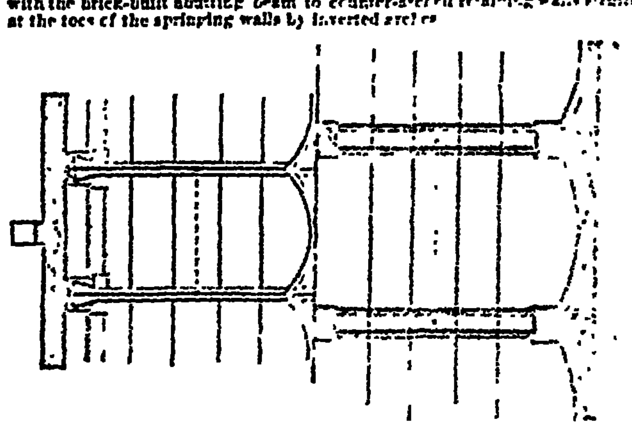

fig. 1, to make each aid the other, was applied to meet the emergency; but this is limited to the upper parts of the walls.

Abutting struts from opposite walls, occurring at intervals only, leave the intermediate portions of the walls exposed to pressure from behind without support, unless these intermediate portions are so disposed as to communicate the pressure upon them to the struts. Hence a common retaining wall, abutted at intervals, would require these intervals to be more or less distant, in proportion to the strength of the wall between them. Instead, therefore, of a continuous wall on each side of the cutting, buttress walls should be placed at intervals, opposite to one another, and strutted apart at their toes by an inverted arch (as in fig. 2); and above, at a height sufficient for whatever traffic the cutting is to accommodate, by a built beam of brickwork, in vertical courses, supported on an arch, and prevented from rising under the pressure by an invert upon it, as in fig. 3. This built beam will then be, as it were, a piece of walling turned down on its vertical transverse section, and will resist any pressure brought upon it through the buttress walls, to the full extent of the power of such a wall built vertically to bear weight laid upon its summit; the pressure would be applied in the line of the greatest power of resistance, and there would be no tendency to yield, except to a crushing force. Let such transverse buttress walls, so strutted apart, with the road between them, be the springing walls of longitudinal counter-arched retaining walls, which, being built vertically and in horizontal courses, but arched in plan, against the ground to be retained, will carry all the force exerted against them to their springing walls, and the springing walls or buttresses will communicate, through the struts, the power of resistance of each side to the other, and thus insure the security of both.

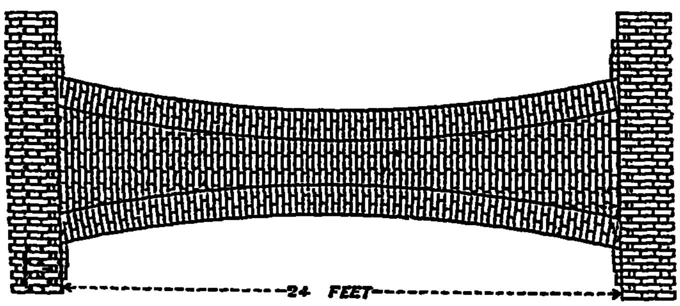

FIG. 3.—Built abutting Beams.

This arrangement may be carried to any extent in height, by repeating the abutting beam or strut at such intervals as the thrust to be resisted and the strength of the buttress springing-walls may require.

ty of als. To constructions thus arranged, any requisite power may be given, by altering the quantity of materials in each part,—the length of the buttresses transversely of the cutting, the number of struts to each pair of buttresses, or the length of the compartments. The thickness of the buttresses should be in proportion to their height and length, and their length should be in proportion to the flatness and weight of the struts with their arches, and to the space in height between any two of them, as well as to the magnitude of the thrust brought to them by the counter-arched retaining walls. The inverted arch below and the built beam above must, of course, have sufficient substance to enable them to resist, without yielding in any direction, the pressure brought to them through the buttresses; and the retaining walls themselves must have substance given to them according to their height, to the pressure they are liable to receive from behind, to the length of the compartments, and to the extent of their flexure;—subject, of course, as to all these, to the nature of the materials, workmanship, and mode of structure.

The positive strength which such constructions should possess depends much, of course, upon the nature of the soil, and its susceptibility of being affected by external influences; but it depends, even in a greater degree, upon the manner in which the constructions can be applied to the ground they are intended to retain. A very slight power will retain at rest a body which the exertion of great force could not stop if once in motion, and a half-brick counter-arch, set in close contact with undisturbed ground, would hold safely up what three times the substance would not stop if there were space and opportunity for motion between the ground and the brickwork. It is impossible, therefore, to state precisely what is the least strength which the retaining constructions must have, but there can be no question that too much strength is better than too little, and it is generally cheaper to pay in materials than in labour to save materials. Strength of the constructions.

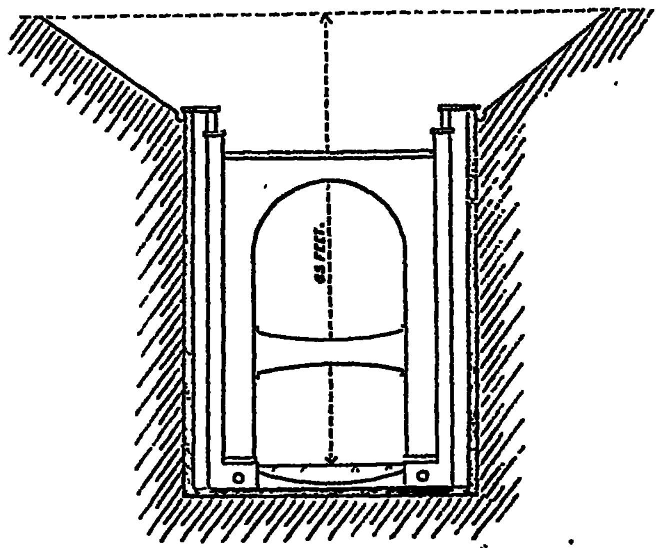

FIG. 4.—Transverse section through the centre of a Bay.

The diagrams, figs. 4 and 5, represent a cutting 65 feet deep to the level of the rails. It is assumed that the ground at the top may stand for the first 15 feet at less than 2 to 1, and that it may, therefore, be cheaper to run out to that depth with slopes, leaving 50 feet from the rails, or about 52 feet in all, to be retained. As the bricklayer may follow up the excavator with bay after bay, his work lying mostly on the side and out of the way of the excavator, the latter would run out the spoil without interruption, his work being benched onwards and shored as he proceeded. As every compartment, with its buttresses, invert, abutting beams, and counter-arches is complete in itself, the ground being backed against the counter-arches as the work rises, the shoring would come out, and be sent on for use on the forward benches. The invert may be turned upon footings in half-brick rings, to get the largest quantity of solid resisting matter in the curved line. At a height from the surface of the rails sufficient for headway—assumed at 14 feet 6 inches—a 14-inch bonded arch is turned from buttress to buttress, springing from skewbacks on corbelled courses. Upon the back of this arch the abutting beam is built of brick on end and edge, bonded as a wall, with beds vertical and widening over the haunches of the discharging arch and under the similar inverted arch turned upon it; so that although the beam be in the centre but 21 inches deep, it presents an abutment at each end of three times that depth. The object of the invert over the abutting beam is to stiffen it, and to bring down and distribute the weight and pressure from the buttresses more effectually. The built beam, and its sustaining and stiffening arches, An example of a cutting.

should be composed of particularly well-formed bricks of really good quality, set in cement or in some quick-setting mortar, that there may be no yielding to the pressure which must be immediately thrown upon this part of the construction. Another built beam, of greater depth, because of the absence of any inverted arch to stiffen it, is thrown across over the back of a semicircular arch, with its abutting ends extended in like manner.

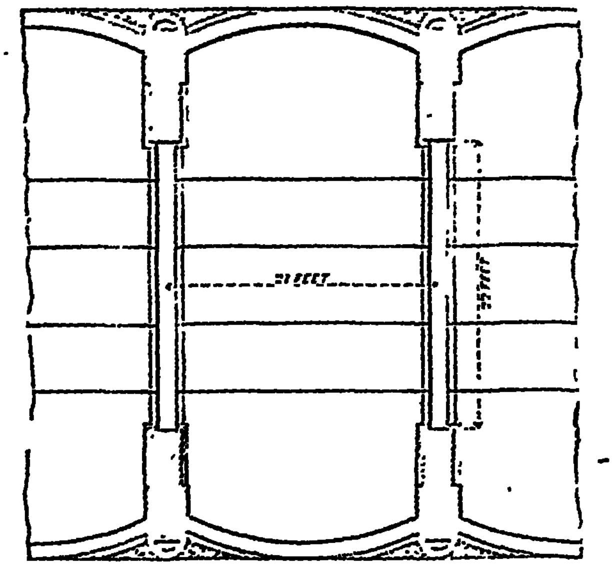

FIG. 5.—Plan at twice the scale of the Section (fig. 4).

Drains. To relieve the work from water, a drain being run along over the middle of the inverts, or side-drains being passed by ring culverts through the buttresses, drain-shafts are carried up at the backs of the buttresses against the springings of the counter-arches, to within a few feet of the surface. These shafts, being steened with open joints at intervals to admit drainage water and communicating with the drains below, prevent the possibility of water lodging about the backs of the counter-arches, or even in the ground itself. The drain shafts should be semi-domed with bricks set dry and covered in, and the walls also backed up with good clean gravel, through which the surface water may percolate and pass freely down to the shafts.

The constructions are assumed to be of brickwork, for the obvious reason that the cases supposed being clay cuttings, brick is the material which would be most economical. But if masonry be cheaper, it may of course be used with the same effect. Where a cutting intersects loose beds of laminated stone, and particularly strata inclined to the horizon, so as to be unsafe with the ordinary slopes, such constructions are available; and in cases where the sides of the cutting will stand vertically or nearly so, as in chalk, it may be useful to apply similar constructions, though of slighter character, to check the separation and fall of masses from the precipitous sides. It is obvious, too, that these constructions present the means of security, when the stratum forming the base of any cutting is too weak to bear the weights of slopes, or of retained sides, without rising between them. Sheet-piling may be driven to any depth along the backs of the counter-arched walls so as to be retained at the head by the walls: and thus in effect the walls would be carried down to a safe depth, even through the weak stratum; whereas such piling at the toes of slopes is commonly found to be almost if not wholly useless, for the want of a stay to the head.

Construction of civic structures generally. The ignitibility of timber, and the rapidity with which it burns when placed in circumstances so favourable to that effect as by its disposition in an erected building, have led to its prohibition for the purposes of the main enclosures of houses and buildings generally, in London, and in many of the larger provincial towns. It is possible, however, so to protect timber employed in the enclosures and for the internal partitions and floors of buildings as to render mere dwelling-houses practically incombustible. Whilst, however, the liability of timber to take fire and to burn may in a great measure be counteracted, and notwithstanding that this material combines the advantage of economy with security, stone and brick are undoubtedly better adapted for the main structure of a building. Brick or stone, or brick and stone together, with a setting material, ought to be employed, but in such manner only as to be free from dependence upon other and less trustworthy materials. The most perfect erections as buildings are those in the composition of which this principle has been understood and fairly practised. If adventitious aid be given to brick or stone walls by foreign materials, the materials ought to be at the least harmless. Iron in bulk is not a proper Iron substance to incorporate with walls because of its great expansibility by heat; but iron used in thin laminæ, as hoop-iron laid in walls in the bed-joints of the brick or Hoo stone, cannot be productive of any bad consequences, while it is most beneficial in that form as a tie to the structure.

Bricks come ready shaped to the hands of the workman Brick in a form the best adapted for the arrangement in the con- struc struction of a wall which, under the designation of bond, gives it such a degree of consistency that a weight placed upon the top is carried by the wall in every part throughout its whole thickness, and throughout a greater or less proportion of the length according to the height of the wall. Stone, on the other hand, comes to the workman without regular form; and with skill on his part to dispose and arrange the materials, good erections may be produced of rubble; for although the thickness of which walls may be built of rubble with safety will depend in a great degree upon the quality of the mortar, much depends also on the skill of the workman in bedding and bonding the stones. Under any circumstances, however, a wall so composed cannot safely be charged with heavy weights, or be exposed to the vibrating action of floors, until the mortar shall have indurated to some extent; whereas a wall of brickwork is secure by the horizontal bedding of the bricks, and by the effect of the transverse bond which the alternation of header and stretcher almost necessarily produces

the height of the structure; but they ought not to be determined by that condition alone. Chimney-breasts, or other buttress-like projections, built up with a wall, and extending to more than the thickness of the wall, make it in fact stronger in its transverse section, and justify less general thickness in the body of the wall, whilst window and other openings in a wall leave piers which ought to be of greater thickness than the mere height would require. But all returns, indeed, whether as chimney-breasts or as cross walls, built and bonded with a wall, tend to render unnecessary the full thickness which the height might require; whilst, as just intimated, the omission of portions of a wall for door and window openings should be compensated for by additional substance to the parts which remain. Walls subjected to undue action, such as that arising from slight joists tailed into them, or that occasioned by inclined timbers, as under galleries in churches, chapels, and theatres, require to be of greater thickness than they otherwise would; whilst it is quite wonderful to what great heights brick walls may be built with safety, if they are well built, and exposed to no other action than direct vertical weight. When, indeed, such walls stand upon a sufficient foundation, direct vertical weight without motion is a means of security to the walls so long as the weight is reasonably within the power of resistance of the materials to crushing pressure. The object to be looked at, therefore—the walls being honestly built—is, as before remarked, to make the weight to be imposed upon any wall act upon its solids vertically and steadily.

Floors upon girders, or framed to strong trimmers—the girders or the trimmer-joists running into and bearing upon the piers or solids of the walls—are far preferable to what are termed single floors, of which each joist runs into the wall. Girders as the basis of floors render plates in the walls wholly unnecessary, by depositing the weight in the right places, without requiring plates to carry it on from the weaker to the stronger places; and being of necessity stout and rigid, they form a fair tie and strut to the walls into which their bearing ends are tailed. Whether girders or trimmer-joists be employed for placing the weight of floors upon the walls of a building in the safest manner, the bearing timbers ought to be placed upon pieces of stone as templets built into the walls, and to be made to take a cog-hold of the templets, so as to enable them to tie and stay the walls by means of the cogs. It is by means of the girder bearing upon the solids of the walls, though with bad carpentry, that the French are able to carry up their soft, coursed-rubble, stone walls to heights that would certainly be unsafe if the walls were seamed with wooden plates, and shaken by floors of single joist; such, for instance, as a wall of a total height of say 85 feet, with a thickness of 18 English inches on the ground-floor and through six stories, or about 65 feet, and finished by a gable,—the basement being vaulted with walls about 20 inches thick. It is by means of the solidity given to the floors by the girders, and the solid bearings which the girders obtain, that the floors are able to carry the dead weight of matter which renders them practically fireproof, as described below, in addition to the moving weights to which the floors of buildings are necessarily exposed in use. We can and do frame floors most effectively by carpentry alone; whereas the French do the work so badly, that no important bearing is, or indeed may be, trusted by them to the framed joint—dog-nailed stirrup straps of iron being always brought in aid. But the common practice in England is to use single or unframed floors, which carry the weight and the vibration to which floors are exposed into the walls, over voids as well as over solids; while the French frame their floors to or upon girders, by means of which the floors are brought to bear upon the solids of the walls. The walls are thus not only less exposed to vibratory action, but are both tied together and strutted apart with better effect by the stout girders stiffened by joists than by joists which themselves require some foreign aid to stiffen them. Moreover, single floors of joists, unless trimmed at frequent intervals, when, indeed, they may be termed half-framed, are supposed to require plates of timber laid along the inside faces of outer walls and upon internal walls. This defect is avoided by French builders, who exclude all timber, except the bearing ends of girders, from their walls, and use framed floors.

Wall-plate and roof. When the walls of a building have reached their full height, the wall-plate comes into use legitimately—to cope the walls, in fact, and to form a curb as a base upon which to place the roof, which should deposit its weight, nevertheless, by means of its tie-beams upon the plates over the solids of the wall below, and which should, moreover, oversail, so as to cover and effectually shelter from the weather the enclosing walls also.

Cast-iron girders. In setting forth the structural advantages derivable from the use of girders as the bases of floors, it may be necessary to repeat the warning already intimated against the use of girders of a material of uncertain strength, and of treacherous character when exposed to transverse strain. Cast-iron is of uncertain strength, mainly because of the imperfections which the most skilful founders, with the best materials and every appliance at command, cannot always avoid, and which are most liable to occur in the production of complex forms in long lengths; whilst careless founding and rapid cooling are contingencies connected with the production of cast-iron girders—which are necessarily long and complex castings. Cast-iron is treacherous, inasmuch as it is brittle and liable to be startled into fracture by impact trifling when compared with what it may have borne safely as a dead-weight. Proving long metal castings by straining them upon their transverse section does but aggravate imperfections, and leave the casting weaker; whilst no dead-weight proof is proof against blows or other action inducing vibration. It is only under circumstances which do not admit of concussive action upon the beam, or which prevent it from vibrating under any shock that may reach it, that cast-iron can be safely used in beams of long lengths to carry heavy weights, without some appliance to mitigate, at least, the imperfections which this substance exhibits. The application of wrought iron tension bars as soles to beams and girders of cast-iron **Tension bars.** would prevent the most serious consequences from attending the failure of the casting, if the beam were also prevented by binders, or by other sufficient means, from turning round when the blow produces an oblique fracture. Wrought iron girders can be and are now extensively used to carry floors, partitions, and even walls with safety.

Foundations. Inasmuch as some soils are liable to change in form, expanding and contracting under meteorological influences, as clays which swell when wetted and shrink when dried, concrete foundations are commonly interposed upon such soils to protect the building from derangement from this cause; or rather, for that purpose walls of the cheaper material, concrete, instead of the more expensive brick or stone structure, are brought up from a level sufficiently below the ordinary surface of the ground. When concrete is used to obviate the tendency of the soil to yield to pressure, expanse or extent of base is required; and the concrete, being widely spread, should therefore be deep or thick as a layer, only with reference to its own power of transmitting to the ground the weight of the wall to be built upon it, without breaking across or being crushed. But when concrete is used as a substitute for a wall, in carrying a wall down to a low level, it is in fact a wall, wide only in proportion to its comparative weakness in the

absence of manipulated bond in its construction, and encased by the soil within which it is placed.

The foundation of a building of ordinary weight is, for the most part, sufficiently provided for by applying what are technically termed footings to the walls. The reason for a footing is, that the wall obtains thereby a bearing upon a breadth of ground so much greater than its own width or thickness above the footing, as to compensate for the difference between the power of resisting pressure of the wall and of the ground or ultimate foundation upon which the wall is to rest. It will be clear from this, that if a building is to be erected upon rock as hard as the main constituent of the walls, no expanded footings will be necessary; if upon chalk, upon strong or upon weak gravel, upon sand, or upon clay, the footing must be expanded with reference to the power of resistance of the stratum to be used as a foundation; whilst in or upon made ground, or other loose and badly combined or imperfectly resisting soil, a solid platform bearing evenly over the ground, and wide enough not to sink into it, becomes necessary under the constructed footing. For this purpose the easiest, the most familiar, and, for most purposes, the most effectual and durable, is a layer of concrete, which may be formed so as to cover a surface large enough to obtain from the most yielding soil the amount of resistance to pressure required to support the weight of the intended building. It will be evident that upon a concrete foundation a footing or expanded base may or may not be required to a wall, according to the hardness of the concrete and the kind of wall to be built; but it is perhaps better to give the footing to the wall than to wait for the sufficient induration of the concrete to enable the wall to do without a footing; and better still, to lay the concrete of such height only with reference to the spread or extent of base beyond the toes of the footing, as the gravel of which the concrete is made would stand at in an uncombined condition. Concrete, indeed, is at all times more safely to be regarded as a substance to be placed as a layer, than as a substance to be set up as a wall; for although excellent erections as walls may be made of concrete—as erections in the same form may be made of tempered clay or of pisé-work—neither concrete nor tempered clay is to be regarded as a proper substance with which to form the lofty walls of buildings in towns. The use of lime concrete involves walls of a considerable thickness; Portland cement concrete, a stronger material and having the property of hardening rapidly, is more commonly used for thin walls. Several patents have been taken for erecting buildings with concrete walls by the construction of troughs formed of frames and movable boards or shutters. But considerable doubt exists as to the extent to which such walls can be built, as many have cracked, proved leaky, and shown other faults; whilst much economy does not result except where the work is very plain and straightforward, where little is spent on subsequent finish, and where the materials can be obtained at very little cost either for themselves or for carriage.

Construction for Protection against Fire.—Houses seldom take fire from common accidents, such as occur to the lighter movable furniture and to drapery; but, for the most part, from the exposure of timber in or about the structure to the continued action of fire, or of heat capable sooner or later of inducing the combustion of timber; and as the source is most commonly in defective gas-piping, or in some stove, furnace, flue, pipe, or tube, for generating or for conveying heat, or for removing the products of combustion, much of the real danger to buildings from fire would be prevented by avoiding that degree of proximity of timber to all such things as can lead to its combustion. With a view to lessen the danger to which buildings with timber in their structure are exposed from fire, it will be well to consider how far the timber and wooden fittings commonly used may be necessary either to the stability of the buildings, or to the comfort and convenience of the inhabitants. But it is not our intention to describe here the various modes of fire-proof construction, but only to notice the principles upon which ordinary buildings may be rendered nearly *incombustible*. So long as danger of fire is brought to buildings through pipes and tubes, the necessity must be admitted of guarding the combustible materials used in buildings from any chance of becoming ignited. When heat is produced and passed through pipes in any manufactory, whether it be to act as power, or for drying or for warming, the fires used may be guarded, and the machinery which regulates the intensity of the heat to be transmitted may be under constant care; but even in such cases there can be no certainty that the heat shall not at some time arrive at the point of danger. But when heat is diffused throughout dwelling-houses by means of apparatus which is committed to persons unskilled in its use, and unconscious or careless of the danger which may arise from neglect, it seems impossible to lay down inflexible rules for distances from timber which shall render it safe from heated pipes. Twelve or fifteen inches may not be a greater distance than safety requires under some circumstances, whilst there are many cases in which the actual contact of such pipes with timber is hardly inconsistent with safety. When the air about heated bodies is not confined, as it would be within the timbers of an ordinary floor, a distance between the timber and the heated surface equal to the longest diameter of the tube or pipe will be found sufficient if the temperature of the pipe does not exceed that of boiling water. It is to be understood that a piece of wood will bear a powerful dead-heat upon its sides for an indefinite period without igniting, unless a transverse section of the fibre, as at or around a live knot, or where a branch had been lopped, present itself to the action. It is by the end that a piece of wood exposed to powerful heat most readily ignites. The gases evolved in the substance of the timber by the action of heat applied to its surface, expanding as they are evolved, are thrown out by the pores among the fibres at the ends, if the ends are near enough to the action to allow of this effect, with less power than may be enough to obtain vent for the inflammable gases laterally.

or 40 feet; and walls of such lengths and heights could hardly be deemed safe if not more than one brick thick. Consequently, a greater thickness has been prescribed as the least thickness of the walls of buildings of the sizes indicated. In the older Metropolitan Building Acts much greater thicknesses were prescribed for the walls likely to be the longer walls; whilst the only necessity for more than one brick rises from structural requisites, and not from any insufficiency of a wall of solid brickwork one brick thick as a means of preventing the spread of fire.

rtitions.

But the requisites of the structure would be as well fulfilled by one-brick walls upon the long sides as by 1½ brick walls, if the ordinary internal cross partition for dividing a house into front and back rooms were built of brickwork abutting upon, and at right angles to, the longer walls, and carried up coursed and bonded with them. That is to say, party-walls of one brick or 9 inches in thickness, connected at their ends by 1½-brick or 13-inch front and back walls, and at or about the middle of their length by other 9-inch cross walls, would be at the least as strong as 1½-brick party-walls, though connected in the same manner at the two ends, but without the abutting and connecting cross wall of brickwork. Instead, however, of such internal cross walls, hollow partitions of timber are commonly used in all stories above the basement story; and it is by these partitions, and by the light and highly inflammable wooden stairs, that fire extends itself rapidly throughout ordinary dwelling-houses; whilst the substitution of a brick wall for the cross timber partition would in most cases justify the abatement of a half brick of the thickness otherwise necessary to party-walls, and give an indestructible internal support to the floors, whereby also one of the means by which fire travels rapidly through a house would be removed. It is true that there must be openings as doorways, and fittings in them for doors, in such internal partition wall; but the wall could not carry fire up from floor to floor through its own heart, as the hollow wood-lathed quartering partition carries it. Doors and shutters, and door window linings, in and against brick or stone walls, may take fire and burn in any story of an ordinarily built dwelling-house, without carrying it beyond the story in which the fire occurs; for a plastered ceiling of the most common description will resist the action of flame upon its surface for a long time, and plastering of really good quality, though upon wood laths, will keep fire off from the joists by which it is held up, almost without danger, so long as the fire acts upon the face only of the plastering. If, however, fire reach the joists through the agency of hollow quartering partitions, the enemy has turned the flank of the plastering, and the floors and skirtings above and behind it taking fire, the building almost inevitably falls a prey to the flames. Any step, indeed, from the hollow quartering partition towards a solid wall is a step towards security. A brick wall is, perhaps, the best internal partition for all the purposes of strength and security from fire; and in small houses, which will not afford the expense of 9-inch walls, half-brick walls with 9-inch jambs at the doors, and short 9-inch piers on alternate sides of the partition, at intervals of 3 or 4 feet in length, will give sufficient strength; but even quartering partitions, if based upon brick walls, may be rendered nearly proof against fire by brick-nogging them, especially if care be taken to fill in with brickwork between the joists over the head of one partition and under the sill of another, as well as between the timbers of the partitions. Filling in between the joists, and up as high as the skirtings go, will do something, indeed, towards diminishing the dangerous tendency of even lathed and plastered timber partitions; whilst the adoption of the plan now commonly practised in Paris, in forming not only internal partitions, but the rearward external enclosures of buildings, would secure to the structure the structural efficiency of timber on end in carrying weight, and give the solid and incombustible character of a brick or stone wall to a partition or enclosure which is structurally of timber. The plan referred to is, to frame and brace with timber quarterings much in the manner practised in England, except that the timber used in Paris is commonly oak, and is generally seasoned previously. The framed structure being complete, strong oak batten-laths, from 2 to 3 inches wide, are nailed up to the quarterings horizontally, at 4, 6, or even 8 inches apart, according to the character of the work, throughout the whole height of the enclosure or partition; and the spaces between the quarterings, and behind the laths, are loosely built up with rough stone rubble, which the laths prevent from falling out until the next process has been effected. This is, to apply a strong mortar, which in Paris is mainly composed of plaster of Paris, which is there of excellent quality, laid on from both sides at the same time, and pressed through from the opposite sides so that the mortar meets and incorporates, embedding the stone rubble by filling up every interstice, and with so much body on the surfaces as to cover up and embed also the timber and the laths—in such a manner, indeed, as to render the concretion of stone and plaster, when thoroughly set, an independent body, and giving strength to rather than receiving support from the timber.

Partitions as formed in England

The English brick-nogged partition is, in point of structure, nothing without the aid of timber. The plastering is merely spread upon the surfaces of brick and wood, and is fragile in the extreme, and always liable to crack and drop off. This lathed and plastered partition is composed of the hollow framework of the timber quarters, with two slight thicknesses of mortar, as plastering, hung upon slighter laths, over and between which the flaccid mortar forms a key for itself; but all necessarily depends upon the timber, and fails with it wherever decay or fire may destroy it.

Stairs.

Only second in importance to the internal partition as a source of danger, or as a means of safety, are the stairs; and the stairs are second in importance only when the partitions are made to carry the floors of the several stories. In England, and in London particularly, even when the steps and intermediate landings are of stone, it is but too common to find the passage from the street door to the foot of the stairs, and the floors which connect flight with flight at the several landings, either wholly of wood or of slight stone paving laid upon wooden joists or bearers. Any stone paving upon wooden joists will certainly retard the action of fire upon the joists, especially if assisted by a well-plastered ceiling; but in this, again, if the floors be not formed of wholly incombustible materials, the French practice as to floors would be better than ours.

In Paris stone stairs are far less common in modern houses than they are in London in houses of corresponding character and date; but wooden staircases in Paris are rendered almost as safe as common stone staircases are in England, by a process similar in character to that applied to partitions and enclosures. The result is an almost incombustible structure. Wooden staircases formed between brick or stone walls, or between partitions of the kind above described as commonly made in modern buildings in Paris (that is, filled with a solid mass of concreted rubble), may perhaps be set on fire, but they can hardly burn.

Ceilings and floors.

It has been remarked that a mere plastered ceiling will resist the action of fire for a long time, although the plastering be upon wooden laths, and the laths nailed to joists of timber; and as fire does not readily act downwards, flooring boards may take fire from above without any immediately serious consequence to the joists under them,

so long as there is no access of air from below. But the English indoor plastering upon laths is commonly of the most fragile kind, and the slightest weight falling upon the back of a ceiling will make a breach through it, whilst the floors are commonly of deal laid upon fir joists, and are exposed to the action of fire from below directly the lathed and plastered ceiling has failed; if, indeed, the fire have not found its way to the joists under the flooring boards by the hollow lathed and plastered quartering partitions. In the timber enclosures and partitions, which economy induces the Paris builder to introduce as substitutes for walls, the timber is so embedded in and made part of a solid concrete, as to be protected from almost every casualty of which it is susceptible. But the French render their floors also so nearly incombustible as to leave but little to desire in that respect, and in a manner attainable with single joists, as well, at the least, as with joists framed into girders. According to their practice, the ceiling *must* be formed before the upper surface or floor is laid, as the ceiling is formed from above instead of from below. The carpenters' work being complete, strong batten-laths are nailed up to the under sides of the joists, as laths are in England; but they are much thicker and wider than our laths, and are placed so far apart that not more, perhaps, than one-half of the space is occupied by the laths. The laths being affixed—and they must be soundly nailed, as they have a heavy weight to carry—a platform, made of rough boards, is strutted up from below parallel to the plane formed by the laths, and at about an inch below them. Mortar is then laid in from above over the platform and between and over the laths, to a thickness of from $2\frac{1}{2}$ inches to 3 inches, and is forced in under the laths, and under the joists and girders. The mortar, being gauged, as plasterers term it, or rather, in great part composed of plaster of Paris, soon sets sufficiently to allow the platform to be removed onwards to another compartment, until the whole ceiling is formed. The plaster ceiling thus produced is, in fact, a strong slab or table, in the body of which the batten-laths which hold it up are incorporated, and in the back of which the joists, from which the mass is suspended, are embedded. The finishing coat of plastering is then laid on. Such a ceiling will resist any fire that can act upon it from below, under ordinary circumstances; and it would be difficult for fire to take such a hold from above as to destroy the joists to which a ceiling so composed is attached, the laths and the under side of the joists being alike out of its reach; and consequently such a ceiling alone would diminish the danger from fire, although the floor above the joists were laid with deal boards.

oring terials. A boarded floor, however, in Paris is a luxury not to be found in the dwellings of the labouring classes, nor, indeed, are boarded floors to be found in any dwelling-houses but those of the more costly description. Whether the proposed surface is to be boarded or not, however, the flooring joists are covered by a table of plaster above, as completely as they are covered by a plaster ceiling below. Rough battens, generally split and in short lengths stout enough to bear the weight of a man without bending, are laid with ends abutting upon every joist, and as close together as they will lie without having been shot or planed on their edges. Upon this rough loose floor, mortar of nearly similar consistence to that used for the ceilings is spread to a thickness of about three inches; and as it is made to fill in the voids at the ends and sides of the floor-laths upon the joists, the laths become bedded upon the joists, whilst they are to some extent also incorporated with the plaster. The result is a firm floor, upon which, in ordinary buildings, paving-tiles are laid, bedded in a tenacious cement. It must be clear that the timbers of a floor so encased could hardly be made to burn even if fire were let in between the floor and ceiling. But it has been already stated that the practice of making these incombustible floors is connected with the use of walls which have no timber laid in them bedwise, and that the timber enclosures employed instead of walls, and the internal partitions, are rendered practically incombustible, whilst the wooden staircase which economy dictates to the Parisian builders—the freestone which is used in building walls being altogether too soft for the purpose—is also rendered, in the manner already shown, almost unassailable by fire.

It may be remarked with reference to the employment of any substance such as cinder, being of the nature of pozzuolana, or volcanic scoria, in mortar, to form a floor in the manner above described (about 3 inches thick), that as all such mortars expand in setting, the walls of buildings may be forced out by the expansion of the plaster floors, if the whole surface of the floor in any story be at once covered with the mortar. A margin of 4 or 5 inches on every side should be left void until the expansion has taken place, when the floor may be completed with an assurance of close joints, and without injury to reasonably stable walls. E... of floors.

When a boarded floor is required, as the surfaces of the true joists lie under the mortar, a base for the boards is formed of what English carpenters would call stout fillets of wood, about $2\frac{1}{2}$ inches square, ranged as joists, and strutted apart to keep them in their places, over the mortar table, to which they are sometimes scribed down, and that to these fillets, or false joists, the flooring boards are secured by nails; so that in truth the boarded floor is not at all connected with the structure of the floor, but is formed upon its upper coat of plaster. The wooden floor thus becomes a mere fitting in an apartment, and not extending beyond the room the floor might burn without communicating fire to the stairs, even if the stairs were readily ignitible.

The practice now in Paris, in respect of floors, is to form the structure of wrought iron joists rolled to the form known with us as I, T, and I iron, and to fill in with the same strong plaster between, below, and above the iron, and so to form a slab of plaster from 6 to 8 inches thick, according to the bearing and the depth of the iron bars—the bars being enveloped in the plaster; and the ceiling is formed as before described by laths resting on the lower flanges. In order to lighten the weight of the solid plaster, earthen pots have been placed between the joists and the spaces filled up with the mortar. Floors iron

The necessity which arises with us of dividing the upper stories of houses into more rooms, as bed-rooms, than are commonly required in the lower stories, will be made an objection to any process that would render the partitions heavier; but it is not in the upper stories that the lathed and plastered partition is most dangerous in respect of fire. Generally the stairs may be enclosed by solid partitions throughout almost the whole height of an ordinary dwelling-house without occasioning any inconvenience as regards the greater weight of such a partition; and generally, too, the partition which divides the front from the back rooms of such houses may be carried up throughout the whole height of a house without removing the bearing, if the house be judiciously disposed. But even if a partition rest upon a beam or girder, a very slight addition to the scantling of the timber will make up for the additional weight which the filling in of the partition would involve, if the materials of the core be well chosen; and it is well known that a piece of timber placed over a void as a bressummer, and carrying a wall, resists the action of fire for a long time, and the longer if it be of oak or other hard wood. It is not necessary, however, that the timber employed in parti- Upper partiti.

tions and enclosures should be of oak; though it is desirable that main bearing timbers, in situations which render them most liable to be exposed to the action of fire in the event of casualty, should be of such timber rather than of fir; but the quarterings, or partition timbers, which the plaster concrete wholly encases, may be of fir as safely almost as of oak.

ring. The core used in Paris consists for the most part of chips and spalls arising in the process of dressing the soft free-stone which is the main constituent of the walls of most buildings in that city. Almost any hard material, however, will furnish rubble fit for the purpose, which must be angular and irregular in form, so as to allow the mortar to pass freely through the rubble, and embed it all. Rubble of brick material, as broken burrs, or even of old bricks freshly broken, will answer very well; but if brickbats or shreds of plain tiles be used, care must be taken in packing not to bring flat beds together, or the mortar will not pass through and make a perfect concrete. Rubble of almost any kind may be used; but the kinds of stone which are themselves concretions, and present rough surfaces upon the fracture, are the best, while schistose or scaling slaty stones are the worst for the purpose. But there is no better substance for coring partitions upon the plan described than clay burnt into a kind of brick rubble.

The same process applied to external enclosures will justify the use of timber in their structure in situations and under circumstances in which it may be properly prohibited when the timber is merely lathed and plastered, or even brick-nogged, for brick-nogging adds nothing, as already remarked, to the strength of a partition or an enclosure, but rather takes from it, being itself a source of infirmity. But chimneys and their flues, with their congeners, stoves and furnaces, ought not, under any circumstances, to be formed in an enclosure in which timber is employed as a part of the structure.

Under some circumstances, again,—that is to say, when any street of a town is so wide and the buildings to be built fronting it are to be of such small elevation, as to make the communication of fire from one side to the opposite side practically impossible, if the buildings adjoining laterally are effectually separated from one another by sufficient walls, party or otherwise, and these project before the outside faces of the front and back enclosures so as effectually to prevent fire from passing round them,—the temperature of dwelling-houses may be much more easily maintained and regulated if the outside surface be boarded. Weather-boarding is a safe and economical, as well as a neat, wholesome, and equable outside casing for the fronts of a dwelling-house, if the boarding be backed up solidly, and the timber quarterings necessary to secure it be properly filled in between and behind with brick or stone work, or with rubble and concrete in the manner already described. Brickwork builds up badly with the raking braces of timber-framed enclosures, and the concrete described would not be so perfect with weather-boarding on one side as if the mortar were thrown in from both sides; but raking braces are less essential to enclosures which are filled in and backed with a heavy body of brick-work or concrete, than when mere lathing or even brick-nogging is to be employed on the inside. A 9-inch brick wall may, indeed, be very well built up with framed quarterings without raking braces, if the work be built between and around the quarterings, carrying, that is to say, the inner half-brick before the inside faces of the quartering, and so as to show on the inside a plain brick wall.

Building Trades.—The artificers whose trades properly belong to the builder's business are the digger or excavator, bricklayer, mason, sawyer, carpenter, joiner, cabinetmaker, slater, plumber, plasterer, modeller, carver, glazier, smith, founder, ironmonger, gasfitter, painter, and decorator. In this order the works of the trades will be described, and we now proceed to the ordinary routine of the practice of building. The two publications which should be noticed here as comprising more detailed references to these trades are Gwilt's *Encyclopædia of Architecture*, 8vo, 1869, edited by Wyatt Papworth; and Cresy's *Encyclopædia of Civil Engineering*, 8vo, 1861,—these will not, therefore, be noticed in the list at the end of each trade.

Foundation.—The architect having furnished the specification and working-drawings of his design, the first step is to prepare the foundation; and as this relates to the bricklayer as well as to the mason, we say what is necessary respecting it here. Much in this particular, it is evident, must depend on localities. It is not of so much importance that the ground be hard, or even rocky, as that it be compact, and of similar consistence throughout; that it be so constituted as to resist entirely and throughout, or yield equally to the superincumbent weight. But in the ordinary processes of building little requires to be said of the artificial preparation of foundations beyond the notice of it already given. When a good, hard soil is easily accessible, as solid gravel, chalk, or rock, we have nothing to do but to remove the surface mould, dig to the sound bottom, and at once to put in the footings. On softer ground it was usual to employ footings at least double the width of the wall, and frequently more; but since the invention, or rather revival, of the use of concrete, this is seldom or never done. In this case, or when the ground is a deep clay, be the material used what it may, it should at least go so deep as not to be affected by change of temperature, or the rising and falling of springs, as the alternate shrinking and swelling of the ground must affect the building. Frost seldom penetrates a foot into the ground in this country; but in clay soils, fissures, the consequences of drought, are found 3 feet and more in depth. The basis should, therefore, be below this point in such a stratum. If the ground be springy, it should be drained, if possible; if not, a foundation should be made with concrete as low as the lowest level of the water; or if very deep or boggy, piles must be used. The plan of building on sleepers and planking, so common some years ago, is very bad, as they rot after a time, and the building settles in all directions, as the greater weights crush the decayed timbers sooner than do the lighter portions of the building. Where ground is alternately wet and dry, the best timber soon decays; even piles should always be kept in the water. The use of concrete, except in very peculiar cases, has entirely superseded every other artificial foundation. It may be defined as a sort of rough masonry, composed of broken pieces of stone or gravel, cemented together with lime prepared in various ways, and thoroughly mixed with it, and not laid by hand but thrown at random into the trenches, to form the depth required.

Foundation. Planking. Concrete.

Any hard substance, broken into small pieces, will make good concrete. That most used is gravel, or ballast. This should not be too fine, as the sand which may be in it will mix with the lime and form a sort of mortar, assisting to cement the stones together. If broken stones or masons' chips are used, it is desirable to add some sharp sand with them. The general rule is, that no piece of stone should exceed a hen's egg in size. In this country the lime is generally ground, which is bad, as the core or unburnt portion is ground up with the good lime. About one-sixth part of lime is generally used; chalk lime should not be used in a damp situation. It is mixed with the ballast by scattering it among the stones, and turning it all over with a shovel, water being at the same time thrown upon the mass. It is then, while hot, filled into the trenches, sometimes by shooting from stages

erected for the purpose 6 or 8 feet above the work; but this process has been very justly censured as uncertain by eminent engineers, who prefer to put it in layers of not more than one foot in thickness, and to level each course, ramming it down thoroughly. When the lime is too hastily put into the trenches, and has not had time to be thoroughly slaked, the process will continue, and the mass will puff or swell and sometimes cause considerable mischief. Wing walls of bridges have been thrust out by this means. To make a solid concrete all the interstices of the gravel should be filled with the sand, and the lime and the water will be absorbed without any increase of bulk. In France the lime is first made into a paste, and the mixture is then called *béton*, not concrete; this is a more scientific process for obtaining a sound substance. In some experiments made by the Architectural Publication Society, where the materials were carefully mixed, no change took place in the bulk; but some experimentalists, practical men, and writers differ on this point, and assert there is a loss of one-seventh in bulk when set. The lime, if it can be procured, should be hydraulic; and concrete is much improved by the addition of the volcanic sands. French authors recommend, as good proportions, one-fifth hydraulic lime, one-fourth pozzuolana, one-eighth sharp sand, and the rest broken stone or gravel; or 20 per cent. hydraulic lime, the same of trass, the same of sharp sand, 15 per cent. of gravel, and 25 per cent. of broken stone. Perhaps the very best concrete is made of a simple mixture of gravel, sand, and Portland cement. It is unnecessary to enter into the details of foundations in water, as this but seldom comes within the ordinary builder's province.

xcavator. *Digger or Excavator.*—The digger works with a pick-axe and a spade or shovel. With the pick-axe he breaks down the soil if it be hard or very stiff, and throws it out with the shovel; but compacted sand and alluvial soil are spitted and thrown out with the spade alone, without previous breaking down. When rock occurs in a foundation, the assistance of the quarryman is requisite to cut through or blast it, as the occasion may require. The digger should be required to produce a perfect level in every direction, and especially in trenches for walls; nor may this be done by replacing loose matter, but the level must be produced on the solid or undisturbed bed. A good excavator will dig and throw out, of common soil, into a basket or wheelbarrow, 8 or 10 yards per diem; but of stiff clay or firm gravel not more than 6 yards.

When the excavation has to be dug to a depth about the height of a man it will be necessary to strut the ground to prevent its falling in, especially if it be of a sandy, loose, or watery nature. This is done by placing on each side of the cutting upright planks against the soil, which may be either open or close, according to the quality of the soil, and against these one or more horizontal waling pieces secured by horizontal cross pieces or struts, and wedging up as necessary. On these struts are formed the landings or stages on which the lowest workman throws the soil he digs up, which is then again thrown up by a second man to another stage or to the surface, according to the depth. Sometimes the soil is hoisted in baskets or tubs raised by a windlass worked by hand, or by a horse-run. When the work has been executed for which the excavation was prepared, the digger has to fill in over and around it, carefully ramming the soil to prevent inequalities on the surface by the soil sinking, and to prevent water soaking in which might affect the foundations.

Brickwork.

Tools. The tools and implements employed by the bricklayer are the trowel, plumb-rule, rod, level, square, bevel, line-pins and lines, raker, jointer, crow-bar, pick-axe, and rammer, together with a hod and spade for his labourer. Besides these there are sundry others, as an axe, saw, and rubstone, used in cutting and gauging bricks, and some which are peculiar to tiling and paving. A pug-mill and screens for mixing and tempering mortar, and tubs and pails for water, are also auxiliaries of great importance.

In ordinary practice the bricklayer's scaffolds are carried up with the walls, and are made to rest on them. Having built up the walls as high as he can reach from the ground, he plants a row of poles, which vary in height from 30 to 40 and even 50 feet, parallel to and at a distance of about 4 feet 6 inches from the walls, and from 10 to 12 feet apart. To these, which are called standards, are attached by means of cords other poles called ledgers, horizontally and on the inside, with their upper surface on a level with the highest course of the wall yet laid; and on the ledgers and wall short transverse poles, called putlogs or putlocks, are laid as joists to carry the floor of scaffold boards. These putlocks are placed from 4 to 6 feet apart, according to the length and strength of the scaffold boards; and the ends which rest on the walls are carefully laid on the middle of a stretcher, so as to occupy the place of a header brick, which is inserted when the scaffolds are struck after the work is finished. On the floor of the scaffold thus formed the bricklayer stands, and the materials are brought up ladders to him by labourers in hods from the ground below; or they are hoisted up in baskets and buckets by means of a pulley-wheel and fall; or by the horse-run, which is more generally used, formed of a level pathway in which the horse moves, drawing up the load by the intervention of snatch blocks and guide wheels; or by the now usual hoisting-machine, worked by men, horses, or steam-power. The mortar is placed on ledged boards about 3 feet square, at convenient distances; and the bricks are strewn on the scaffold between the mortar boards, leaving a clear way against the wall for the bricklayers to move along unobstructedly. The workman then recommences the operation of bricklaying, beginning at the extreme left of his course, and advancing to the right until he reaches the angle or quoin in that direction, or the place where his fellow-workman on the same side may have begun. Thus he goes on with course after course until the wall is as high as he can conveniently reach from that scaffold, when another ledger is tied to the poles, another row of putlocks laid, and the boards are removed up to the new level. The ledger and most of the putlocks, however, remain to give steadiness to the temporary structure, and so on to the full height of the wall, the poles being pieced out by additional lengths as may be required. If a scaffold be very much exposed, and run to a great height, it must be braced. This is done by tying poles diagonally across on the outside to the standards and ledgers, and it may be further secured by tying the ends of some of the putlocks to the ledgers; but an outside scaffold should never be attached in any way to the building about which it stands. A scaffold should never be loaded heavily, as well on account of the work as of the scaffold itself; for the putlocks resting, as they do, on single bricks, in a green wall, they exert an injurious influence on it, which every additional pound weight on the scaffold must necessarily increase, and the putlocks themselves are liable to be bent or broken. A constant and steady supply of bricks and mortar on the part of the labourers, without overloading the scaffold at any one time, should be strictly required. Sca-

The suspended scaffold is a very ingenious contrivance, by which pointing and other external repairs of a house can be performed at a comparatively small cost, and without interference with the thoroughfare. The front can also be painted by the same means. Although known at least Su-

before 1825, it is only of late years that this scaffold has been much used. A couple of planks are secured side by side to form a platform, which is guarded by a railing all round to prevent the workmen falling off. To iron bands are secured pulleys and ropes, passing over other pulleys made fast to two or more beams projecting out of the upper windows, or secured to the roof-timbers, by means of which the workmen employed can raise or lower the scaffold to any position where it is wanted to get access to the work to be done.

Brickmaking.—The manufacture of bricks forms the subject of a separate article. See p. 279 of the present volume.

Mortars and Cements.—A few observations on the composition of mortars and cements for bricklaying will be necessary here. Mortar is of two kinds,—common mortar, or that mixture of lime and sand ordinarily used in building; and hydraulic mortar, or that which will set under water. Cement is a name given to the produce of certain argillaceous stones, after calcination, which will set rapidly in the air, becoming a hard adhesive substance in a short time, and will also set under water, both without admixture of any other substance. The name is given, too, to certain artificial imitations of these substances, possessing the same properties; and besides, to various bituminous or oleaginous compositions, used in building for similar purposes.

Pure lime, which is an oxide of a metal called calcium, does not exist in a natural state. It is, however, found abundantly in the conditions of carbonates and subcarbonates, in chalk, and in the various other descriptions of limestones. Its chemical qualities and analysis will be described under the proper headings in this work. Limes are generally classed, since the publication of the work of Vicat, as—(1) rich limes, (2) poor limes, (3) limes slightly hydraulic, (4) hydraulic limes, and (5) eminently hydraulic limes. In treating of mortar we have to deal with the first two of this division. The first operation is to drive off the water, which all limestones contain in a greater or less degree, and the carbonic acid gas, which is done by calcining or burning in a kiln at red heat; this must be kept up for several hours, care being taken to avoid any approach to vitrification. By this process it is slightly diminished in bulk, loses nearly half its weight, and becomes caustic lime. The lime is next converted into a hydrate by a process called "slaking," or throwing pure water over it from time to time till it hisses and cracks with considerable force and some noise, gives off a large quantity of hot vapour, and falls into a powder. The rich limes, which are the purest oxides of calcium, increase to double their bulk in the process. The poor limes swell to a much less degree. The hydrates thus formed absorb water, and easily take the form of a paste. They contain rather less than one-third water to two-thirds lime. In this state, if treated with pure water, frequently renewed, every particle of the rich limes, and very nearly the whole of the poor limes, will be taken up in solution. In the process of slaking too much water should not be used, as it "drowns" the lime, according to the expression of the workmen. When in the form of paste it begins to absorb carbonic acid, which is always present in air in considerable quantities, and gradually to crystallize again, and so to harden. If the air be excluded from the hydrate of pure lime, it may be kept for almost any length of time. Alberti (lib. ii. cap. 11) says that he once discovered some in an old ditch, which from certain indications must have been there 300 years, and was as soft as honey or marrow, and perfectly fit for use.

The rich limestones give a white lime, which easily slakes, and increases in bulk; but it is curious that though the stones differ so much in outward appearance and in texture, the lime, if they be well burned, is the same. The softest chalk and the hardest rag-stone or marble yield an equally good lime, the calcium which they contain being the same mineral. But as chalk generally contains water, irregularly distributed in some places and not in others, and as it does not exhibit the change that marble or stone does, it is frequently unequally burned, and therefore slakes imperfectly. It is said by Higgins (*Mortars and Cements*, p. 29), however, that lime made from chalk absorbs carbonic acid more rapidly than that made from stone; but experience does not seem to warrant this conclusion. Poor limestones are those which contain silica, magnesia, manganese, or metallic oxides. In consequence of this they are more liable to vitrify in burning, and do not slake so freely. The lime is generally of a browner colour than that from rich limestones, which is said to be a proof of the presence of the above-named metallic oxides. If, however, they be ground so as to facilitate the slaking of every particle, and if used immediately being made up, poor limes produce a mortar which becomes harder than that from the rich limes, and which resists water better. In fact, works where the latter have been used have been found to fail entirely by the action of running water, which, as before has been said, will continue to remove the whole of a rich lime particle by particle.

Poor lime stones.

It is found that the mixture of some kind of hard matter in particles or granules facilitates the setting of mortar, and renders it harder and more adhesive than when used alone, besides the saving of limestone and expense of burning. The harder this material and the sharper the particles the better, as the brick or stone has always some irregularities on the surface, into which these angles or sharp points may enter, and form what is called a key. The substance most generally used is sand, which is classed as river-sand and pit-sand. The former is usually preferred, as it is more free from earthy matters, particularly soft loams or clay. Mortar made with sand containing one-seventh or one-eighth part of fat clay moulders in winter like marl,—a circumstance which proves the propriety of freeing from clay the sand used in mortar. If pit-sand be used it should be well washed. Scarcely any material is better than crushed quartz, or flint, from the sharpness of the angles of the particles; in fact, it is said that very sharp sand, with an inferior lime, will make a more adhesive mortar than soft sand with the best lime. The practical mixing of mortar will be noticed further on. Where sand is scarce, other materials are sometimes used, the principal and cheapest of which is burned clay. The Romans used this extensively in the form of pounded tile. At present the custom is to throw up clay mixed with fuel in loose heaps, to burn it slowly, and then to grind it in a mill with a proper quantity of lime. The French writers at one time asserted that burned clay, if not equal to pozzuolana, was very nearly so; and large quantities were used as hydraulic mortars at various public works. Where the water was fresh, as at Strasburg, the work stood very well; but where these mortars were exposed to the action of sea-water, they failed and went to powder in three or four years. Vicat gave great attention to the subject; and though he attributed much of the fault to the imperfect carbonization of the materials, it appears with but little doubt there is some inherent difference between the pozzuolanas and other volcanic products and those produced artificially. After long investigation, Vicat was of opinion that this failure was due to the quantity of hydrochloride of magnesia always present in sea-water; but in what way this affected the burned clay and not the volcanic products he was unable to explain.

Sands.

Other materials.

Burned clay.

A very excellent mortar, much used by engineers in

tunnels, is composed of one part of moderately hydraulic lime, one part of coal ashes, one part of burned clay, and two parts of sharp sand. The vitrified refuse of furnaces, called slag, and the scoriæ from the iron-works, have also been crushed and used instead of sand; and with lime, slightly hydraulic, produce good mortar. The former is preferred to the latter, as having sharper and harder particles, and containing much less iron. Coal cinders have been used, and seem to have some hydraulic properties; they should, however, be employed with caution, for it is considered they make the lime "short." Wood cinders are too alkaline to be used with safety.

The vitrified and calcined products of volcanoes make most excellent materials for mortars, particularly where required to be eminently hydraulic. The principal of them is the pozzuolana, which abounds in Italy. It is called so from being found in great abundance at Pozzuoli, near Naples, and is, in fact, the basis of all the best Roman mortars, ancient as well as modern. It is usually sent to England from Civita Vecchia. It varies in colour from reddish brown to violet red, and is sometimes greyish; it has a roughly granulated appearance, and sometimes resembles a cinder in texture, and has frequently a spongy appearance. Acids have little effect on it, and it is not soluble in water. A similar earth is found in the centre of France. But one long known in this country comes from the village of Brohl, near Andernach, on the Rhine; this is called tarrass or trass. These materials have a wonderful effect in rendering even the rich limes eminently hydraulic, and in less proportions improving the hydraulic limes. Vicat says, these mortars begin to set under water the first day, grow hard in the third, and in twelve months are as hard as the bricks themselves. The mixture of common lime with these materials, according to the French writers, should be 1 of pounded lime to $2\frac{1}{2}$ of pozzuolana, or to 2 of trass; or 1 of lime to 1 of sand and 1 of pozzuolana.

In addition to the hydraulic limes, which have been thus described, there is a peculiar class of stones, which, when burned and pulverized, may be used as mortar, without admixture of sand or any similar substance; and which will not only set rapidly under water, but will acquire an unusual degree of hardness and tenacity. These are called natural cements. Mr Parker is supposed to have been the inventor; at any rate, that gentleman took out a patent about sixty years ago for what he called Roman cement. His materials were the argillo-calcareous nodules, or septaria, found in the Isle of Sheppey, and commonly called bald-pates. They contain about 70 per cent. of carbonate of lime, about 4 per cent. of oxide of iron, 18 per cent. of silica, and 6 or 7 per cent. of alumina. The process is simply to break the stones into small pieces, and burn them in running kilns with coal or coke; they are then ground to a powder, and headed up into casks for use. The success of Parker's cement led to experiments in other places, and the same process was carried on with other argillo-calcareous nodules, as the septaria at Hawick; those in Yorkshire, which produce the cement called Atkinson's; and those in the Isle of Wight, which produce the Medina cement. Similar substances were also discovered, and the same processes carried on in France and in Russia. All these cement-stones effervesce with acids, and lose about one-third of their weight in burning. Parker considered that the more the stones were burned short of absolute vitrification the better; but this is not the practice in the present day, though, no doubt, sound in theory. When taken from the kiln these stones will not slake without being pulverized; and if kept dry, and not exposed to the air, the cement will be good almost any length of time; but it rapidly absorbs both water and carbonic acid if not carefully closed up, and falls back into a state of subcarbonate, from which it is said it may be recovered by fresh burning, but it is doubted whether it is ever so good as on the first calcination. The great utility of these cements, and the expense of obtaining the stone, induced manufacturers to endeavour to discover some method of making an article by artificial means which should resemble the natural cements. Mr Frost seems to have been the first who attempted it on a large scale; but though he was assisted by the science of General Pasley, the results did not come up to the expected standard. Of course, the object was to produce an argillo-calcareous substance containing the same chemical qualities as the natural nodules, which might be burned in kilns as they are. The attempt to combine argil in the form of burned clay, to be mixed with lime instead of pozzuolana, had partially failed, as has been stated above. The experiments conducted by General Pasley, and by Vicat at Meudon in France, were all based on the principle of mixing together, in a mill, with a quantity of water, masses of chalk and clay, just as the brickmakers do for the production of malm bricks, but in the proportion of about four of the former to one of the latter. The fluid mixture is run out into shallow receivers, and when dry is cut into small blocks or lumps, and burned exactly as the natural nodules are. The difficulty was to give the materials the full degree of calcination short of vitrification. A successful result seems to have been at last attained by the inventors of the Portland cement, so called from its near resemblance to Portland stone in its colour. It not only possesses the property of setting more quickly, and has greater powers of cohesion than the natural cements, but it may be used with a superabundance of water in the form of grout, which they cannot be; above all, it seems to resist the action of sea-water beyond all others; and it is proof against water when used as a mortar in setting brickwork, and in the composition of concrete for foundations. It also forms a very superior cement for plasterer's work. A prepared patent carbonate (Westmacott's patent) is used in combination with chalk, grey, and all other limes. All the carbonic acid being removed from the lime in its burning, 75 per cent. of this acid is restored by its mixture with the prepared patent carbonate, and its induration immediately commences, instead of the lime gaining the carbonic acid by atmospheric influence through a lengthened period. It is used as a quick stucco for rapid plastering; and as a carbonated lime for external use it is in the course of a few days converted into a stone mortar.

Selenitic mortar is the name given to a composition lately invented by Major-General Scott. He was the first to observe, about eighteen years ago, that a limestone capable of conversion by burning into a hydraulic lime might furnish a good cement by simply allowing a small portion of sulphuric acid gas to pass into the kiln during the burning of the lime. Having found difficulty in carrying out this process, he now mixes with the water used in the preparation of the mortar a small quantity of sulphate of lime (*i.e.*, plaster of Paris, or gypsum) or green vitriol. It has the advantage, when used for plastering, of allowing the setting coat to be applied in forty-eight hours after the first coat has been put on. This mortar is said to save half the lime, is four times as strong, and sets in one quarter of the time required by common mortar. The lime will take six parts of sand, and is said to be an excellent substitute for Portland cement for concrete at less cost.

Asphalt, or mineral pitch (see ASPHALT), has lately come into extensive use for paving, for covering the backs of arches, or rendering the walls of basements where wet is likely to soak through, also as a damp-course over the footings of walls to prevent the rise of damp, and for lining cisterns and tanks to prevent the escape of the fluid. The best qualities are the Val de Travers and the Seyssel,

both obtained from France. In using asphalt for paving, a bed of concrete, made of the best hydraulic lime, is first prepared, and made fair at top by a rendering of similar mortar. The asphalt will not dissolve with heat by itself, but will calcine in the caldron. A small quantity of pure mineral pitch is therefore first put in; when this is hot the asphalt is added, and soon dissolves; a quantity of powdered stone-dust is then stirred in, and a small portion of quicklime. The mixture in its melted state is then laid on the bed of concrete (which must be quite dry), and spread close and fair, some sand being sprinkled over the top and well trowelled in. The best proportions are said to be about 2 pints of mineral pitch to 10 ℔ of asphalt and one-fourth bushel of stone-dust. Another method of forming a paving is to place on the concrete a layer about 3 inches in thickness of hot asphalt in powder, and then to ram it down with hot iron rammers, until it has come to its proper consistency; it is then finished as usual. This has been lately much used for roadways in the city of London and elsewhere. The same material has been compressed into tiles about 6 inches square; and these laid on a good foundation. A very inferior imitation is made by mixing a quantity of sharp sand with gas-tar, heated in a caldron, and then adding some quicklime. This may do for rendering walls, &c., to keep out wet, but it is of very little use as paving. Gravel coated with tar, and then laid and set in tar, rammed down, and sanded over, makes a very good pavement for ordinary footpaths.

As before noticed, particular attention must be paid to cleansing the sand to be used for mortar of every particle of clay or mud that may adhere to or be mixed up with it. Sea-sand is objectionable for two reasons: it cannot be perfectly freed from a saline taint, and the particles are moreover generally rounded by attrition, caused by the action of the sea, which makes it less efficient for mortar than if they retained their natural angular forms. Lime should not be slaked until the moment it is to be mixed up with the sand in mortar, but the sooner that is done after it is burnt the better. The proportion of lime to sand generally taken, and the best, is one to three; but if both the materials be of good quality, that is, if the lime slake freely, and become a fine pungent impalpable powder, perfectly clear from argillaceous or any other foreign matter, and the sand be clean and sharp, one part to four is enough; more is injurious. The ingredients should be well mixed together, and with just as much water as will suffice to make the compound consistent and paste-like. Of late years, in lieu of sand, burned clay, as above noticed, has been much used in localities where it is difficult to obtain the former material. This is ground up with lime in a mill, but unless very great care is taken in its manufacture the result is a very poor substitute for sand and lime mortar; and brick and lime rubbish have also been used in like manner, with an equally inferior result. Rain or other soft water should be used for the purpose of making mortar, and not spring or hard water, though any other may be preferred to what is brackish even in the slightest degree. Higgins recommended that lime-water should be used in preference to pure water. A quick-setting cement, such as those which are commonly used in building in England, and known as Parker's or Roman cement, and Portland cement, can only be mixed or gauged as it is required for use. A bricklayer will keep a labourer fully employed in gauging cement for him alone. It is mixed with sand in the proportion of from about two or three to about five or six of sand, to one of the cement, according to the quality of the latter; and the labourer as he gauges on one board supplies the mixture to the bricklayer fit for use on another board, a spadeful at a time; it must then be applied within half a minute, or it sets and is spoiled and wasted, for it should never be worked up again.

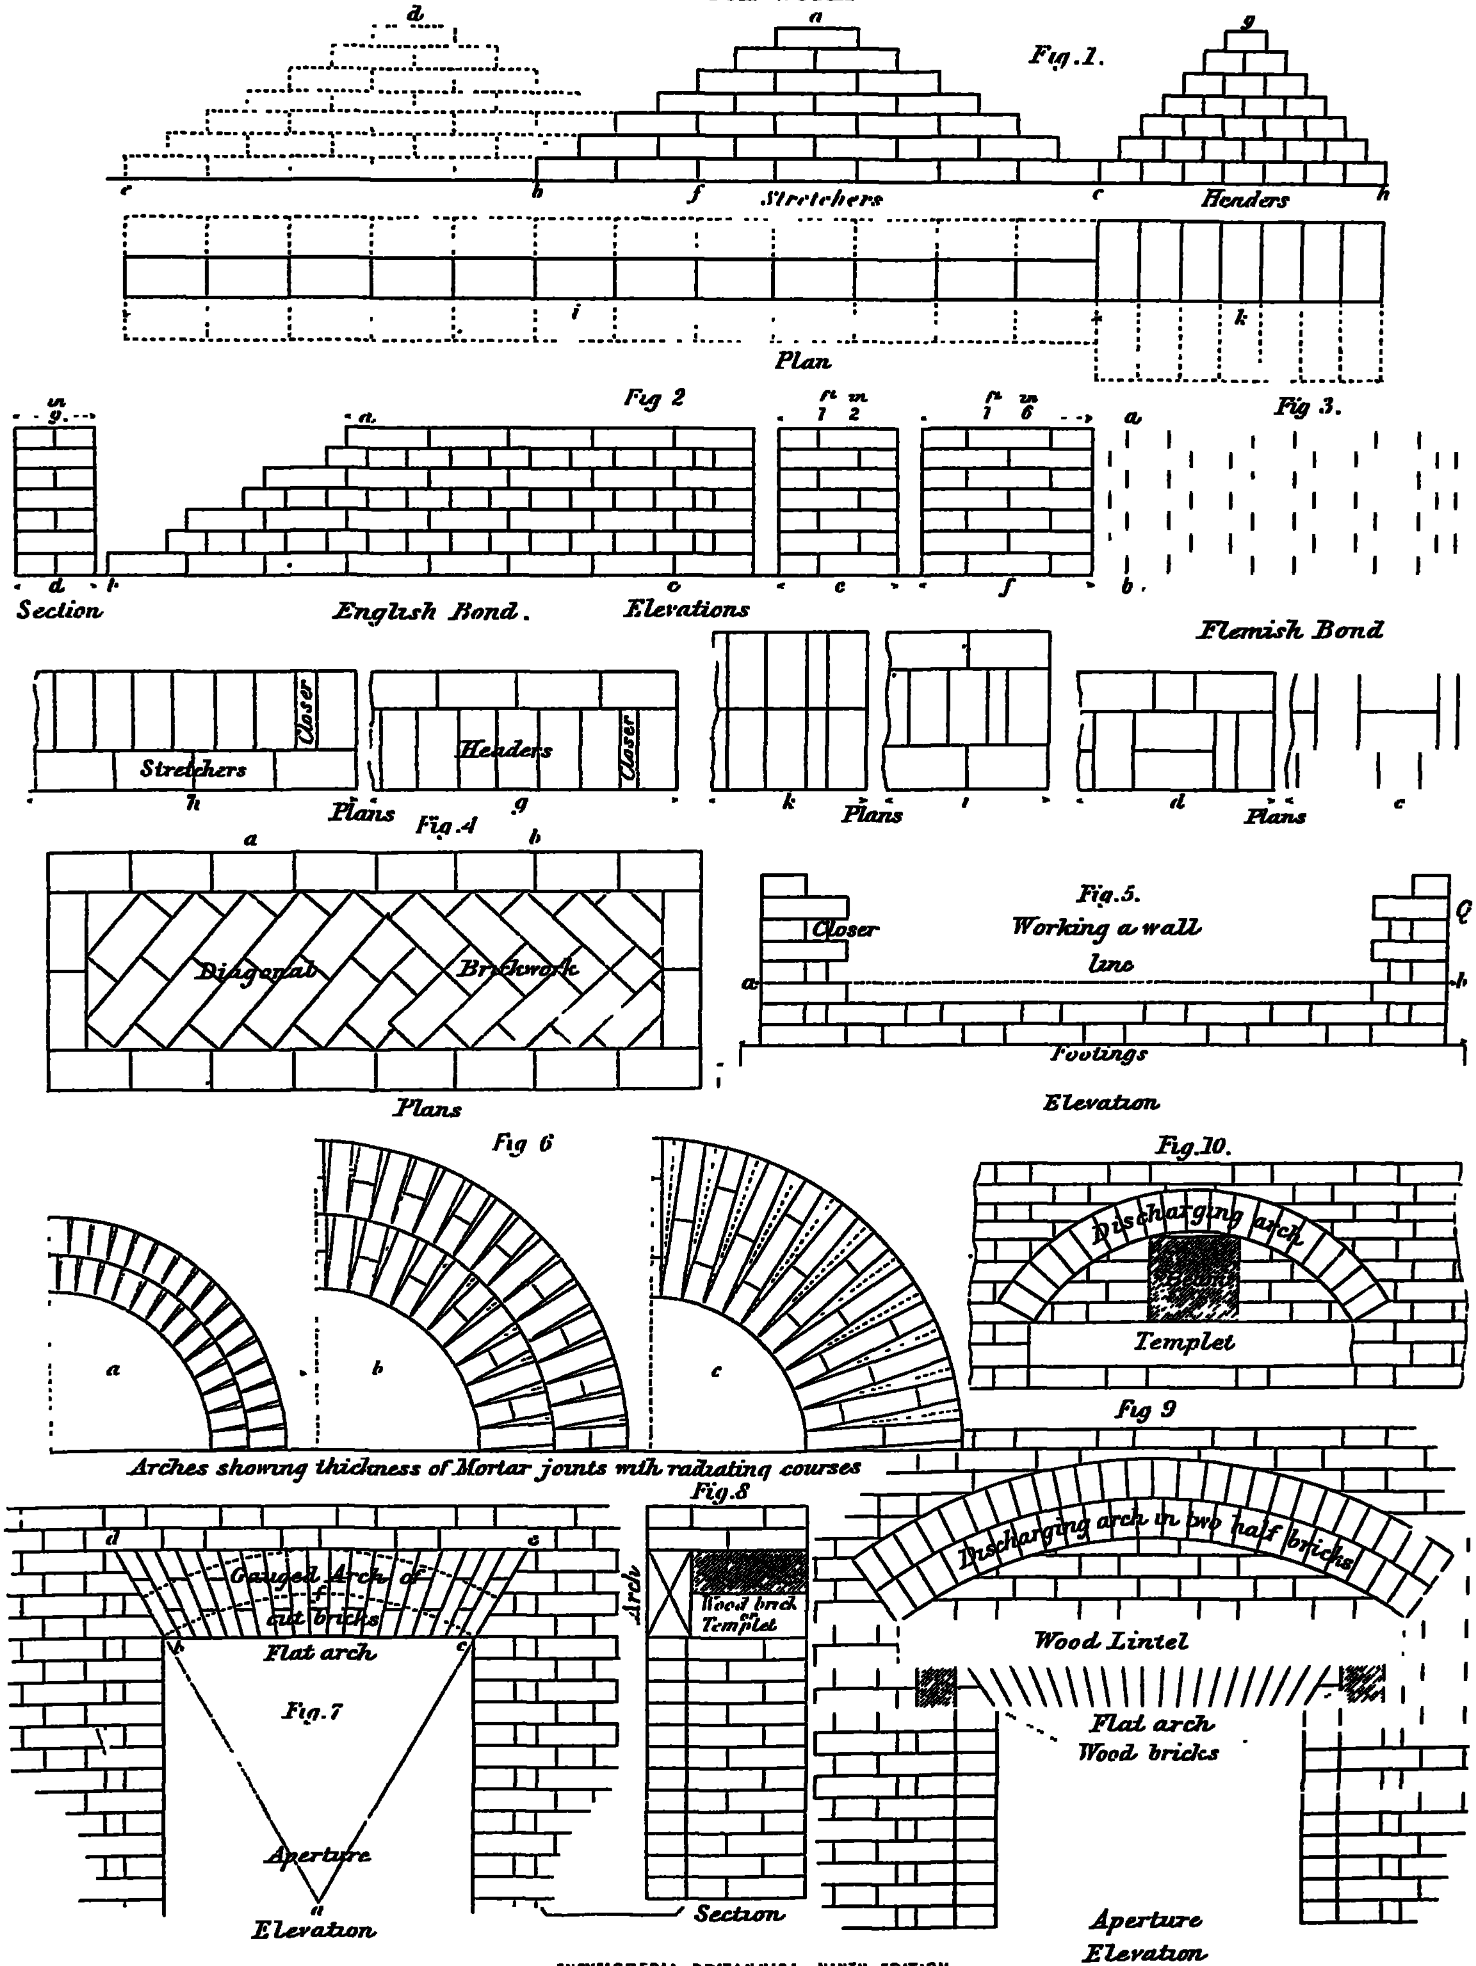
The average size of bricks in England is a fraction under 9 inches long, $4\frac{1}{2}$ inches wide, and $2\frac{1}{2}$ inches thick; and in consequence of this uniformity of size, a wall of this material is described as of so many bricks in thickness, or of the number of inches which result from multiplying 9 inches by any number of bricks; a 9-inch or one-brick wall; a 14-inch or one-brick-and-a-half wall ($13\frac{1}{2}$ inches would be more correct, in fact, for although a joint of mortar must occur in this thickness, yet the fraction under the given size of the brick is enough to form it); an 18-inch or two brick wall, and so on. Brick walls.

The great art in bricklaying is to preserve and maintain a bond, to have every course perfectly horizontal, both longitudinally and transversely, and perfectly plumb (which last, however, may not mean upright, though that is the general acceptation of the term, for the plumb-rule may be made to suit any required inclination, as inward against a bank, for instance, or in a tapering tower); and also to make the vertical joints recur perpendicularly over each other, which is vulgarly and technically called keeping the *perpends*. By bond in brickwork is intended that arrangement which shall make the bricks of every course cover the joints of those in the course below it, and so tend to make the whole mass or combination of bricks act as much together, or as dependently one upon another, as possible. The workmen should be strictly supervised as they proceed with it, for many of the failures which have occurred may be referred to their ignorance or carelessness in this particular. The object of bonding will be understood by reference to the diagram, fig. 1, Plate XX. Here, it is evident, from the arrangement of the bricks, that any weight placed on *a* would (supposing, as we are obliged to suppose, that every brick bears equally, throughout its whole length, a stress laid on every part of it) be carried down and borne alike in every course from *b* to *c*; in the same manner the brick *d* is upborne by every brick in the line *e f*, and so throughout the structure. But this forms a longitudinal bond only, which cannot extend its influence beyond the width of the brick; and a wall of one brick and a half or two bricks thick, built in this manner, would, in effect, consist of three or four half-brick-thick walls, acting independently of each other, as shown in the plan at *i* in the diagram under fig. 1. If the bricks were turned so as to show their short sides or ends in front, instead of their long ones, certainly a compact wall of a whole brick in thickness would be produced; but the longitudinal bond would be shortened one-half, as at *g c h*, and a wall of any greater thickness, in the same manner, must be composed of so many independent one-brick walls, as at *k* in the plan before referred to. To obviate this, to produce a transverse, and yet preserve a true longitudinal bond, the bricks are laid in alternate courses of headers and stretchers, or of ends and sides, as shown in fig. 2, thus combining the advantages of the two modes of arrangement *a b c* and *g c h* fig. 1, in *a b c* fig. 2. Each brick in fig. 2 showing its long side in front, or being a stretcher, will have another lying parallel to it, and on the same level, on the other side, to receive the other ends of the bricks showing as headers in front, which in their turn bind, by covering the joint between them, as shown in the end of such a wall at *d*. Thus a well-bonded 9-inch or one-brick wall is produced. The end elevations of the same wall at *e* and *f* show how the process of bonding is pursued in walls of one and a half and two bricks thick, the stretcher being abutted in the same course by a header,—thus, in a 14-inch wall, inverting the appearance on the opposite sides, as seen at *e*, and producing the same appearance in an 18-inch wall, as at *f*. In the diagram

Bricklaying. Bonding. Plate XX.

BUILDING

BRICK WORK



W. & A. K. Johnston.

under fig. 2, at g, is the plan of a 14-inch wall, showing the headers on one side, and the stretchers on the other, and at h is the plan of the course immediately above it, in which the headers and stretchers are inverted; at k and i are shown in the same manner the plans of two courses of an 18-inch wall. This is called English bond. Thicker walls are constructed in the same manner by the extension of the same principle.

glish
d.

sers.

But a brick being exactly half its length in breadth, it is impossible, commencing from a vertical end or quoin, to make a bond with whole bricks, as the joints must of necessity fall one over the other. This difficulty is obviated by cutting a brick longitudinally into two equal parts, which are called half headers. One of these is placed next to a whole header, inward from the angle, and forms with it a three-quarter length between the stretchers above and below, thus making a regular overlap, which may then be preserved throughout; half headers so applied are technically termed closers, and are shown next the upright angle of the wall fig. 2, and the first joints inwards from the square ends by the headers in the plans at g and h. A three-quarter stretcher is obviously as available for this purpose as a half header, but the latter is preferred, because, by the use of it, uniformity of appearance is preserved, and whole bricks are retained on the returns. In walls of almost all thicknesses above 9 inches, to preserve the transverse, and yet not destroy the longitudinal bond, it is frequently necessary to use half bricks; but it becomes a question whether more is not lost in the general firmness and consistence of the wall by that necessity, than is gained in the uniformity of the bond. It may certainly be taken as a general rule, that a brick should never be cut if it can be worked in whole, for a new joint is thereby created in a construction, the difficulty of which consists in obviating the debility arising from the constant recurrence of joints. Great attention should be paid to this, especially in the quoins of buildings, in which half bricks most frequently occur; and there it is not only of consequence to have the greatest degree of consistence. but the quarter bricks used as closers are already admitted, and the weakness consequent on their admission would only be increased by the use of other bats, or fragments of bricks.

mish
nd.

Another mode of bonding brickwork, which may be supposed to have arisen from the appearance of the ends of a wall according to the former mode of arrangement (see e and f, fig. 2), instead of placing the bricks in alternate courses of headers and stretchers, places headers and stretchers alternately in the same course, fig. 3. The plans below this at c and d are of two courses of a 14-inch wall, with their bond, showing in what manner the joints are broken in the wall horizontally as well as vertically on its face. This is called Flemish bond. Closers are also necessary to this variety of bond; half bricks also will occur in both, but what has been said with reference to the use of them in the former applies even with more force to the latter, for they are more frequent in Flemish than in English, and its transverse tie is thereby rendered less strong. Their occurrence is a disadvantage which every care should be taken to obviate. The arrangements of the joints, however, in Flemish bond, presenting a neater appearance than that of English bond, it is generally preferred for external walls when their outer faces are not to be covered with some composition; but English bond should have the preference when the greatest degree of strength and compactness is considered of the highest importance, because it affords, as we have already noticed, a better transverse tie than the other.

o Flemish
nd
road

Mr W. Hosking was the first to notice (in the last edition of this work) that what is in England called Flemish bond is unknown in Flanders, and is practised in the British Isles alone. In Flanders, Holland, and Rhenish Germany, which are bricklaying countries, no kind of bond is found but what is known in England as English bond. But it has lately been noticed that the mediæval brick buildings in the north-east of Germany are worked in Flemish bond, or as it is there called "cross-bond;" and it is also to be seen at Brussels in work of about the end of the 18th century. Many of the buildings designed by Inigo Jones in England, and perhaps all of those by Sir C. Wren, are executed in Flemish bond, which name, it has been suggested, might have been derived from the word "flemishing" used by workmen, and thus applied to brickwork as meaning work better "finished off" than the other kind.

Herring-
bone wor

It has been attempted to improve the bond in thick walls by laying raking courses in the core between external stretching courses, and reversing the rake when the course recurs. This obviates whatever necessity may exist of using half bricks in the heading courses, but it leaves triangular interstices to be filled up with bats, as is shown in Plate XX. fig. 4. This represents the plan of 36-inch or three-brick wall with raking courses at a, between external ranges of stretchers, and lying on a complete course of headers, and at b a wall of the same thickness herring-boned; courses of headers would bed and cover this also, and, in the second course above, the raking or herring-boning would be repeated, but the direction of the bricks reversed. It will be seen that the latter demands, in addition to the triangular filling in bats at the outer ends of the diagonally placed bricks, half bricks to fill up the central line of interstices, rendering herring-boning more objectionable in that particular, though it has some advantages over simply raking, or thorough diagonal courses in other points. Neither mode should, however, be had recourse to for walls of a less thickness than three bricks, and that indeed is almost too thin to admit of any great advantage from it.

Walls to
be vertical
and level

Not second in importance to bonding is, that the brickwork be perfectly plumb, or vertical, and that every course be perfectly horizontal, or level, both longitudinally and transversely. The lowest course in the footings of a brick wall should be laid with the strictest attention to this latter particular; for the bricks being of equal thickness throughout, the slightest irregularity or incorrectness in that will be carried into the superimposing courses, and can only be rectified by using a greater or less quantity of mortar in one part or another, so that the wall will of course yield unequally to the superincumbent weight, as the work goes on, and perpetuate the infirmity. To save the trouble of keeping the plumb-rule and level constantly in his hands, and yet to insure correct work, the bricklayer, on clearing the footings of a wall, builds up six or eight courses at the external angles (Plate XX. fig. 5), which he carefully plumbs and levels across, and from one to the other. These form a gauge for the intervening parts of the courses, a line being tightly strained from one end to the other, resting on the upper and outer angles of the gauge bricks of the next course to be laid, as at a and b, and with this he makes his work range. If, however, the length be great, the line will of course sag; and it must therefore be carefully set and propped at sufficient intervals. Having carried up three or four courses to a level, with the guidance of the line, the work should be proved with the level and plumb-rule, and particularly with the latter at the quoins and reveals, as well as on the face. A smart tap with the end of the handle of the trowel will generally suffice to make a brick yield what little it may be out, while the work is so green, and not injure it. Good workmen, however, take a pride in showing how correctly their work will plumb without tapping. In work which is circular on the plan, both the level and the plumb-rule must be used, together with

a gauge-mould or a ranging trammel, for every course, as it must be evident that the line cannot be applied to this in the manner just described. For every wall of more than one brick thick, two men should be employed at the same time, one outside and the other inside; one man cannot do justice from one side even to a 14-inch wall.

aying ricks. Bricks should not be merely *laid;* every brick should be rubbed and pressed down in such a manner as to force the mortar into the pores of the bricks, and so produce absolute *adhesion.* Moreover, to make brickwork as good and perfect as it may be, every brick should be made damp, or even wet, before it is laid, especially in hot weather, otherwise it immediately absorbs the moisture of the mortar, and, its surface being covered with dry dust, and its pores full of air, no adhesion can take place; but if the brick be damp, and the mortar moist, the dust is enveloped in the cementitious matter of the mortar, which also enters the pores of the brick, so that when the water evaporates their attachment is complete. To wet the bricks before they were carried to the scaffold would, by making them heavier, add materially to the labour of carrying; in dry weather they would, moreover, become dry again before they could be used, and for the bricklayer to wet every brick himself would be an unnecessary waste of his time; boys may therefore be advantageously employed to dip the bricks on the scaffold, and supply them in a damp state to the bricklayer's hand. A watering-pot with a fine rose to it should also be used to moisten the upper surface of the last laid course of bricks preparatory to strewing the mortar over it. In bricklaying with quick-setting cements all this is of even more importance; indeed, unless the bricks to be set with cement are quite wet it will not attach itself to them at all.

Mortar joints and beds. As mortar is a more yielding material, used in brickwork merely for the purpose of making the detached portions of the staple adhere, by filling up their interstices and excluding the air, and the object is to produce as unyielding and consistent a mass as possible, no more should be used than is sufficient to produce the desired result. No two bricks should be allowed to touch, because of their inaptitude to adhere to each other; and no space between them should be left unoccupied by mortar which may produce adhesion. When the bricks are a fraction under $2\frac{1}{2}$ inches thick, four courses of bricks and mortar, or brickwork, are usually allowed 11 inches in height; and if they are fully that thickness, four courses are allowed $11\frac{1}{2}$ inches. The result of thick beds of mortar between the bricks is, that the mortar is pressed out after the joint is drawn, on the outside, in front; and being made convex instead of slightly concave, the joints catch every drop of rain that may trickle down the face of the wall, and are thus saturated; the moisture freezes, and in thawing bursts the mortar, which crumbles away, and creates the necessity, which is constantly recurring, of pointing the joints to preserve the wall. The diagram, fig. 6, shows the section of a 9-inch wall, with the joints on the side *a* as drawn, and on the side *b* as bulged, in consequence of the quantity of mortar in them yielding to the weight above. This, too, is in addition to the inconvenient settling, which is the consequence of using too much mortar in the beds. In practice, bricklayers lay the mortar on the course last finished, and spread it over the surface with the trowel, considering that it will fill the space between the bricks of that course, in addition to what they may have placed in the edges of the outside joints; but the mortar ought not to be so thin as to fall into the joints by its own weight; &c., unless they press it down, half the height of the space between the bricks remains unoccupied, and the wall is consequently hollow, incompact, and necessarily imperfect. To obviate this, it is common to have thick walls grouted in every third or fourth course; that is, mortar made liquid, and called grout, is poured on and spread over the surface of the bricks, that it may run in and fill up the joints completely. This, at the best, is but doing with grout what should be done with mortar; and filling or flushing up every course with mortar requires very little additional exertion, and is far preferable. It also assists in making the house warmer and drier, by preventing the passage of wind or damp through the joints. Grouting.

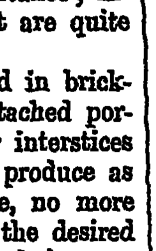


Fig. 6.

All the walls of a building that are to sustain the same floors and the same roof should be carried on simultaneously; under no circumstances should more be done in one part than can be reached from the same scaffold, until all the walls are brought up to the same height, and the ends of the part first built should be racked back, as at *a b*, Plate XX. fig. 2, and not carried up vertically with merely the toothing necessary for the bond, as at *a b*, fig. 3. Walls be carried up together.

Brickwork should never be carried on in frosty weather, nor even when it is likely that frost will occur before the walls can be covered in or become so dry as not to be affected by frost. Covering an unfinished wall with a thick layer of straw when frost may supervene is a very useful precaution; and on the straw weather-boarding should be laid, to prevent access of moisture from rain or snow. Merely wet weather may be guarded against by following the directions given above as to flushing every course of the work well up with mortar, so that no interstices be left into which water may insinuate itself, and by covering the walls with boards to act as a coping when the men are not actually at work on them; the joints in the face of a wall that is not to be plastered in any way should be protected in this manner with great care. Frost.

After the footings of a wall (above noticed) have been brought up to the level of the finished surface of the ground, or to the underside of the joists of the lowest floor, there should always be introduced a damp-proof course, intended to prevent that rise of damp from the soil in the brickwork which is the cause of so much disfigurement and injury to buildings. This damp course is formed in various ways, as a layer of asphalt, or asphalt canvas, or some similar material. One of the best and most usual, as the materials are always at hand, is formed of two courses of slates, well breaking joint, and set in cement. Another is Taylor's or Jennings's patent stoneware damp course, which being pierced horizontally admits air to the space under the floor and thus ventilates it. Damp-proof course.

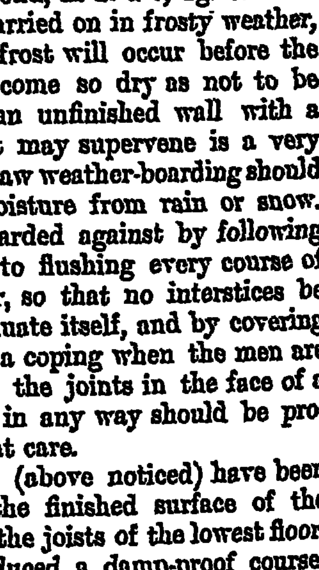

Fig. 7.

Where the ground would come against the walls of a basement story, it is requisite, in order to keep them dry, either to form an open drain or area, or to make what is called a dry area. This is done by building up against the soil a thin wall of brickwork not less than 8 inches from the main wall, and either straight or curved, and covering it over above the ground with stone or slate, as in fig. 7. Thus any water coming through the thinner wall falls down, and is conveyed away or soaks through the bottom. This thinner wall requires Dry area.

support from the main one, and the cavity has to be ventilated.

Partition walls. Besides the outer or main walls of a house, there are interior walls, or partitions as they are called. These in large structures are always executed in brickwork; in smaller ones they are usually constructed of timber; and these timbers are often filled in between the uprights by brickwork formed of bricks laid flat or on edge according to the thickness of it. A plate of wood is occasionally introduced to strengthen the work, which is then plastered over This is called a brick-nog partition. In many of the model lodging-houses in London the partition walls have been constructed a half brick in thickness in good mortar, for the whole height of the building, the floor joists being fixed against them to steady them.

Hollow walls. Another sort of wall consists of two skins of brickwork with a few inches between them; this is called a hollow wall. The two skins, either both of half a brick thick, or the outer one of one brick and the inner one of half a brick, are tied together by iron band-ties at various intervals. These when straight are sometimes found to transmit the wet blown through the outer facing to the inner one, so a bend or loop is formed in the centre of the tie, which throws off the water. This hollow space tends to make the houses both dry and warm, but it is said to form receptacles for insects, &c. An addition to such walls has been lately made by a series of these looped ties supporting a course of slates placed not quite vertical but sloping back slightly. The next course of ties is built in at such a level that it fixes the top of this first course of slate in place, and provides a starting for the next course. Thus, in the heart of the wall there is a continuous surface of slates, slightly overlapping at joists and at beds, and so placed that whatever moisture blows through the outer skin is not able to penetrate, but will trickle down the slates to the bottom of the cavity in the hollow wall. This is one of the many building patents of Mr John Taylor.

Materials and labour for rod of brickwork. A rod of brickwork will consume about 4500 bricks, though the number will be a few more or less than this, as the bricks happen to be below or above the average size, and as the joints are made thicker or thinner. The quantity of mortar, it is evident, will be affected by the latter consideration also; but in London it is generally reckoned at from ninety to a hundred striked bushels to the rod, or from four to four and a half cart-loads, each containing about one cubic yard. The labour on a rod of brickwork may be done on an average by a labourer in four days; this, however, does not include making and turning the mortar, nor scaffolding. Many things will, however, affect the time in which the work may be performed, both of the bricklayer and his labourer; the former can do one-fourth as much more, at the least, in walls which are to be plastered, as in those in which he has to keep the perpends and draw the joints, &c., and more in thick walls than in thin ones; and the capability of the latter will depend, inversely, on the rate at which the former can proceed, on the distance he may have to carry the bricks and mortar to the foot of the ladder, and mainly on the height he has to carry the materials up the ladder. In great heights, however, the materials should be hoisted.

Roof tiling. Tiling being much less in vogue than formerly, in consequence of the better appreciation of the superior qualities of slate for covering roofs, and the moderate cost at which slates are now furnished to the builder, it no longer maintains its separate artificer, but is performed, when it is required, by the bricklayer. Tiling is for the most

Plain tiles. part of two sorts—plain tiling and pantiling. Plain tiles are simple parallelograms, generally about $10\frac{1}{2}$ inches in length, 6 inches wide, and $\frac{5}{8}$ of an inch thick; and each tile has a hole pierced through it near one end, to receive the oak pin by which it is hooked to the lath. The tiles are laid in mortar and sometimes in hay, or moss, on the laths, which in England are of oak or fir, with an overlap of 6, 7, or 8 inches. The greatest overlap or smallest gauge makes the securest work, though it does not present so good an appearance externally as a longer gauge does; and it requires, moreover, a greater number of tiles and laths, thereby adding materially both to the weight and the cost. The great overlap and the mortar (or hay or moss) are both necessary to prevent the rain and snow from driving in between and under the tiles, especially when of a low pitch. Plain tiling requires the pitch of the roof to be at an angle of at least 50°, and is one of the heaviest coverings that can be used, though it is at the same time one of the warmest. The tiles, however, readily and rapidly absorb moisture, which they communicate to the laths and rafters under them, to the serious injury of both the latter; and the mortar in which they are set requires to be frequently pointed, the constant atmospheric changes to which it is exposed occasioning it to crumble and fall away in no long time. Terro-metallic tiles are made with projections at the back to catch on the laths, in lieu of pegs. Italian tiles have been made in England since about 1840, and are occasionally used. They are slightly curved, fit easily one into another, and have a horizontal indentation across the upper part to prevent the wind drifting the rain over the head of the tile. They have either wide or narrow vertical rolls. Taylor's new roofing tiles have a plane surface with slightly turned up edges at the sides, and a lump on the surface near the upper edge to prevent the upper tile slipping. The cover tile is of a similar size and form. They are recommended as half the weight of the common tiling; they are about as light as slating, and may be laid to nearly as flat a pitch. Other sorts of tiles.

Pantiles. Pantiles are parallelograms of irregular surface, straight in the direction of their length, which is $13\frac{1}{2}$ inches, but twisted in the transverse section. Measuring the whole surface across, a tile is 9 inches wide, but in a right line from point to point not more than 7, and its thickness is half an inch; a small tongue or lip is bent down at one end from its flatter convexity, on the under side, to hook it to the lath by, instead of a wooden pin through it, as in a plain tile. Pantiles are set dry or in mortar, on laths. They are not laid side by side, but overlap laterally as in fig. 8; consequently all the overlap they have longitudinally is 3 or 4 inches only, or enough to prevent rain and snow from driving up under the upper, over the end of the lower tile; and hence pantiling is but little more than half the weight of plain tiling.

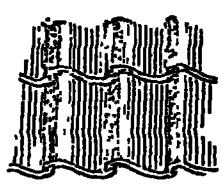

FIG. 8.—Pantiling.

It is, however, a much less warm covering for houses, and is more liable to be injured by violent gales or gusts of wind than the latter is; but again, it presents a far more pleasing appearance to the eye. Pantiling will not bear a much flatter pitch than the other. It is greatly improved by being pointed on the inside with lime and hair. Sometimes, indeed, the whole of the work is, as we have said, set in mortar; but this mode has disadvantages to which pointing internally is not liable, and its superiority in other respects is questionable. In both pan and plain tiling large concave tiles are used to cover the hips and ridges of a roof. These are not generally made to overlap each other in any situation, but are set in mortar, and fastened with nails and hooks fitted for the purpose, and driven into the woodwork of the roof. In addition to these an ornamental ridging or cresting is often introduced. A variety of patterns are now made for this purpose. Another form of

pantile very useful for common purposes is the Bridgewater tile; it is rather wider than the common tile and has a double roll, being about $16\frac{1}{2}$ inches wide and 14 inches long.

As plain tiling is heavier than slating, the plates and rafters of the roofs have to be made stouter than is necessary for slates, consequently the expense of the roofing is added to, supposing that the same thickness of wall be sufficient. The tile also imbibes one-seventh part of its weight or about 5 oz. of water in ten minutes, and takes many days to dry again thoroughly, this necessarily tending to deteriorate the timbers.

ping. When the top of a brick wall is not protected by a roof, it must be covered or coped in some manner, or it will soon be destroyed by the weather. Sometimes this is done by means of a course of bricks set across it on their edges in cement, and called a barge course, but it is a very imperfect covering, for water will trickle down the face of the wall on both sides, as the coping brick can be no longer than the thinnest wall is in thickness. Two double courses of plain tiles may be put side by side under the barge course, making a projection over each face of about $1\frac{1}{2}$ inch, as shown in *fig. 9*. This is much better than the barge

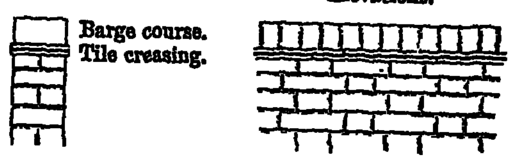

Fig. 9.—Coping.

course alone; but still the covering receives *no inclination* outwards to throw the water off; the upper surfaces are all horizontal. The same objection exists to *foot-paving* tiles, which are also used as a coping; but *none of these* methods is available for any wall above 9 inches in thickness. Stone coping, therefore, which may be made of sufficient width, and be both weathered and throated, is much to be preferred. One of the greatest faults in the modern practice of building, both architecturally as a matter of taste, and practically as a matter of prudence, is, that these copings, and cornices which serve as such, do not project sufficiently to protect the wall from the weather. A massive and well-projected cornice on a wall serves as a roof or pent-house to it; and, besides imparting great beauty to the plainest structure, protects the wall from the premature decay of its upper part especially, and of the joints generally, if it be unplastered brickwork, which thereby calls for the frequent repetition of pointing. Effective and pleasing cornices and blocking-courses may be formed with uncut bricks alone; and these, set in cement, would, with judicious management, add materially both to the appearance and durability of brickwork, without the foreign aid of either the plasterer or the mason. Figs. 10 and 11 show two of the approved modes of forming plain copings in brickwork to garden and other walls.

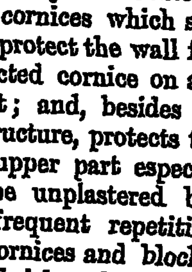

Fig. 10.

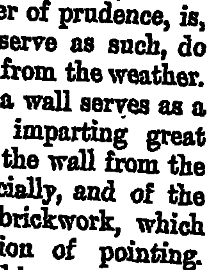

Fig. 11.

Brick Copings.

From the injury which accrues to the joints of brickwork through bad management in its execution and imperfect protection when executed, arises the necessity, so frequent at the present day, of pointing. Sometimes frost will have supervened before the surfaces of the joints in a wall are dry; consequently, the mortar bursts and peels away, and the whole then requires to be pointed. Preparatory to this operation the scaffold, if it has been struck, must be re-erected, the mortar raked out of the joints to a depth of about $\frac{3}{8}$ of an inch, or deeper if the injury have reached further;—this can be done by a labourer;—a bricklayer then goes over the whole with a hard hair brush and water to cleanse and moisten the joints; and then, with mortar prepared for the purpose, he carefully fills them all up, and neatly draws them with his trowel. This mortar must be of the best quality; it is generally compounded with a certain proportion of forge or smith's ashes, which gives it a blue tinge, and adds greatly to its power of resisting the action of the weather. Cement is sometimes used instead of this blue mortar. If peculiar neatness be required, every joint is marked with a narrow parallel ridge of a fine white putty, in the composition of which bone-lime forms a principal ingredient. The former is called flat-joint, and the latter tuck-pointing. If it be an old wall that requires pointing, a scaffold must be erected before it; and where the putlocks cannot be rested on window-sills and the like, half bricks are generally drawn from the wall to make rests for them, and restored again when the work is done. The former process is then gone through with a common wall; but if it require tuck-pointing, the whole surface is well washed, and then coloured to look like new brickwork, before the pointing is done. The gauged arches over the windows and doors are always coloured, and the joints drawn with peculiar neatness. If in the original building of the wall the perpends have not been preserved, that is, if the vertical joints have not been made to fall perpendicularly in the alternately recurring courses, the workman in pointing stops up the old joints, which are irregular, with putty of a brick colour, and forms false new ones in the proper places.

Arches in brickwork are plain, rough-cut, or gauged. Arches.
Plain arches are built of uncut bricks, and the bricks being Plain.
parallelopipeds, an arch built of them must be made out *with mortar*; that is, the difference between the outer and inner periphery of the arch requiring the parts of which an arch is made up to be wedge-formed, as in fig. 12

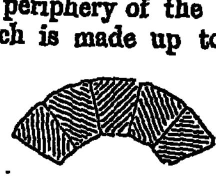

Fig. 12.

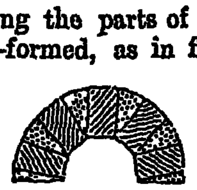

Fig. 13.

which the brick is *not*, the difference must be made in mortar, as in fig. 13, so that the inner or lower angles of bricks used for this purpose should all but touch. The mortar should be more consistent than that used in ordinary walling; and the centre on which an arch of this kind is set or built should not be struck or removed until the work is thoroughly hard, or rather all such arches should be set in cement which will harden immediately. In consequence of this inherent defect in uncut-brick arches, in extensive continuous works, such as sewers, tunnels, vaults, &c., it is advisable to make them in thin independent rings of half-brick or one-brick thick, as the case may be; that is, a 9-inch arch should be in two half-brick arches, as at *a*, fig. 6, Plate XX., and an 18-inch arch in two one-bricks, as at *b*, each arch in the latter case being bonded in itself as in a common 9-inch wall with headers and stretchers. It is evident that, by this mode of structure, a greater quantity of the solid material comes into the back or outer ring or arch than into the lower one; and if they *had* been bonded together into one arch, as at *c*, all that difference must have been made up with *mortar*. Moreover, whatever pressure comes on the outer ring is carried by it directly to the inner or lower, from whose joints, however, the mortar cannot escape or be pressed out, the *inner* angles of the bricks, by meeting, preventing it *below*, and the bricks of the upper arch, which conveys the

pressure, are themselves opposed to the back of the same joints, so that its power of resistance is made equal to that of the bricks themselves, except at the ends; which, in such works as we have supposed, are remote, and may be protected by the use of cement in their joints, whilst mortar is used in the rest. Rough arches are those in which the bricks are roughly cut with an axe to a wedge form, and are used over openings, such as doors and windows, when the work is to be plastered on the outside, or in plain back fronts, outhouses, garden-walls, &c., when, however, they are neatly pointed with what is called a tuck or tucked joint. Semicircular and elliptical arches are generally made plain, or without cutting the bricks; but arches composed of a smaller segment of a circle (vulgarly and technically called *scheme* arches), if not gauged, are cut or axed. Very flat arches are distinguished by the term camber, from the French *cambrer*, to round like an arch. It is arches of this kind which are generally employed over windows and doors in external work, and they too are either cut or gauged. Gauged arches are composed of bricks which are cut and rubbed to gauges and moulds, so as to form perfectly fitting parts, as in masonry. Gauging is equally applicable to arches and to walling, as it means no more than the bringing every brick exactly to a certain form, by cutting and rubbing, or grinding it to a certain gauge or measure, so that it will exactly fit into its place, as in the finer works of masonry. Gauged brickwork is set in a putty instead of common mortar, but it is seldom used except for arches in the fronts of houses, &c., which are to be neatly finished. These are for the most part straight, and are generally from 11 to 12 inches in depth, or the height of four courses of brickwork. Their value as arches will be best understood by reference to the diagram, fig. 7, Plate XX., by which it appears that all the material between the soffit of the straight arch or head of the opening *b c*, and the dotted line *b f c*, is useless, the intrados or soffit of the really efficient part of the arch being at that dotted line itself. This is the arc of an angle of 60°,—its chord, the width of the opening, being the base of an equilateral triangle constructed on it, and the joints are the radii of a circle whose centre is at *a*. *b d* and *c e*, the continuations of the sides of the triangle or radii *a b* and *a c*, are technically termed the skew-back of the arch. Sometimes the arc is made under a more acute angle, in which case the skew-back is less, that is, the external angles *c b d* and *b c e* are less obtuse; a smaller unavailable portion of the arch is thus left between the arc and its chord, but that portion is less securely retained under the flatter segment, because the joints or radii diverge less, or are more nearly parallel. These gauged arches being, as they for the most part are, but a half brick in thickness, and not being tied by a bond to anything behind them—for, indeed, almost the whole, if not the whole, of their height is occupied behind by the reveal and the wooden lintel—require to be executed with great care and nicety. It is a common fault with workmen to rub the bricks thinner behind than before, to insure a very fine joint in front. This tends to make the work bow outwards; it should rather be inverted, if it be done at all, though the best work is that in which the bricks are gauged to exactly the same thickness throughout. The same fault occurs when a gauged arch is inserted in an old wall, on account of the difficulty of filling up with cement the space behind the bricks. Fig. 8, Plate XX. is a transverse section of fig. 7, and the gauged arch, lintel, &c., in it show the total disconnection of the gauged arch with any surrounding brickwork to which it might be bonded. The absurdity of constructing arches circular on plan, especially in a thin unbonded shell of bricks, is so clear as hardly to require notice.

Plates and wood-bricks.

It is generally held that nothing but its own components should be admitted into a brick wall, except what is absolutely necessary for its connection with the other parts of a building, such as wall-plates and wood-bricks (and that these should be avoided as much as possible), templets, lintels, &c. Wall-plates are applied to receive the ends of the joists, and distribute the weight of the floor to which they belong equably along the walls. If the joists tailed singly on the naked bricks, their thin edges would crush those immediately under them, and the rest of the brickwork would escape immediate pressure altogether. Wall-plates may be avoided by the use of framed floors, which are carried by a few large beams, under whose ends stout pieces of timber or stone, 2 or 3 feet in length, are placed. These supports are intended, like a wall-plate, to distribute the weight over a considerable part of the wall, and prevent the necessity of placing the beam on the naked friable bricks, and are called templates. As bond timbers and wood-plates are now interdicted by the Buildings Act in London, the joists have to be tenoned into trimming joists carried by brick, stone, or iron corbels.

Lintels.

Lintels are used over square-headed windows and doors, instead of arches in brickwork. They are useful to preserve the square form and receive the joiner's fittings, but they should always have discharging arches over them, and should not tail into the wall at either end more than a few inches, that the discharging arch be not wider than is absolutely necessary. Fig. 9, Plate XX., indicates the elevation of the inside of part of an external wall with a window in it, and shows the lintel over the opening with a discharging arch over it, and wood-bricks under its ends, on the jambs of the opening. Discharging arches should be turned over the ends of beams, and templets also, as in fig. 10. They may generally be quadrants of a circle or even flatter, and should be turned in two or more half bricks over doors and windows, and other wide openings, but over the ends of beams they need not be in more than one half brick.

Discharging arches over openings.

Wood-bricks.

Wood-bricks are used to prevent the necessity of driving wedges into the joints of brickwork to nail the joiner's work to. They are pieces of timber generally cut to the size and shape of a brick, or portion of one, and worked in as bricks in the inner face of a wall, where it is known the joiners have occasion for something of the kind. This is principally in the jambs of the windows and doors for their fittings, and along the walls, at proper heights, for the skirtings or wainscotting, as the case may be. The use of bond timbers in brick walls is objectionable because of their liability to shrink and swell, to decay, and to be set on fire; and in England the use of timber in walls has, since the extension of the manufacture of iron in these countries, been in a great degree superseded by that metal in the form known as hoop iron.

Bond timber.

Hoop iron.

Thin and narrow strips of this metal are laid in the bed joints of mortar, at intervals more or less frequent according to the nature and character of the work, with the best effect in respect of compactness and consequent strength. An improvement on the straight band has been introduced by Mr Tyerman, whereby a notch is made and the tongue bent down, which coming at each hollow of the bricks tends to afford a better hold on the mortar.

Brick and ashlar work.

It will be generally found that a brick wall built with mortar and faced with ashlar has settled inward to a less or greater extent, as the work has been more or less carefully performed. Indeed, in the nature of things it cannot be otherwise, unless the brick backing be worked in some cement which sets and hardens at once; for the outer face is composed of a layer of unyielding material, with few and very thin joints, which perhaps do not occupy a fiftieth part of its height, while the back is built up of an infinity of small parts, with fully one-eighth its height

of joints, which are composed of material that must both yield to pressure and shrink in drying. Some part of the ill effect attendant on this is obviated by the bond-stones, which tail in or run through the wall, and tend to keep the discordant materials together; but still much of it remains. And besides this, the internal or cross walls, which have no stone in them, will either settle down and shrink away from the external walls, or drag them inward, as they happen to be well or ill bonded or tied. For these reasons, brickwork built in this manner with masonry should be executed with exceedingly well-tempered mortar, made with no more lime than is absolutely necessary to cement the particles of sand together, and the sand again to the bricks, worked as stiff as it can be, and laid in as thin courses as may be to answer the purpose required of it. Above all, work of this kind must not be hurried, but allowed time to dry and shrink as it goes on. In some large edifices the brickwork is carried up and completed, and after a sufficient time has elapsed for the work to have settled, the ashlaring is carried up and worked in with the bond stones set in the brickwork for the purpose.

Discharging arches under openings.

Discharging arches over vacuities having been disposed of incidentally, we have now only to speak of them under openings, in which situation their use is to distribute the superincumbent weight equally over the substructure, or along the foundation as the case may be. For this purpose the arch is inverted, as shown in fig. 4, Plate XXI.; and by means of it the weight brought down by the piers is carried along the footings, which are thus equally borne upon throughout their whole length. Arches of two half bricks are indicated here, that being sufficient for ordinary purposes, and to develop the principle; in large and heavy works, arches of three half bricks, and even greater may be judged necessary. Any arc between a quadrant and a semicircle may be used with advantage; but an arc of less than 45° cannot be recommended for the inverted discharging arch under piers. Arches require abutments whether they are erect or inverted; this is often forgotten when inverted arches are used.

Chimneys and flues.

Not the least important part of the bricklayer's art is the formation of chimney and other flues. Great tact is required in gathering-over properly above the fire-place, so as to conduct the smoke into the smaller flue, which itself requires to be built with great care and precision, that it be not of various capacity in different parts, in one place contracted to a narrow straight, and in another more widely expanded, and so on. There is now often introduced at the level of the mantel, a plate with an opening in it through which the smoke ascends. This, which is called a chimney-hopper or chimney lintel, is very useful not only to ensure the proper gathering of the flue, as the brickwork of the flue is formed at once upon it, but as a substitute for the usual register, and it also renders needless the usual iron chimney bar required to support the breast. It is absolutely necessary that flues be of a certain magnitude, but the bore should be regulated by the size of the fire-place, or rather by the quantity of smoke to which it is required to give vent. For large kitchen fires it is considered best to have two flues.

Chimney hopper.

Practical men differ as to whether a tapering flue, or an enlarging flue is best for carrying away smoke. They are usually made of one size throughout. Of late years cylindrical earthenware tubes have been used with advantage, and of a smaller bore than the common 9-inch by 14-inch capacity. With glazed tubes it has been found that the soot falls down with thunderclaps and other strong vibrations. Flues of brick are plastered or pargetted with a mortar in which a certain proportion of cow-dung is mixed, which prevents it from cracking and peeling off with the heat to which it is exposed. The part brought out into the room from the wall, and over the opening, is called the breast. The flooring in the opening is called the hearth, fig. 8, Plate XXI.; it is set on the bricks or stones of the wall, and is usually of stone, although cement and iron plate are sometimes used. The slab is that part of the floor of a room which is immediately before the fire-place, and along the extent of its front. In basement rooms, this slab is supported by a brick wall brought up from the ground; but in upper rooms the slab is supported by a flat half brick arch called a brick trimmer, which is turned from the chimney breast under the hearth on one side to the trimmer joist on the other, which is generally made somewhat thicker than the other joists for this purpose. The chimney-piece which comes in front is fixed by the mason after the carpenter's work is done.

Causes of smoky chimneys.

The plate above mentioned assists in ensuring a proper draught to the flue, and preventing a smoky chimney. These are frequently caused by want of sufficient air to feed the fire, which must be supplied from the room itself or by a tube brought from the outside of the building. Another cause of smoke is too short a funnel, especially if the flue be a large one, as formerly built for sweeping by boys. Every fire-place must have its own flue. Other causes are—one fire overpowering the other, when there are two in one large room, or two rooms communicating by a doorway, or when the tops of chimneys are commanded by higher buildings, or by a hill, so that the wind sometimes blows almost perpendicularly into the tops of the chimneys that lie in its way and beats down the smoke. A down-draught is usually produced by the difference of the external atmosphere from that in the room; this often brings down the smoke of a neighbouring chimney; it can occasionally be obviated by raising one of them, or by fixing on it one of the exhausting pots now manufactured for the purpose. The bad construction of fire-places is another cause of smoky chimneys, the throat being too large for the fire. We shall not attempt to describe the many patent and other inventions submitted for curing these nuisances, but what is known as Billings's terminal must be excepted. It consists of a low conical top about a foot high, placed on the flue, and screened on each side by a terra-cotta baffler, rising somewhat higher than the pot; the wind striking the former is thrown upwards and assists in extracting the smoke; the latter prevents the smoke of one flue being blown down the adjoining ones in the same stack. The common terra-cotta pot with louvre sides is also useful and ornamental.

Paving, brick.

Brick and tile paving is performed by the bricklayer. Brick-paving is either flat or on edge, in sand or in mortar or cement. Brick flat-paving in sand, that is, with the bricks laid on their broadest surfaces, and bedded in and on dry sand, is very slight and fragile, and brick flat-paving set and bedded in mortar is very little better; for if the soil on which the paving is laid be light and sandy, the bricks are easily displaced by being pressed unequally; and if it be clayey it will probably be moist, and the thin porous brick absorbing the moisture, will generally become saturated, and present a damp unwholesome floor. Paving with bricks on their edges, however, forms a much better floor, and is preferable to a stone paving, if the latter be laid on the ground without the intervention of footings. Brick-on-edge paving in sand is generally used in beer cellars, pantries, dairies, stables, &c., as its numerous open joints allow wasted or discharged fluids readily to escape; and it is both cool and dry under ordinary circumstances. In mortar or cement, bricks on their edges form a sound, dry floor; the smallness of the surface exposed by each brick in this manner leaves them, of course, less susceptible of partial pressures, and the depth from the soil to the

surface is such that damp rarely shows through. The paving brick differs from the common brick only in thickness, its dimension in that direction being rather less than 2 inches, instead of $2\frac{1}{2}$ inches, and in being rather harder and more compact.

FIG. 14.—Paving of Dutch Clinkers.

ch cers. Dutch clinkers are paving bricks, smaller and much harder than the English, and of a light yellow colour; they are 6 inches long, 3 inches wide, and $1\frac{1}{2}$ inch thick, and are always set on edge and herring-boned, that is, instead of being placed in parallel lines, they are set at right angles to each other, as in fig. 14, yet with a perfectly even face. ing in Paving tiles are made $9\frac{1}{2}$ inches and $11\frac{1}{2}$ inches square, though they are called 10-inch and 12-inch or foot tiles respectively, the former being 1 inch, and the latter $1\frac{1}{2}$ inch thick; they are set in courses, as stone paving would be, the alternating courses breaking joint. A sort of tiles called terro-metallic are manufactured for stabling and similar purposes.

amen- nd r tiles. Here may be mentioned the extended manufacture of ornamental tiles. The tiles formed in intaglio and enamelled, similar to those used by the Moors in Spain, have enabled the architect to break through the monotonous surface of brick buildings, and to introduce ornamental forms and colour without the necessity of resorting to plaster and stucco. From the geological position of London and many other towns, bricks must always be the prevailing material for building purposes; such means, therefore, for the safe introduction of colour and ornament are especially desirable and should be carefully studied. With this, too, has come the extended use of ornamental brickwork by the introduction of moulded bricks of all forms, and of many colours, together with a material of a like nature, by which decorative work of a more ornamental character can be obtained, namely terra-cotta, or prepared clay moulded or wrought and then burnt in a kiln. Tiles as above referred to are made for mosaic and tesselated pavements in plain colours (some being enamelled), for halls, footways of landings, conservatories, &c., also glazed tiles for hearths, and white and toned tiles, with the encaustic tiles of many colours, for walls. The former are manufactured of all sizes, so that by the combination of certain forms and colours an endless variety of patterns are obtainable. For pavements they require to be carefully set in cement on concrete, and in cement on walls.

ers and ins. Sewers and drains which are not cylindrical should be built with concave bottoms; this keeps the stream more together, and enables it the better to carry its impurities along with it, whereas a flat-bottomed drain offers a large surface for the particles of soil to attach themselves to, and the stream of water being more scattered is less efficient in force. Drains near houses, and in other places where it may be necessary to open them at any time, may be of the form of which *a*, fig. 1, Plate XXI. is a section, with a flat covering of stone paving, or large paving tiles, set and jointed with cement. Gun-barrel drains, of 9-inch or 12-inch diameter, as at *b*, are the best in exposed situations, because they are the strongest; but as there is no mode of cleaning, if they are too long to be raked, but by breaking them up, they should not be employed except with a considerable fall and a frequent or constant stream of water through them, as from a pump trough, rain-water trunks, &c. They are constructed on a barrelled centre of wood, which the bricklayer drags on as he advances with his work, finishing as he goes. No drain should have an inclination or fall of less than one-quarter of an inch to a foot; and where the stream is infrequent and dull, as much more would be a great advantage. Large sewers, urs. which are accessible from the ends, or from side entrances, for men to clear or remove any accidental obstructions, are best made circular, elliptical, or egg-shaped, as in fig. 15 The last two shapes are generally preferred, because in proportion to the capacity the height is greater. The form in fig. 15 maintains the greatest possible depth with a small quantity of fluid, and combines this qualification with those of great strength to resist external pressure and large capacity with a given amount of materials. The form shown at *c*, fig. 1, Plate XXI., is now disused, though it was long advocated for sound workmanship and regular joints. A rate of fall of 1 in 120, or 1 inch in 10 feet, is desirable, although less will suffice for a main sewer.

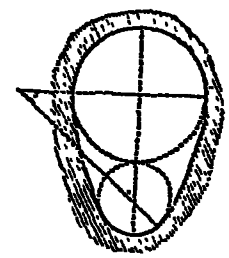

FIG. 15.—Section of Sewer.

Pipes or hollow cylinders of well-made and well-burnt glazed stoneware form the most efficient house-drains. Pipe drains. Such pipes are put together with great accuracy with sockets, so as to fit spigot and faucet fashion; movable tops are provided so as to give access to them at any part required, without taking up and relaying the drain from one or other of its ends, as was so often the case with the old brick drain. Proper bends, junctions, syphons, &c., are also made of the same material. In using pipes for drains, it should be borne in mind that a little larger than large enough is better than the reverse of this. No pipes should be laid down for a house-drain of less bore than 6 inches, nor should earthenware be used for drains requiring a greater bore than 12 inches; the material is too weak to allow of more, and the material is not strong enough to stand more than a dead pressure. Glazed stoneware pipes are also employed for small sewers in side streets, or to take off the collected soil and water from a short row of houses into the main brick sewer, and thence to a watercourse or to a reservoir of a main drainage scheme.

In building drains it is of great importance that proper Trap traps should be constructed to prevent the ascent of foul air and the passage of vermin. At every sink there should be a bell-trap, and a well-trap within that, or near the hither end of the drain. Suppose a drain leading from a kitchen or scullery to the common drain of the house, in which it meets that which may come from the water-closet and other places. The bell-trap in the sink itself will prevent the return of smell when it is constantly in use, but it is liable to be left out, broken, or otherwise injured, or it may become dry by evaporation; it is, therefore, necessary to have a trap not so liable to such ordinary contingencies. Let a well be made 18 inches or 2 feet in diameter, square or round, and 2 feet 6 inches or 3 feet deep, across and below the level of the drain, as shown in plan, fig. 2, Plate XXI., and in longitudinal section, fig. 3; it must be built around with brick in cement, and be plastered on the inside with the same material, which will make it capable of retaining fluids. Uprightly across this well, and in the transverse direction of the drain, must be placed a sound piece of paving stone, so long that its ends may be inserted in the sides of the well, as shown in fig. 12, and so wide that its upper edge shall touch the covering of the drain, and that its lower may reach 6 or 9 inches down into the well below the bottom of the drain. Mortar or cement must prevent the passage of air between the upper edge of this trap-stone and the cover of the well and drain, and the trap is complete. The water coming from the sink flows along the drain from *a* to *b* (fig. 3), where it falls into the well, and filling it up to that level it flows on again from *c* in the direction of *d*, to the cess-pool or common sewer from which, however, no smell can return; for the trap-stone

e, the lower half of which is thus immersed in water, completely bars the passage. It is evident, however, that if the well should leak the water in it may fall below the lower edge of the stone, and the efficiency of the trap be destroyed; but if it be made perfect in the first instance, there can be no danger of any inconvenience that a bucket of water thrown into the sink will not cure. It is from the drying up of the fluid in water-traps that uninhabited houses are so frequently offensive. These well-traps form an effectual bar to vermin, and they may, therefore, be advantageously placed at the entrance of water-closet drains, to prevent rats from getting at the soil-pipes, which they will gnaw and destroy if they can get access to them. Internal drains, or those which go through a house, should always pass under the doorways if possible, in external walls at least. If, however, circumstances should render it absolutely necessary that a drain be taken through a wall, an arched ring or bull's eye should be made for it to pass by

Ventilation. All the traps to the drains should be ventilated, as well as the head of the drain itself, by a tube carried up to the top of the house, and away from any opening where the foul air could be blown into any of the rooms. The sewers should also be ventilated, if not by the gully or side gratings, then by a grating placed over them in the centre of the roadway There have been numerous suggestions for ventilating shafts in the lines of main drainage, but nothing beyond a tall lamp-post has been carried out, and no doubt this is sufficient.

Cesspools and tanks. In country houses where the drainage is used for manure to the gardens or land, the drain from the closets may be led into a brick or iron tank or cesspool, the surplus water being carried off by an overflow drain. Cesspools are strongest if made cylindrical, and should be bricked round and domed at the top, with a manhole in it for access, which should be fitted with a stone, having a ring in it by which the stone can be raised. But whether they are made to retain fluids or not is not a matter of consequence, if they be placed in a secluded situation, where, if the object be not to get rid of the waste, there is seldom, at least, any desire to retain it. In towns and cities where the common sewering is as complete as it ought to be, and water-closets are used insteaa of privies, cesspools are unnecessary, as the soil becomes so much diluted by the water that goes down with it, that it flows readily enough through the private drains to the common sewer, and so on with the rest, to the common receptacle. Sometimes, indeed, it may be found necessary to clean out the well-traps before described, but this cannot often occur. Galvanized tanks are occasionally used in some parts of the country, with pumps attached, by which the sewage can be rendered available for the garden. Earth closets on Dr Moule's system, or the cinder-sifting ash closets, are valuable for preventing the waste of an important manure. For workmen's cottages in large towns and villages they must be of great service, but whether they are adapted to a town house, or are applicable on an extensive scale for the relief of town drainage, is a question which still remains unsolved.

Earth closets

Mason-Work.

The word *mason* is derived directly from the French *maçon*, which signifies indifferently a bricklayer or mason. Du Cange attributes the origin of the word to the low Latin *maceria*, a wall; but a more probable derivation is that from the old German *meizan*, to cut. Among ourselves, at present, we reckon three sorts of artificers—rubble or rag-stone masons, freestone masons, and marble masons. This last branch, however, is rather that of the carver or statuary. The art of working or reducing stone to the proper shape for the mason to *set*, *i.e.*, to place them in the walls, &c., has generally been called *stone-cutting*, and depends very much on the nature of the stone for its details. *Stone masonry* is the art of building in stone.

The mason's tools consist of a handsaw, for cutting soft stones; a drag, which is a flat piece of iron wherewith to finish its surface; chisels and gouges for forming mouldings, gauges and moulds for sinking them to the proper forms; a mallet, chisels, tools, and points for working the harder stones; a level, a plumb-rule, a square, a bevel, with rules of various sorts wherewith to try the surfaces in the progressive stages of the work. Granite is brought to a face by the scabbling hammer or granite axe, and the operation is called nidging. In rubbed work a surface is obtained by smoothing it with sand or gritstone. Marbles are polished by being rubbed with the gritstone, then with pumice-stone, and lastly with emery powder. Tools.

Rubble walls are scaffolded with single, and ashlar-fronted or other gauged stone walls with double-fronted scaffolding,—the former tailing one end of the putlocks in the wall, and the other having an inner row of standard poles, and ledgers parallel to the outer, making the scaffold entirely independent of the wall. In some places, however, it is the custom to dispense altogether with an external scaffold in building stone walls, particularly with gauged stones. With light and plain work this may be done without much inconvenience or retardation; but if the work be heavy or delicate, considerable delay and incorrectness result. Sometimes the finer work, such as that to mouldings, flutes, and foliate or other enrichments, is merely boasted or roughed out before the stones are set, and finished afterwards, but this can be done well only from a secure floor or scaffold on which the workman may feel he can move freely and surely. For large and elaborately decorated structures, such as a public building, a mechanical scaffolding has to be erected, by which some economy is effected through diminishing labour, or some emergencies met attendant on the works themselves. Where the face of a stone is worked in the shop and may have some weeks or months labour on it, it becomes a valuable work worth careful handling. Hence the old-fashioned kind of scaffolding, of poles and ropes, has been much superseded by the so-called whole timber or framed scaffold, with its tramway and crab engines aloft. It is usually formed by laying square timbers on the ground to receive similar uprights, which are secured by iron ties to it; on the heads of these are placed horizontal timbers, which are also secured to the uprights, and the whole is kept from changing position by timber struts and braces. On these another range may be erected, and so on to the required height. Tramways are placed on it, and a travelling crane, worked by hand labour or by steam, raises the heavy weights, carries them to their places, and at once deposits them in the work with great ease. By the use of a steam-lift, with a long arm to reach many feet above it, on the first stage of the frame scaffold, no other scaffold is necessary except a slight one for the use of the workmen to set the stone. The clock tower at the Houses of Parliament was built by a scaffold formed of two timbers, Scaffolding.

each 2 feet 3 inches deep and 14 inches wide, running across from side to side, on which rails were fixed to carry a travelling platform of the whole width which went the reverse way. To one side of the first named timbers was suspended a platform which carried the machinery for raising the materials from the bottom up the central shaft; they were then raised on to the traveller which carried them at once to the required spot for fixing. When a certain height of work had been done, the huge timbers were raised by six screw-jacks working together, and rested on the new wall, the jacks being removed and prepared for another raising when necessary. The Victoria Tower was erected on a somewhat similar principle, but having two travellers working upon a circular tramway on a strong trussed framing, the ends of each secured to a central drum. To raise the materials a strong under-trussed parallel framing was formed on one side, which brought them up on the outside of the tower.

Stones used in Building.—It may be useful to give a list of the stones principally used in building, according to their geological formation, with some practical remarks upon each.

Of *igneous rocks* of *volcanic* origin, the varieties which are used on the continent of Europe are those light stones called tufa and pumice, and the stone called peperino. The two former were extensively employed by the Romans in the filling in of vaulting, on account of their great lightness. The latter stone, which is obtained in large quantities near Rome, was used by that people extensively, particularly for substructures, being obtained in large blocks. Of the second division of igneous rocks, the *trappean*, porphyry and serpentine have been used, but chiefly as ornamental coloured stones, and have been generally classed as marbles. Of the third division, the *supersilicated* rocks, granite alone is now extensively employed, not only in engineering works, but in public buildings and dwellings. It is got from the quarries by splitting the blocks with wedges, and is so hard that it cannot be cut by any ordinary saws. It has to be worked first with large hammers, and then reduced by pointed chisels, and consequently is very expensive in building. Machinery is used very largely in cutting and also in polishing it. Some very good specimens come from Cornwall and Devonshire, but by far the best are from Dundee and Aberdeen. A variety of the latter, called Peterhead granite, is only to be equalled by the finest Oriental granites. The Kingstown granite from near Dublin is much used locally.

Of *the aqueous rocks, mechanically formed*, and of the *arenaceous* varieties, gravel is used for concrete, and sand in making mortar. Sandstones and gritstones are very extensively used. These are either laminated, as the York stone, used generally for paving, as it can readily be split into large surfaces of small relative thickness, or compact, as Old Red Sandstones, which stand very well internally, but perish sadly with the weather, as may be seen at Chester Cathedral. The New Sandstones, the best of which is the Calverley stone got near Tunbridge Wells, are easily quarried, but if sawn, the wet saw and sand must be used. The finer grained compact sandstones, which are comparatively free from iron, and form very good building-stones, are very numerous. Such are the Bramley Fall, used for bridge copings, plinths, &c.; the Park Spring, Elland Edge, Whitby, and others, all in Yorkshire; the Hollington in Staffordshire; the Mansfield in Nottinghamshire; and the Minera quarries at Wrexham. A bed of the last is much used at Chester and Liverpool for building purposes, and it has just been introduced into the London market, for which city it is thought it will be very eligible, on account of its lasting qualities; it has been also used at the National Safe Deposit Company's offices in London. Scotland can boast of some of the finest quarries of sandstone, the best, perhaps, being the Craigleith, much used at Edinburgh. The College, courts of law, Register House, Custom-house, Royal Exchange, National Monument, and many churches and private residences there, are built of this excellent material, which has also been extensively exported to Hamburg, Altona, Gothenburg, and other places. Humbie stone has also been much used, both at Edinburgh and at Glasgow, where it forms the Royal Exchange and Royal Bank; it is easier to work than Craigleith. Glamis is also a fine sandstone; the castle there, as well as those at Inverquharity and Cortachy, and Lindertis House, are built of this material. In Fifeshire, at Cullalo, are quarries whence the stones for the monument to Lord Melville at Edinburgh, and that to Lord Nelson at Yarmouth, were obtained. In addition to beauty and durability, these stones have the merit of being capable of receiving the finest and smoothest forms from the chisel of the workman. Another class of sandstones are commonly called *firestones*, as they endure the action of fire better than most others. Of these the best known is the Reigate stone, which is the principal material used at Windsor Castle, Hampton Court, and in many old buildings round London. The Minera stone already mentioned is another.

Of *mechanically-formed aqueous stones* classed as *argillaceous*, the Clunch only is used in building. It may be seen in Ely and Peterborough cathedrals, and many other mediæval buildings, and is a beautiful material for interior carved work, but will not stand the weather.

Of the *aqueous stones* classed as *chemically formed*, there is none of note but the Travertine, or, properly speaking, Tiburtine. This is a coarse grained stone, of warm colour, found in large blocks, and extensively used at Rome, both in ancient and modern buildings, of which the cathedral of St Peter's may be cited as an instance, but it is unknown in England.

Of *aqueous rocks, organically derived*, the *calcareous* claim principal attention. The chief of these are the *limestones*, which are classed as compact, magnesian, or oolitic limestones. Of the first, the best, in the south of England, is that called Chilmark, of which Salisbury Cathedral and Wilton Abbey, and many other fine buildings, have been erected. In the Midland counties the Tottenhoe stone, of which Dunstable Priory, Woburn Abbey, Luton church, &c., are built, is an excellent stone. There is also a stone of high quality got at Hopton Wood, near Worksworth in Derbyshire, used at Chatsworth, Belvoir, Drayton Manor, &c. Ancaster stone, near Sleaford in Lincolnshire, has been used for a number of years; also Ham Hill, near Yeovil, in Somersetshire. Of magnesian limestones we may name the Anston and Bolsover Moor stones, used formerly at Southwell Minster, and lately at the Houses of Parliament; the Tadcaster stones, used at York, Beverley, and Ripon Minsters, and very many other buildings; the Roche Abbey, used at the building of that name, and very many other churches in Yorkshire and Lincolnshire; the Brodsworth, near Doncaster; and the Huddlestone, near Sherburne in Yorkshire. These stones contain a great deal of carbonate of magnesia, from which they take their name, are of beautiful texture, and stand well in the country as building stones, but fail in London.

A very excellent limestone for rough walling, especially for Gothic work, is that called Kentish Rag. It is found in large quantities in the neighbourhood of Maidstone; it is very hard, and is worked with large hammers instead of the saw. Jambs, strings, and mouldings are sometimes worked of it, but the hardness makes the work expensive; these, as well as the quoin stones and dressings, are therefore formed of Caen or Bath or other local stones. Kentish Rag does not answer for interior work.

The most important subdivision of the limestones used in masonry is the *Oolitic*. They are so called because they resemble, when broken, a conglomerate of globular eggs; they are also named roe-stones, from their resemblance to what is called the hard roe of a fish. Very good examples of these are the Barnack stone from Northamptonshire, of which Peterborough Cathedral, Croyland Abbey, Burleigh House, &c., are erected, and the Ketton stone, used at most of the colleges in Cambridge, and at Bury St Edmunds, Bedford, Stamford, Doulting in Somersetshire, and at Wells Cathedral and surrounding churches. But the principal English oolites used in masonry are the Bath and the Portland. The former, as its name imports, is found in the neighbourhood of Bath. The chief quarries are the Box Hill, Combe Down, Farleigh Down, and Corsham Down; all these quarries vary in quality at different depths. The Corsham Down is said to produce the finest in quality, and the Box Ground stone to be the hardest; but everything in the use of this stone depends on the bed selected. Large quantities of a similar stone are imported from Caen, in Normandy. This is more compact in texture than Bath, and therefore fitter for carving, but does not appear to stand our climate so well. The best variety of this stone is said to be the D'Aubigny stone. Almost all these oolites can be sawn with a common dry saw, which saves a great deal in the labour of conversion. But, without doubt, the best of all this class of stones is that from the Island of Portland; for beauty of texture, and for durability, it perhaps exceeds any stone in the world. It seems the only one unaffected by the smoke of London; and therefore the greater number of its buildings, St Paul's among the rest, are of this stone. Being of hard texture, however, it must be sawn by the use of sand and water, and is much more expensive to work than the softer oolites. There are between fifty and sixty quarries on the island. The best are said to be those on the north-eastern side; but, as with all stones, there is good and bad in every quarry, and everything depends on the selection. It is said that when Sir Christopher Wren built St Paul's Cathedral, he had this stone quarried and exposed to the weather on the sea-beach for three years, before he suffered it to be used.

Of *siliceous* stones, flint is sometimes used for rough walling and for ornamental facing with brickwork; but in England this work is done by the bricklayer, and not the mason.

The only remaining class is that of the *metamorphic rocks*, of which the crystalline or saccharine and the serpentinous limestone are used; but these are all species of marbles, used more as ornamental than as constructive building-stones, and need not be dwelt upon here.

Many of the early buildings of the Middle Ages were entirely constructed of masses of concrete, often faced with a species of rough cast. The early masonry seems to have been for the most part worked with the axe and not with the chisel. A very excellent example of the contrast between the earlier and later Norman masonry may be seen in the choir of Canterbury Cathedral. In those times the groining was frequently filled in with a light tufa stone, said by some to have been brought from Italy, but more probably from the Rhine. The Normans imported a great quantity of stone from Caen, it being easily worked, and particularly fit for carving. The freestones of England were also much used; and in the first Pointed period, Purbeck and Bethersden marbles were employed for column shafts, &c. The methods of working and setting stone were much the same as at present, except that, as the roads were then in a very bad state, and in many places the only means of conveyance was by pack-horses, the stones were used in much smaller sizes. The methods of setting out work were, however, different from those of other styles, as might be expected from the difference of forms. As time went on the art of masonry advanced till, in England, in point of execution it at length rivalled that of any country.

From the regular and determined form of bricks, modes or systems for setting or arranging them may be formed, and any workman, by habit and an exertion of memory merely, may become competent to build a brick wall as well as it can be built, but it is not so with stone used in common masonry walling. The workman in this material has for the most part to deal with masses of all forms and of all sizes, and a continual exercise of the judgment is required from him beyond the tact or skill which may be acquired by practice. For this reason workmen are generally less to be trusted to their own discretion in stone building than even in bricklaying. The young mason should be extremely careful to avoid making the beds of stones concave or hollow; for if this be done, in any case where the stones have to bear much pressure, they will flush or break off at the joints and disfigure the work. The best or highest sort of stone walling is the easiest to set; it is that in which the stones are all tooled and gauged in regular parallelogramic figures, to range in courses and suit the thickness of the wall to which they are to belong; and the most difficult to execute properly is that in which amorphous stones are used, the mason being allowed merely to dress them roughly with his hammer or axe, and fit them in as he best can to form the most compact mass: this is called rubble walling.

From the brittle nature of stone, great tact is required in setting, to prop or bear up the longer pieces in every part, or they will break across, and thus occasion more injury than could accrue if the whole mass had been made up of small pieces. Very long lengths, therefore, should be avoided, even in regular tooled courses, with which the bearing is or should be perfectly even, and a settling down of the work itself is hardly to be feared. There is a certain medium which may be preserved; and although the object is obviously, in stone as in brick walls, to form a compact mass, as unbroken into parts as possible, a mason will act judiciously in breaking a very long stone into two or more shorter ones, and working them in that state, though he thus makes two or more additional joints, well knowing that he has the power of counteracting to a certain extent the ill effect of joints made by himself, but that those made by accident are irremediable.

The observations made in the section on brickwork, on the use of mortar, will apply here also. Of whatever quality the stone may be of which a wall is to be built, it should consist as much of stone and as little of mortar as possible. If the stone be inferior in durability and power of resisting the action of the atmosphere to the mortar, besides the certain fact that the mortar will yield until it has set hard, and so far act injuriously, no ulterior good is gained; and if the stone be the more durable material, the more of it that enters into the wall the better. Indeed, in rough walling, if the stones be pressed together until the more prominent angles on their faces come into actual contact, the interstices being occupied by mortar, it will be better than if a thick yielding mass were allowed to remain between them. Absolute contact, however, should not be permitted, any more than in brickwork, lest the shrinking of the mortar in drying leave the stones to such unequal bearing as the prominent parts alone would afford. Stone being generally of a less absorbent nature than brick, it is not a matter of so much importance that it be wetted before setting; nevertheless, adhesion on the part of the mortar is more certain and more complete, if the stones be worked in at least a damp state.

What bond is, and the necessity for it, have also been shown in the preceding section; and bond is of not less importance in stone walling than in bricklaying. We have also hinted above at the greater difficulty of understanding, forming, and preserving it in the former, and can now only add a few observations in addition that can be of any use, and these with reference to rubble walling particularly. Instead of carefully making the joints recur one over the other in alternate courses, as with bricks and gauged stones, the joints should as carefully be made to lock, so as to give the strength of two or three courses or layers between a joint in one course and one that may occur vertically over it in another. In bonding through a wall, or transversely, it is much better that many stones should reach two-thirds across alternately from the opposite sides than that there should be a few thorough stones, or stones extending the whole thickness of the wall. Indeed, one of the many faults of stone masons is that of making a wall consist of two scales or thin sides, with thorough stones now and then laid across to bind them together, the core being made up of mortar and small rubble merely. This is a mode of structure that should be carefully guarded against. There is no better test of a workman's tact and judgment in rubble walling than the building of a dry wall, or wall without mortar, affords. Walls are frequently built with mortar that without it would have fallen down under their own weight in a height of 6 feet, in consequence of their defective construction,—thus rendering it evident that they are only held together by the tenacity of the mortar, which is very seldom an equivalent for a proper bond of stone. Masons are very apt to set thin broad stones on their narrow edges to show a good face, by which the wall is injured in two ways; the practice tends to the formation of a mere case on the surface of a wall, and it for the most part exposes the bed of the stone to the atmosphere, as a stone is more likely to be broad in the direction of its bed than across it.

The footings of stone walls ought to consist of the largest stones which can be conveniently procured. It is better to have them of a rectangular form than any other; and if they are not square, their largest surfaces should be laid horizontally. With this shape and disposition they will make the greatest resistance to sinking. When footings can be obtained the full breadth of the wall in one piece, they are to be preferred; but if not, then every alternate stone in the course may be the whole breadth. Each course should be well bedded in mortar.

Rubble walling is either coursed or uncoursed. In the latter sort, fig. 5, Plate XXI., the work is carried on with stones of any sizes, as they occur, and without reference to their heights, somewhat in the manner of the Cyclopean walling of antiquity,—the interstices of the larger being filled up with smaller stones. For this work the mason uses no tool but the trowel to lay on the mortar, the scabling hammer to break off the most repulsive irregularities from the stones, and the plumb-rule to keep his work perpendicular. The line and level are equally unnecessary, as the work is independent of considerations

which are affected by them. An attentive and intelligent workman will, however, make a sound wall with this species of construction, by fitting the stones well together and packing them with as little mortar as possible, yet filling every crevice with it, and carefully bonding through to secure compactness, transversely at the least.

In coursed rubble walling, fig. 6, Plate XXI., the line and level are used, the work is laid in courses, each course being carefully brought up to the same level in itself, though no attention is paid to uniformity in the heights of the different courses. For this species of walling the stones are generally thoroughly dressed by the workman in the gross before he begins building. He is careful to get parallel beds to them, and he brings the best face of each stone to a tolerably even surface at right angles to the beds; the ends, too, receive some little attention, and for this purpose he uses an axe in addition to his scabling hammer. The quoins in coursed rubble walling are generally built with peculiar neatness and precision, and they are set to serve as gauge courses for the rest. This, when well executed, makes a sound and excellent wall. It presents, however, rather a rough and homely appearance, and in finer works must be covered with stucco or cement, or faced with ashlar.

Ashlar is an external rind of gauged stones in equal courses, having tooled or closely-fitting joints to give a wall a neat and uniform appearance; it is axed, tooled, or rubbed, as may be thought most in character with the structure, or that part of it to which it is to belong. Ashlar stones, or ashlars as they are commonly called, are made of various sizes on the surface, as the character of the edifice may require or convenience demand, and vary in thickness from 5 to 8 or 9 inches. Some of the ashlar stones must, it is clear, be used transversely as bond stones, or the facing, having nothing to connect it with the wall behind, would soon totter and fall. Bond stones are generally put in alternate courses, with the backing to the jambs of openings, such as windows, and oftener, if these do not recur within a length of 5 or 6 feet; the bond stones themselves, too, should not fall in the same vertical chain, except when they are in the jambs of openings, but should break in their alternate courses. Ashlar is commonly set in fine mortar or in putty. It is generally recommended that ashlars should not be made regular parallelopipeds, but run back irregularly to tooth in with the backing, the vertical joints being left open from about an inch within the face of the wall, and the upper surface or bed of the stones made narrower than, though perfectly parallel to, the lower. These things may exert a slightly beneficial influence under some circumstances; but the mode of construction involved is so radically bad, that unless the backing is set in a quick-setting cement, or is so well packed as to be proof against its general tendency to settle away from the ashlar facing, no method of the kind can materially improve it. A well-compacted wall of coursed rubble, the courses being frequently made up of whole stones and faced with ashlar, may be made tolerably sound and trustworthy. Brick backing, with ashlar facing, cannot be considered as good, though it has the advantage of not requiring battening and lathing for inside plastering, as the stone-backed wall does. Uncoursed rubble with ashlar has all the disadvantages of both the preceding, with nothing to recommend it before either of them. A thin inner brick wall, like a hollow wall, is very often necessary, where it is anticipated that the rain will be beaten through the stone-work by the impetuosity of the wind. The settlement of these two kinds of work during the setting of the mortar is so different, that the walls often separate; or where this is prevented by bond stones, the walls bulge outwards and bear unequally on their base. These evils are best prevented by using as little mortar as possible in the interior parts of the wall, and not raising the wall a great height at a time.

In order to give an uniform colour to a stone or ashlar wall, masons mix up pounded chippings of the stone they have used with some lime, salt, whiting, and size, and a little ochre, with which they colour the stone as they clean off the work. It is called badigeon, and is used also on plastered walls, where joints are sometimes drawn in colour to represent stone-work. Small defects in the stone are filled up with the same, or with shell-lac and the pounded stone.

There are many different sorts of walling or modes of structure arising from the nature of the materials furnished in various localities. That of most frequent occurrence, perhaps, is a manner in which either squared, broken, or rounded flints are used. These depend entirely on the care with which they are arranged, and on the mortar with which they are compacted, as also on a coursed chain, which is commonly introduced at short intervals of larger stones or of bricks, to act as a bond; the quoins, too, in this species of structure are generally constructed of dressed stones or of brick. Another sort of building is that of Pisé work, which from its economy as well as its general utility, has been much used in various countries. It consists of merely compressing earth in moulds or cases, whereby houses of two or three stories in height can be raised. Strong earths, with a mixture of small gravel, form the best material. The earth cannot be used when it is either too dry or too wet; when prepared it is put into the moulds and rammed down. The openings for the doors and windows must be left at the time of building the walls; and the openings have to be faced with wood for hanging the doors or for inserting the frames. The exterior decorations are best made of stone or brick; wood will not unite very well with the Pisé; the flues are also formed of brickwork. The exterior should be cemented or rough-casted, which should only be done when the wall is quite dry, or the cement will be cast off by the damp. The walls require to be bonded at the angles by thin rough planks to each course of about 3 feet in height, and the interior walls to be likewise so tied to the main ones. Such work has lasted over a century and a half. It was extensively practised at Lyons and in the south of France during the last century. Several attempts have been made of late years to build concrete walls for houses, and with much success. The process is similar to that already described. One patentee has been enabled to produce a cheap material wherewith he has built every part of a house,—walls, floors, staircase, and a flat roof, and even the doors, the material being set in an iron frame, thus rendering the house perfectly incombustible. Several such "monolithic doors" have lately been put up in London in place of plate iron doors.

Whatever objections lie against bond timber in brickwork apply with equal force at least to the use of it in stone walls. Hoop-iron bond is not only available in all kinds of stone walling, including the highly-wrought close-jointed kind, but it is invaluable, as it may be used both longitudinally and transversely as it may in brickwork; whilst it compels the building mason to bring his work up to a true and fair bed as often as the bond is to be laid in it. Discharging arches, it must be evident, are as necessary in and to stone walls as to walls of brick, and they may be treated much in the same manner. See fig. 10, Plate XX., and fig. 4, Plate XXI.

When walls are not entirely of masonry, in the ordinary course of economic building, stone is frequently used for copings, cornices, string and blocking courses, sills, landings, pavings, curbs, steps, stairs, hearth-stones and slabs, and chimney-pieces; to these may be added quoins and architectural decorations or dressings for windows, doors,

&c., though both the former and latter are not unfrequently executed in plaster composition or cements. Quoins. Quoin-stones are gauged and wrought blocks with parallel beds and vertical faces, placed on the angles of buildings in the Greek, Roman, and Italian styles, with the intention of adding to their beauty and strength, as in fig. 7, Plate XXI.; they are used in all kinds of walling, and are generally made to project before the face of that to which they are attached, mostly with a weathered angular joint, or with a rectangularly grooved or moulded one. The quoins are coursed with the rest of the wall if it be of stone, and are made to occupy the exact space of a limited number of courses of brick in a brick wall, or of flints where these are used. Copings. Copings in Italian work to cover walls, parapets, &c., are worked with a plain horizontal bed, two vertical faces, and an inclined or weathered back or upper surface,—either forming an acute angle with the outer and wider, and an obtuse angle with the inner and narrower face, to throw the water off, shown at *a* fig. 9, Plate XXI.; or sloping to both sides from the middle, as at *b*; the latter is technically termed saddle-back coping. In both cases they are made to project over the wall or parapet on both sides; and in the projected part of the bed under the edge or edges towards which the inclination is given, a channel or groove, called a throat, is cut, to intercept the water in its Throating. inclination to run inwards to the wall. On gables or other inclined planes the coping is neither weathered nor throated, as the water is necessarily impelled along its course to the lower end, and not over the sides. It is a curious circumstance that the mediæval designers rarely made their copings to project on the inside of a parapet, as shown in fig. 16, so that the exterior projection, which was returned up, was perhaps intended as much for effect as use. To protect the separate stones of a coping course from the danger of being displaced by high winds or other accidental causes, and to form a chain through its whole length, the stones are linked together Cramps. by cramps of copper or iron let into their backs and run with lead. These metals, however, especially the iron, for the most part act very injuriously, from their exceeding sensibility to atmospheric changes, and their greater or less tendency to oxidation; indeed, the stone invariably suffers more than the work Joggles, &c. benefits from the metal cramps. Tenons, dowels, joggles, or dovetails, of stone, of hard word, or of slate set in Portland cement, applied so as to be protected from the weather, are far better, and would answer every desirable purpose sufficiently. Lead dowels, when small, are occasionally used. The value of joggling and doweling to stone-work is well exemplified in the construction of Eddystone lighthouse. Cornices. Cornices are but ramified copings, and are or may be subjected to the same general laws. Care must be taken, however, in arranging them, that their centre of gravity be not brought too far forward, in the anxiety to project them sufficiently, lest they act injuriously on the wall by pressing unequally, and their own seat be also endangered. String course. String courses economically, in contradistinction to architecturally, are meant to protect a set-off in a wall, by projecting over its lower face in the manner of a coping, as in fig. 7, Plate XXI., at *c*; the beds are worked parallel, and the outer face vertical or at right angles to them, but so much of the upper surface is weathered or sloped off as protrudes from the upper part of the wall to carry the water off; and, for the reason above stated with regard to copings, the lower bed just within the outer face is throated. A stone string course, cramped or dovetailed in the bed, forms an excellent chain round a brick wall; but the part of it in the wall should be of the exact height of one, two, or more courses of brickwork. The woodcut, fig. 17, is a usual cornice or string course in the later period of mediæval art in England. Blo[cking] cou[rse]. A blocking course is either a very thick string projecting over or flush with the face of the lower part of the wall to cover a set-off; or it is a range of stone over a crowning cornice to bring the centre of gravity more in on the wall than it otherwise would be; in the former case it is treated exactly as a string, excepting that, if it be flush below, there is no occasion for a throat; in the latter it has a horizontal case bed, parallel vertical sides, and a weathered back or upper surface. Sill[s]. Sills are weathered and throated like the parts of a string course, Plate XXI., fig. 7, *a* and *b*; yet in mediæval work they may be seen flush with the upright of the wall. They are laid across window openings as a base to the sash-frame; distinct sills in the same line may, indeed, be considered as an intercepted string course. In the ordinary practice of building, window sills are seldom set in brick walls until they are absolutely required to set the sash-frames on; or they are set but not bedded, except at the ends. The object of this is to prevent any settlement that may occur in the piers from breaking the sills across on the unyielding part of the wall under the windows. A necessity for this, however, can only arise from bad construction; for with a good bond in the brickwork, all would settle together, and the sills might be completely bedded across at once.

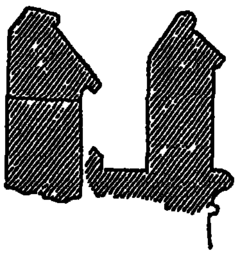

Fig. 16.—Copings.

Fig. 17.—Cornice.

Lan[dings]. Landings are platforms of stone, either over an area before a door, at the head of a flight of stairs, or as the floor of a balcony. They are made four, five, six, or eight inches in thickness, according to their extent and bearing; if not one piece of stone they are of nicely jointed pieces joggled and plugged together, and are worked on the face and edges just as their situation may demand. They should also be very carefully pinned into the walls. Fig. 18 will show the danger, should they not be so, through the full length of their insertion. If the front edge be pinned up, as at A, but a vacancy be left, as at B, the point C will become the fulcrum of a lever, and the landing have a tendency to turn at that point, and to break at the edge C. Every step and landing should have 8 inches hold in a brick wall. All landings should be well joggled; the joint joggles made as at *a*, fig. 19, is called by workmen a *he*, and that at *b* a *she* joggle. An accident at the Polytechnic Institution in London arose, no doubt, from the carelessness of the workmen, who put two landings together, in which two she-joggles were worked, as in fig. 20, and filled the open space with plaster. There happened to be a large fossil in the stone close to the wall in the landing *b*, which, having no support from the other landing *a*, gave way, and caused the destruction of the lower portion of the staircase upon which it fell.

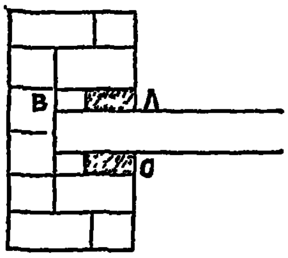

Fig. 18.—Extremity of Landing.

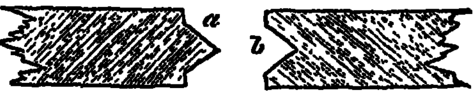

Fig. 19.—Joggles.

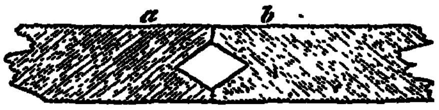

Fig. 20.—Joggles badly joined.

Stone pavings are prepared and laid in various ways. Ordinary paving is of self-faced or of tooled York; and for better purposes it is of rubbed Portland stone. For entrance halls, square stones, with the angles slightly cut off, the four spaces thus obtained being filled up by a small square of black or other coloured stone, makes a neat paving, which is replaced by marbles in best houses and public buildings, if a tesselated pavement be not required. Stone paving that is not exposed to the sun and air, if next the ground, should be laid on footings of brick or stone, or it will be constantly damp should the soil be close and clayey; but in yards, open areas, &c., it may be laid on the ground, bedded in sand, and jointed with mortar or cement. Stone-paved floors should be formed on brick arches, or on a timber floor prepared for the purpose; the latter, however, is a very bad mode of supporting paving, as the impression derived from the presence of the stone is, that the floor is incombustible; but if it be bedded on combustible material, the danger to human life in the event of fire is greater than if the stone paving did not exist at all. It is worked, cut, and set more or less expensively, according to circumstances. A curb is a range or course of thicker and stronger stone to bound a pavement, and is either flush with the paving showing as a step on its outer edge, or is raised above it to receive a balustrade, and shows on the outer side as a blocking course: in the latter situation it is generally joggled and plugged in the joints. The term step or steps alone is usually understood to mean external steps, whether arranged in long or short flights, or the single step in a doorway into which the door-frame is tenoned. A step should have a plain horizontal bed, and a very slightly weathered tread or upper surface,—the front or riser worked plain and vertical, or with a moulded nosing, and the back sunk with a joggle or bird's-mouth joint to receive the step or landing above or behind it. Steps for areas or back courts are often made of 2 or 2½ in. stone for the tread, the riser being formed of a 4½ or 5 in. stone, both tailed into a wall at one or both ends. This is much lighter in effect. Slate is sometimes used for the treads.

Stairs are but a flight or combination of steps used internally, and the general principle of designing staircases, as regards the rise and tread of steps, setting out curves, curtails, landings, &c., are given in the part treating of joinery. The chief difference between these and other staircases consists in the fixing, the one being framed with wooden strings, while the other have no strings, but are supported entirely by the walls. If there be a wall at each end, they are simply built in at the time the work goes up; but if they are supported at one end only, they are called geometrical stairs, and depend entirely on their being securely wedged into the wall; on which and on the support each derives at one edge from the step below, they wholly rely. If they are square in section, they are called solid steps; but as the under side or soffit, then, is irregular, it is usual to make the steps of somewhat a triangular shape, so as to present a continued soffit. In this case they are called arris, or feather-edge steps. Care should be taken that there are no sudden or irregular changes in the curves. These may be easily avoided by the method shown in the portion relating to joinery for the easing of the curves and ramps in handrails.

In houses built of stone the flues are usually formed in brickwork. The chimney-pieces consist of plain jambs, or boxings, or other vertical sides more or less decorated and moulded, and of the architrave or transverse covering or mantel, fig. 8, Plate XXI., with its shelf or cornice. The parts of a chimney-piece are generally put together with an adhesive plaster or cement, and affixed to the wall or chimney-breast behind with cramps, holdfasts, and plugs. The material of which chimney-pieces, if not of wood, are composed, varies from the coarsest stone to the finest marble; and the labour on them varies to a still greater extent.

Decorative masonry.

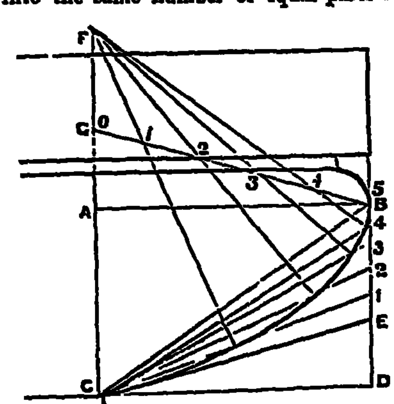
Masonry to receive architectural decorations is generally worked into the walls as they are carried up; but as they are seldom homogeneous either in matter or construction, the result is mostly the converse of what it purports to be, for the work is more frequently weakened than strengthened by the decorative masonry. Stones of which columns are to be composed, whether each column is to be of one stone or more, are generally roughly boasted out before they are set, and are finished afterwards to traversing moulds and templets with a plumb-rule, whose sides are cut to the diminution obtained from the bottom and upper diameters, whatever it may be. Flutes are cut at the same time and in the same manner. The beds of the joints in columns should be worked with the greatest precision, so as to obtain parallel planes, that they may fit firmly and closely together; they must not, however, be worked hollow to make a close joint externally, or the arrises will chip off. It is considered a good plan, where the columns are large, to put a piece of thin milled lead between the beds, cut circular, and extending to within a short distance of the surface, and that the rest be filled with a fine adhesive putty, made as nearly of the colour of the stone as possible. This makes a solid bed, and protects the arrises effectually; but it will not do so well for slight columns, because it narrows the bed so materially. A joggle or dowel of hard wood, slate, or cast-iron let into the core might be a sufficient counteraction, and it would certainly add to the stability of a polylithic shaft. The other parts of a columnar composition may be sufficiently cramped and joggled together with wood and metals according to the situation, though it may be again remarked, that neither wood nor metal should be used, unless it can be protected from access even of the atmosphere.

Columns.

Greek and Roman mouldings.

Sections for Roman mouldings are given in the part relating to joinery, but as those used in Grecian architecture are parts of conic sections, and not struck by compasses, we give a short problem by which they may all easily be set out. Both Roman and Grecian mouldings are shown on Plate XIII. of vol. ii.

Let an ovolo be the moulding required (fig. 21), the height of which (to the point where the moulding curves backward) is AC or BD, and the greatest projection AB or CD; and let CE be a tangent line, or line which the curve must touch but not cut. Produce CA to F, and make AF equal to AC, and AG to ED. Divide GB BE each into the same number of equal parts as 5. Draw the co-ordinates from F and C to the respective numbers, their intersections will trace the curve. If BE be more than half the whole height, the curve is an ellipse; if exactly half the height, it is a parabola; and if BE be less than half BD, the curve will be a hyperbola. All other mouldings can be drawn by this method, it being remembered that cymas, ogees, and all reflex curves, must be divided and drawn in two separate portions.



G. 21.—Construction of Ovolo.

Mediæval mouldings.

The mouldings in mediæval architecture differ entirely from those of other styles. They are chiefly formed by a combination of curves stopped by right lines or worked into other curves and hollows. The mouldings differ in

each of the several periods of the style in England, and also in the variations of the style as practised here and in each country on the Continent. We insert an outline, fig. 22, of a window jamb at Sleaford church, Lincolnshire, to show the forms and combination of an example during the Decorated period. A full description of those used in each style would exceed our limits, nor, indeed, is it a subject within the scope of this article. They are sometimes set out with the compasses, and many often appear to have been drawn by eye. We must refer our readers to the works of Professor Willis, F. A. Paley, and of J. H. Parker, for any details required about them. A very curious treatise was published by Professor Willis, called the *Architectural Nomenclature of the Middle Ages*, which goes at great length into the subject. A bead or astragal seems to have been called a bowtelle;

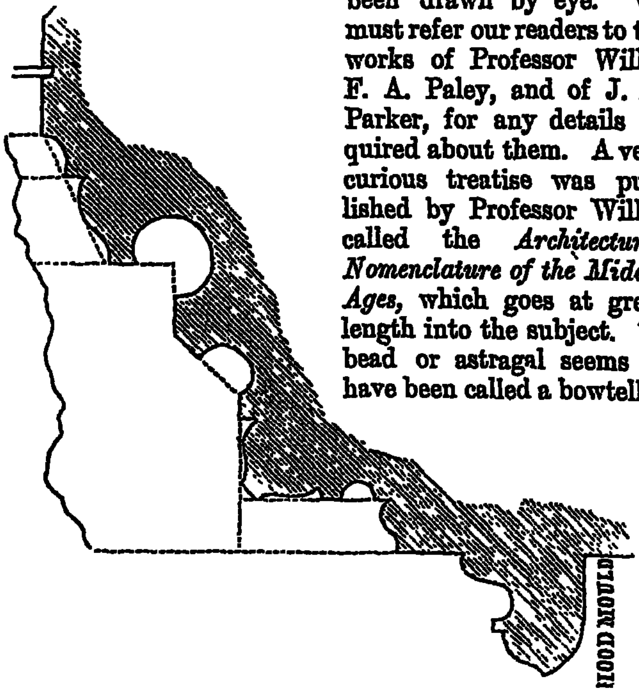


FIG. 22.—Outline of Window Jamb at Sleaford Church.

a torus, a grete bowtelle; a hollow or scotia, a casement; an ogee, a ressaunte, and so on.

Working the mouldings.

The methods of working mouldings in the stones at the builder's command have been already noticed at the commencement of this section. The soft stones and marbles are easily shaped into mouldings with the chisel and the mallet, and are sawn and the surfaces even finished with a plate having a fine edge. These stones will take mouldings of minuter character than the harder stones, which have to be worked with force, and require pointed tools to form the faces. The hardest material, granite, again, has to be stunned with heavy picks to make an impression, so that only bold ornaments have a good effect; much money has been thrown away in details more suitable for softer materials. Good effect is obtained by the contrast of axed and polished surfaces. A designer should visit the places where buildings in granite have been erected for a knowledge of a proper application of that material.

Arches.

The earliest arches were circular and, of course, easily set out. But as the Pointed styles came in, several methods were used for describing them. Pointed arches may be classed as—1st, lancet; 2d, equilateral; 3d, depressed;

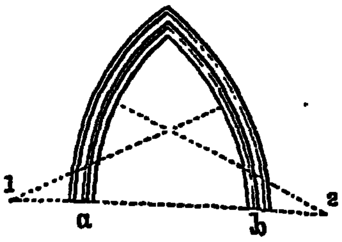

FIG. 23.—Lancet Arch.

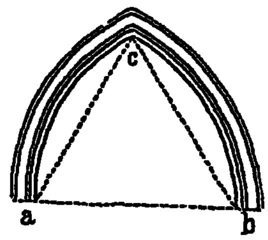

FIG. 24.—Equilateral Arch.

and 4th, four-centred or Tudor. In the first the centres, as 1, 2, in fig. 23, are outside the arch *a b*. At Westminster Abbey the arches of the choir are so acutely pointed that the distances 1*a* and 2*b* are nearly two-thirds of the entire opening *a b*. In the nave at York the points are without the arch at a distance of about one-fifth the opening *a b*. In equilateral arches the centres are exactly on the points *a b* in fig. 24, so that the apex *c*, joined to *a* and *b*, will form an equilateral triangle. The nave arches at Wells are of this description, and also those at Lincoln (see vol. ii. Plate XVIII. fig. 1). In later times the arches were of lower pitch, as fig. 25, and then, of course, the centres 1 and 2 were within the arch *a b*. At Salisbury Cathedral the distance *a*1 is one-sixth of *a b*, while in the choir at Lincoln (vol. ii., Plate XVIII., fig. 2) it is as much as two-fifths. To describe arches which shall be similar to one another throughout a building, however the openings may

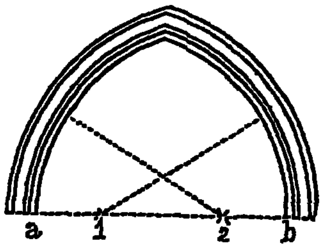

FIG. 25.—Depressed Arch.

differ, this principle must always be borne in mind, that the centres are to be always distant from the points *a b* by some aliquot portion of the whole opening. This is the more important, as the lines of tracery will not fall into their proper places except the arches are set out upon some regular principle. If the arches are not equilateral, some distance from each point *a b* should be first determined on (say one-third the opening *a b*), and after this, whatever the span of the other arches may be, one-third its own opening is to be taken from the points *a b*, as the centres from which to strike its curves. The only exception is that, in mediæval buildings, the arches to the doorways are frequently somewhat flatter than those of the windows. In the Tudor period the arches are very frequently drawn from four centres instead of two. As there has been great misapprehension as to four-centred arches, some persons treating them as parts of conic sections, whereas they are really parts of segments of circles, it is thought well to give two methods of describing these arches.

Four-centred

First, when the width AB, fig. 26, of the arch, and the apex height OC, are given, and a tangent to the upper circle as CD. In this case draw AD perpendicular to AB, and set out A1 equal to AD; draw C3 perpendicular to CD, and make CE equal to AD or A1; join 1E and bisect the same as shown by a perpendicular meeting CE produced in 3; join 3 1 and produce towards F, then 1 and

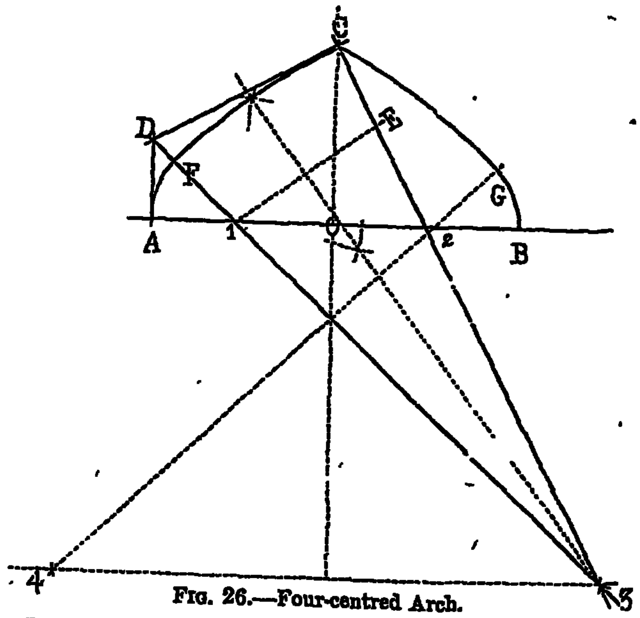

FIG. 26.—Four-centred Arch.

3 will be the centres for half the arch; and, transferring the points across, 2 and 4 will be the centres for the other half. In the second case, when the width AB and the height OC, and the centres of the small circles 1, 2, are given. Make AD equal to A1, join CD (which will be a tangent to the upper curve), draw C3 at right angles

thereto, make CE equal to AE, join BE, bisect the same, and proceed as before. The points FG, as has before been explained, are the points where the circles will meet each other. The joints to these arches will all radiate to their respective centres.

[Win]dow [trac]ery. Specimens of various sorts of the tracery which adorn the windows of the mediæval periods, and are in fact their greatest glory, are shown in Plates XVIII., XIX., and XX. of vol. ii. The designs for tracery are almost infinite, and the various methods of setting them out would fill a volume. But although they display such ingenuity and fancy that one would think the design to be quite arbitrary, it will be found that they are all, or very nearly all, set out on the principle of geometrical intersections. An example will show the principles on which the mediæval architects proceeded to describe the tracery, and also the method of finding the joints of the various pieces of stone.

Let $a\,b$ (fig. 27) be the opening of the arch; as there are to be two mullions, divide the same into three equal parts, as $a\,c$, $c\,d$, $d\,b$; then determine the points from which to strike the arch. In this instance, for the sake of simplicity, we make it equilateral (as in fig. 24); a and b then are the centres for striking the main

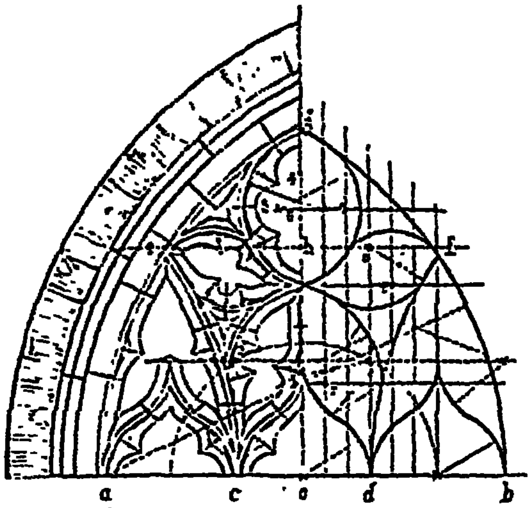

FIG. 27.—Construction of Window Tracery.

arch $a\,e\,g$, $b\,f\,g$, and the height $o\,g$ is that of an equilateral triangle. Produce the springing line, and the same opening of the compasses through c and d will give the principal inner branches of the tracery $e\,c$, $d\,f$. From the centre o, with an opening extending to the middle of the lights $a\,c$, $d\,b$, strike a semicircle; raise perpendiculars from d and c to 1 and 2; draw a line through 1 and 2; on this and the springing line will be found the centres of the lower ogees; bisect the part of $g\,o$ cut off by 1 2 in h, which is in fact the same thing as dividing the whole height $o\,g$ into three; divide $h\,g$ into three parts, at 3 and 4; through 3 draw a horizontal line, and set off from 3 distances one-third of the width $o\,d$, or draw the perpendicular lines as shown, which is better; then 5 and 6 will be the centres of the upper quatre-foil. From the line 1 2, on the same perpendicular as last, set down similar points, as at 7. These will be the centres for the lower subdivision as shown. Next draw $e\,h\,f$ and subdivide by similar perpendiculars, and where the lines intersect, as at 8, will be the centres for the upper subdivisions. The lines thus drawn will form a species of skeleton diagram, as shown on the right side of fig. 27, which is called the *element of the tracery*, and is in fact the centre line of the mullion, as shown by a, fig. 28. On each side of this, using always the same centres for the same branches, draw lines, showing the face (or what the workmen call the *nose*) of the mullion, and answering to $b\,c$; and then others answering to the sides of the mullion, as $d\,e$. Any other mouldings upon their sides or faces may be drawn in like manner. Put in the cusping as shown, and the tracery is complete. The practical stone-mason will take care never to make a joint where there is an angle of any sort, as the point of a cusp. In all cases the joints must tend to the centres of the circles from which they are struck, and where the lines branch off in two directions, the joints must not be in one line, but must tend in two, or as many directions as there are branches, and each to the centre of

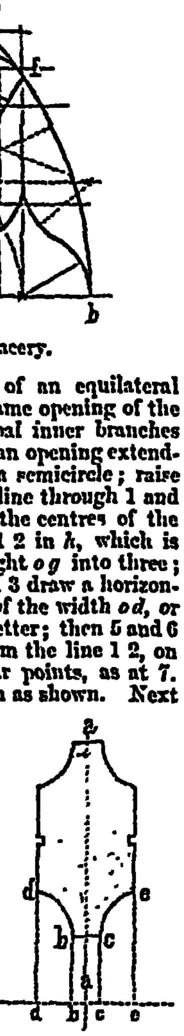

FIG. 28.—Mullion.

such respective branch. When the lines are perpendicular, as at c and d, and at the joint below h, the joints are horizontal. A close inspection of fig. 27, where they are carefully drawn, will fully elucidate the matter. The elaborate west window at York Cathedral (see Plate XVIII. of vol ii.) is entirely set out on this principle; and so is the still more remarkable instance, the eastern window at Carlisle, which is composed of 86 pieces of stone, and the design for which is drawn from 263 centres.

All the upper construction of windows and doors, and of aisle arches, should be protected from superincumbent pressure by strong relieving arches above the labels, as shown by the dark tints in fig. 27, which should be worked in with the ordinary masonry of the walls, and so set that the weight above should not press on the fair work, in which case the joints of the tracery, &c., will sometimes flush or break out.

In mediæval vaults the crowns $a\,b$, $c\,d$, are not level, but all have a slight curve or spring, as shown in fig. 29, and the filling-in between them also is slightly curved, so as to partake in some degree of the character of the dome as well as of the groined arch; and for the most part the ribs in early vaulting are not true segments of ellipses, but approximations drawn by the compasses. The triumph of mediæval stone-masonry, however, is that species of groin known as fan-vaulting. It is unlike that of any other age or time. The roofs of King's College Chapel at Cambridge and of Henry VII.'s Chapel at Westminster are eminent and late examples. The earliest are supposed to be in the cloisters of Gloucester Cathedral. It is impossible in our limited space to give demonstrations of them, and we must refer our readers to the admirable treatise on the subject by Professor Willis, published in the first volume of the *Transactions* of the Royal Institute of British Architects. The filling-in between the ribs of mediæval groins is generally of clunch, or of some soft stone, over which a layer of concrete is sometimes placed in such manner as to bind all together and to resist the thrust. Mediæ[val] vaultin[g].

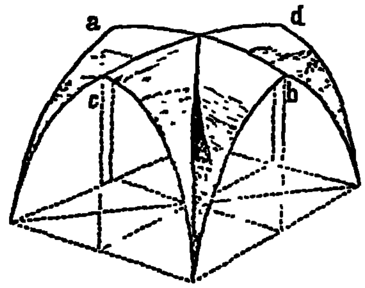

FIG. 29.—Mediæval Vaulting.

The bold and beautiful termination to mediæval towers, which we call a spire, and the French call *flèche*, is another proof of the skill of the mediæval masons. These are generally octagonal, and rise partly from the wall of the tower and partly from arches thrown angle-wise from wall to wall inside, to cut off the corners, as it were, and afford a springing to the spire. The wonder of these constructions is their extreme lightness and thinness. The top of the spire at Salisbury is 411 feet from the ground, of which the tower takes up 207 feet, leaving, of course, 204 feet for the height of the spire itself; this is only 9 inches thick at the bottom, diminishing to 7 inches, or on an average only about the 300th part of its height. It has been attempted to show mathematically that the joints of a spire would be stronger if formed at right angles to its face; but they would then slope inwards and hold the wet, which in sudden frosts would do most serious injury; practically, therefore, it is found best to lay the courses on a level bed. They should, however, be frequently doweled and cramped together, but not with metal, for the extreme thinness of the stone would soon cause it to rust and break out the stone. Spires.

The principal publications on masonry are as follows:—

Guide to Railway Masonry, 8vo, 1839–46; and *Practical Masonry, Bricklaying*, &c., 4to, 1830; Dobson, *Rudimentary Treatise on Masonry*, 1849, 1856; Robson, *Masons', Bricklayers', and Decorators' Guide*, 4to, 1862.

Foreign.—De l'Orme, *Nouvelles inventions pour bien bastir*, &c., fol., 1561; Jousse de la Flèche, *Secrets d'Architecture*, fol., 1642; Bosse, *La Pratique du trait pour la Coupe des Pierres*, fol., 1643; Derrand, *Des Traits et Coupe des Voutes*, fol., 1643; De la Rue, *Traité de la Coupe des Pierres*, fol., 1728; Frézier, *Traité de Stéréotomie*, 4to, 1737; and *Eléments de Stéréotomie*, 1759; Simonin et Delagardette, *Traité de la Coupe des Pierres*, 4to, 1792; Douliot, *Traité speciale du Coupe des Pierres*, 4to, 1825; *Vorlegeblätter für Maurer*, fol., 1835; Adhémar, *Traité de la Coupe des Pierres*, fol., 1836–40; Normand, *Épures d'Escaliers en Pierre*, 4to, 1838; Le Roy, *Traité de Géometrie descriptive*, 4to, 1850; Claudel et Laroque, *Maçonnerie Pratique*, 8vo, no date; the article *Maçonnerie* in the various *Encyclopédies*; and the general treatise by Rondelet, *L'Art de bien bâtir*, with supplement by Blouet, fol., 1842–46.

Sawyer-work.

The labour of the sawyer is applied to the division of large pieces of timber or logs into forms and sizes to suit the purposes of the carpenter and joiner. His working-place is called a saw-pit, and his almost only important tool a pit-saw. A cross-cut saw, axes, dogs, files, compasses, lines, lamp-black, black-lead, chalk, and a rule, are all accessories which may be considered necessary to him.

The facility with which sawing whole timber is now done by the aid of the upright saw-frame, and smaller timber by the circular-saw bench, has in large factories and workshops caused the saw-pits to be out of date; timber after it has been cut at the mills can be again reduced into sizes and scantlings at a rapid rate, and with great exactitude and little labour. In some country parts, however, the saw-pit is still used. Unlike most other artificers, the sawyer can do absolutely nothing alone; sawyers are therefore always in pairs,—one of the two standing on the work, and the other in the pit under it. The log or baulk of timber being carefully and firmly fixed on the pit, and lined for the cuts which are to be made in it, the top-man standing on it, and the pit-man below or off from its end, a cut is commenced, the former holding the saw with his two hands by the handle above, and the other in the same manner by the box handle below. The attention of the top-man is directed to keeping the saw in the direction of and out of winding with the line to be cut upon, and that of the pit-man to cut down in a truly vertical line. The saw being correctly entered, very little more is required than steadiness of hand and eye in keeping it correctly on throughout the whole length. In the operations of the carpenter and joiner much depends on the manner in which the sawyers have performed their part. The best work on the part of the carpenter cannot retrieve the radical defects in his materials from bad sawing; and although the joiner need not allow his work to suffer, bad sawing causes him great loss of wood and immense additional and otherwise unnecessary labour. Planks or boards, and scantlings, on coming from the saw-pit, should be as straight and true in every particular, except mere smoothness of surface, as if they had been tried upon the joiner's bench; and good workmen actually produce them so. Saw-mills, too, by the truth and beauty with which they operate, show the sawyer what may be effected; for though he can hardly hope to equal their effect, he may seek to approach it.

Carpentry.

Carpentry or carpenter's work has been divided into three principal heads, namely, *descriptive*, *constructive*, and *mechanical*. The first shows the lines or methods for forming every species of work by the rules of geometry; the second comprises the practice of reducing the timber into particular forms, and joining the forms so produced so as to make a complete whole according to the intention or design; and the third displays the relative strength of the timbers and the strains to which they are subjected by their disposition. Here, we have merely to describe the practical details of carpenters' work in the operations of building. The carpenter works in wood, which he receives from the sawyer in beams, scantlings, and planks or boards, which he cuts and combines into bond-timbers, wall-plates, floors, and roofs. He is distinguished from the *joiner* by his operations being directed to the mere carcass of a building—to things which have reference to structure only. Almost everything the carpenter does in and to an edifice is absolutely necessary to its stability and efficiency, whereas the joiner does not begin his operations until the carcass is complete; and every article of joiners' work might at any time be removed from a building without undermining it or affecting its most important qualities. Certainly, in the practice of building, a few things do occur regarding which it is difficult to determine to whose immediate province they belong; but the distinction is sufficiently broad for general purposes. The carpenter, with the bricklayer or mason and some of the minor artificers, constructs the frame or hull; and the joiner, with the plasterer and others, decorates and rigs the vessel. On the former the actual existence of the ship depends, and on the latter depends her fitness for use.

The carpenter frames or combines separate pieces of timber by scarfing, notching, cogging, tenoning, pinning, and wedging. The tools he uses are the rule, the axe, the adze, the saw, the mallet, hammers, chisels, gouges, augers, wimbles, pincers, hook-pins, a square, a bevel, a pair of compasses, and a gauge, together with the level, square, and plumb-rule; besides these, planes (for making grooves, rebates, and mouldings), gimlets, pincers, a sledge-hammer, a maul or beetle, wedges, and a crow-bar may be considered useful auxiliaries, though they are not absolutely necessary to the performance of works of carpentry. Planing and other machines are used to diminish the great manual labour of working the surface of planks and boards, and of moulding, tenoning, and other similar operations; and so elaborate are some of these machines, that a four-panelled door can now be made complete in a couple of hours, which formerly was considered a good day's work for a man. Circular-saws are employed for working up larger timbers; and for ripping up boards or scantlings of moderate thickness, they are now used in all workshops. Tools.

The fir timber in general use is imported from Memel, Riga, Dantzig, and Sweden. Memel timber is the most convenient for size, Riga the best in quality, Dantzig the strongest, and Swedish the toughest. Riga timber can always be depended upon. Red pine may be used wherever durability and strength are objects; Quebec yellow pine for light dry purposes. In selecting timber, spongy heart, porous grain, and dead knots are to be avoided; the brightest in colour, and where the strong red grain appears to rise on the surface, are the best to be chosen. For joists and main timbers, the best woods are from Dantzig, Memel, or Riga; for partitions and minor timbers, American red wood, which not being so strong as the Baltic timber, must be cut to a little larger size. For sleepers, window-sills, and some parts of a roof, oak is used; for framing, Christiania deals or battens; for panelling, Christiania white deal or American yellow pine; for upper floors, Dram or Drammen and Christiania whites; for ground floors, Stockholm and Gefle yellows; for warehouse floors and staircases, Archangel and Onega planks; for best floors, St Petersburg, Onega, Dram, and Christiania battens. American deals Timber.

should not be used for floors, as they are softer; and Swedish deals are bad for framing, as they warp. For interior finishings generally, Baltic red and white woods, and the American red and yellow pine, are to be preferred.

We must first proceed to consider the means by which form in the work of the carpenter is to be secured, and the connections by which the various strains are excited and communicated. The following practical remarks on various *joints* are abridged from the article by Prof. Robison in the former editions of this work.

The joinings practised in carpentry are almost infinitely various, and each has advantages which make it preferable in some circumstances. Many varieties are employed merely to please the eye. We do not concern ourselves with these; nor shall we consider those which are only employed in connecting small works, and can never appear on a great scale; yet even in some of these, the skill of the carpenter may be discovered by his choice; for in all cases it is wise to make every, even the smallest, part of his work as strong as the materials will admit. He will be particularly attentive to the changes which will necessarily happen by the shrinking of timber as it dries, will consider what dimensions of his framings will be affected by this and what will not, and will then dispose the pieces which are less essential to the strength of the whole in such a manner that their tendency to shrink shall be in the same direction with the shrinking of the whole framing. If he do otherwise, the seams will widen, and parts will be split asunder. He will dispose his boardings in such a manner as to contribute to the stiffness of the whole, avoiding at the same time the giving them positions which will produce lateral strains on truss beams which bear great pressures; recollecting, that although a single board has little force, yet many united have a great deal, and may frequently perform the office of very powerful struts.

Our limits confine us to the joinings which are most essential for connecting the parts of a single piece of a frame (when it cannot be formed of one beam, either for want of the necessary thickness or length), and the joints for connecting the different sides of a trussed frame.

Building up beams

Much ingenuity has been bestowed on the manner of building up a great beam of many thicknesses, and many singular methods are practised; but when we consider the manner in which the cohesion of the fibres performs its office, we see that the simplest are formed on the same principles as the most refined, and they are less apt to induce false notions of the strength of the assemblage. Thus, were it required to build up a beam for a great lever or a girder, so that it may act nearly as a beam of the same size of one log, it may either be done by plain joggling, as in Plate XXII. fig. 1, A, or by scarfing, as in B or C. If it is to act as a lever, having the gudgeon on the lower side at C, we believe that most artists will prefer the form B and C. We may frequently gain a considerable accession of strength by this building up of a beam, especially if the part which is stretched by the strain be of oak, and the other part be fir. Fir being so much superior to oak as a pillar, and oak so much preferable as a tie, this construction seems to unite both advantages. But much better methods of making powerful levers, girders, &c., are obtained by trussing. Observe that the efficacy of both methods depends entirely on the difficulty of causing the piece between the cross joints to slide along the timber to which it adheres. Therefore, if this be moderate, it is wrong to make the notches deep; for as soon as they are so deep that their ends have a force sufficient to push the slice along the line of junction, nothing is gained by making them deeper; and this requires a greater expenditure of timber.

Scarfings of beams are frequently made oblique, as in Plate XXII. fig. 2; but this seems a bad practice. It begins to yield at a point where the wood is crippled and splintered off, or at least bruised out a little. As the pressure increases, this part, by squeezing broader, causes the solid parts to rise a little upwards, and gives them some tendency, not only to push their antagonists along the base, but even to tear them up a little. For similar reasons we disapprove of the favourite practice of many artists to make the angles of their scarfings acute, as in fig. 3. This often causes the two pieces to tear each other up. The abutments should always be perpendicular to the directions of the pressures. This law is also to be extended to the abutments of different pieces of a frame, and the artist must even attend to the shrinking of the timbers by drying. When two timbers abut obliquely, the joint should be most full at the obtuse angle of the end; because, by drying, that angle grows more obtuse, and the beam would then be in danger of splintering off at the acute angle.

Wedging

It is evident that the nicest work is indispensably necessary in building up a beam. The parts must abut on each other completely, and the smallest play or void takes away the whole efficacy. It is usual to give the abutting joints a small taper to one side of the beam, so that they may require moderate blows of a maul to force them in, and the joints may be perfectly close when the external surfaces are even on each side of the beam. But we must not exceed in the least degree, for a very taper wedge has great force; and if the pieces be driven together by very heavy blows, the whole is left in a state of violent strain, and the abutments are perhaps ready to splinter off by a small addition of pressure. It is not unusual to leave some abutments open enough to admit a thin wedge reaching through the beam. Nor is this a bad practice, if the wedge is of material which is not compressed by the driving or the strain of service. Iron would be preferable for this purpose, and for the joggles, were it not that, by its too great hardness, it cripples the fibres of timber to some distance. In consequence of this it often happens, that in beams which are subjected to desultory and sudden strains (as in the levers of reciprocating engines), the joggles or wedges widen the holes, and work themselves loose; therefore skilful engineers never admit them, and indeed admit as few bolts as possible, for the same reason; but when resisting a steady or dead pull, they are not so improper, and are frequently used.

Beams are built up, not only to increase their dimensions in the direction of the strain (which we have hitherto called their depth), but also to increase their breadth, or the dimensions perpendicular to the strain. Sometimes the breadth of girder is doubled, if it is thought too weak for its load, and when the thickness of the flooring must not be increased.

Masts and uprights

The mast of a great ship of war must be made bigger athwartship, as well as fore and aft. This is one of the nicest problems of the art; and professional men are by no means agreed in their opinions in regard to it. We shall content ourselves here with exhibiting the different methods. The most obvious and natural method is that shown in Plate XXII. fig. 4. It is plain that (independent of the connection of cross bolts, which are used in them all when the beams are square) the piece C cannot bend in the direction of the plane of the figure without bending the piece D along with it. This method is much used in the French navy; but it is undoubtedly imperfect. Fig. 5 exhibits another method. The two halves of the beam are tabled into each other in the same manner as in fig. 1. It is plain that this will not be affected by any unequal swelling or shrinking, because this is insensible in the direction of the fibres; but when bent in the direction $a\,b$, the beam fig. 4 is weaker than bent in the direction

c f. Each half of fig. 4 has, in every part of its length, a thickness greater than half the thickness of the beam. It is the contrary in the alternate portions of the halves of fig. 5. When one of them is bent in the direction AB, it is plain that it drags the other with it by means of the cross butments of its tables, and there can be no longitudinal sliding. But unless the work is accurately executed, and each hollow completely filled up by the table of the other piece, there will be a lateral slide along the cross joints sufficient to compensate for the curvature; and this will hinder the one from compressing or stretching the other in conformity to this curvature.

The imperfection of this method is so obvious that it has seldom been practised; but it has been combined with the other, as is represented in fig. 6, where the beams are divided along the middle, and the tables in each half are alternate, and alternate also with the tables of the other half. Thus 1, 3, 4 are prominent, and 5, 2, 6 are depressed. This construction evidently puts a stop to both slides, and obliges every part of both pieces to move together. *a b* and *c d* show sections of the built-up beam corresponding to AB and CD. No more is intended in this practice by any intelligent artist, than the causing the two pieces to act together in all their parts, although the strains may be unequally distributed on them. Thus, in a built-up girder, the binding joists are frequently mortised into very different parts of the two sides. But many seem to aim at making the beam stronger than if it were of one piece; and this inconsiderate project has given rise to many whimsical modes of tabling and scarfing.

The practice in the British dockyards is somewhat different from any of these methods. The pieces are tabled as in fig. 6, but the tables are not thin parallelopipeds, but thin prisms. The two outward joints or visible seams are straight lines, and the table 1 rises gradually to its greatest thickness in the axis. In like manner, the hollow 5, for receiving the opposite table, sinks gradually from the edge to its greatest depth in the axis. Plate XXII., fig. 7, No. 1, represents a section of a round piece of timber built up in this way, where the full line EF, GH is the section corresponding to AB of fig. 6, and the dotted line EG, FH is the section corresponding to CD. This construction, by making the external seam straight, leaves no lodgment for water, and looks much fairer to the eye; but it appears to us that it does not give so firm a hold when the mast is bent in the direction EH. The exterior parts are most stretched and most compressed by this bending; but there is hardly any abutment in the exterior parts of these tables. In the very axis, where the abutment is the firmest, there is little or no difference of extension and compression. But this construction has an advantage, which, we imagine, much more than compensates for these imperfections, at least in the case of a round mast; it will draw together by hooping incomparably better than any of the others.

Joggles of elm are sometimes used in the middle of the large tables of masts; and when sunk into the firm wood near the surface, they must contribute much to the strength. But it is very necessary to employ wood not much harder than the pine, otherwise it will soon enlarge its bed and become loose, for the timber of these large trunks is very soft.

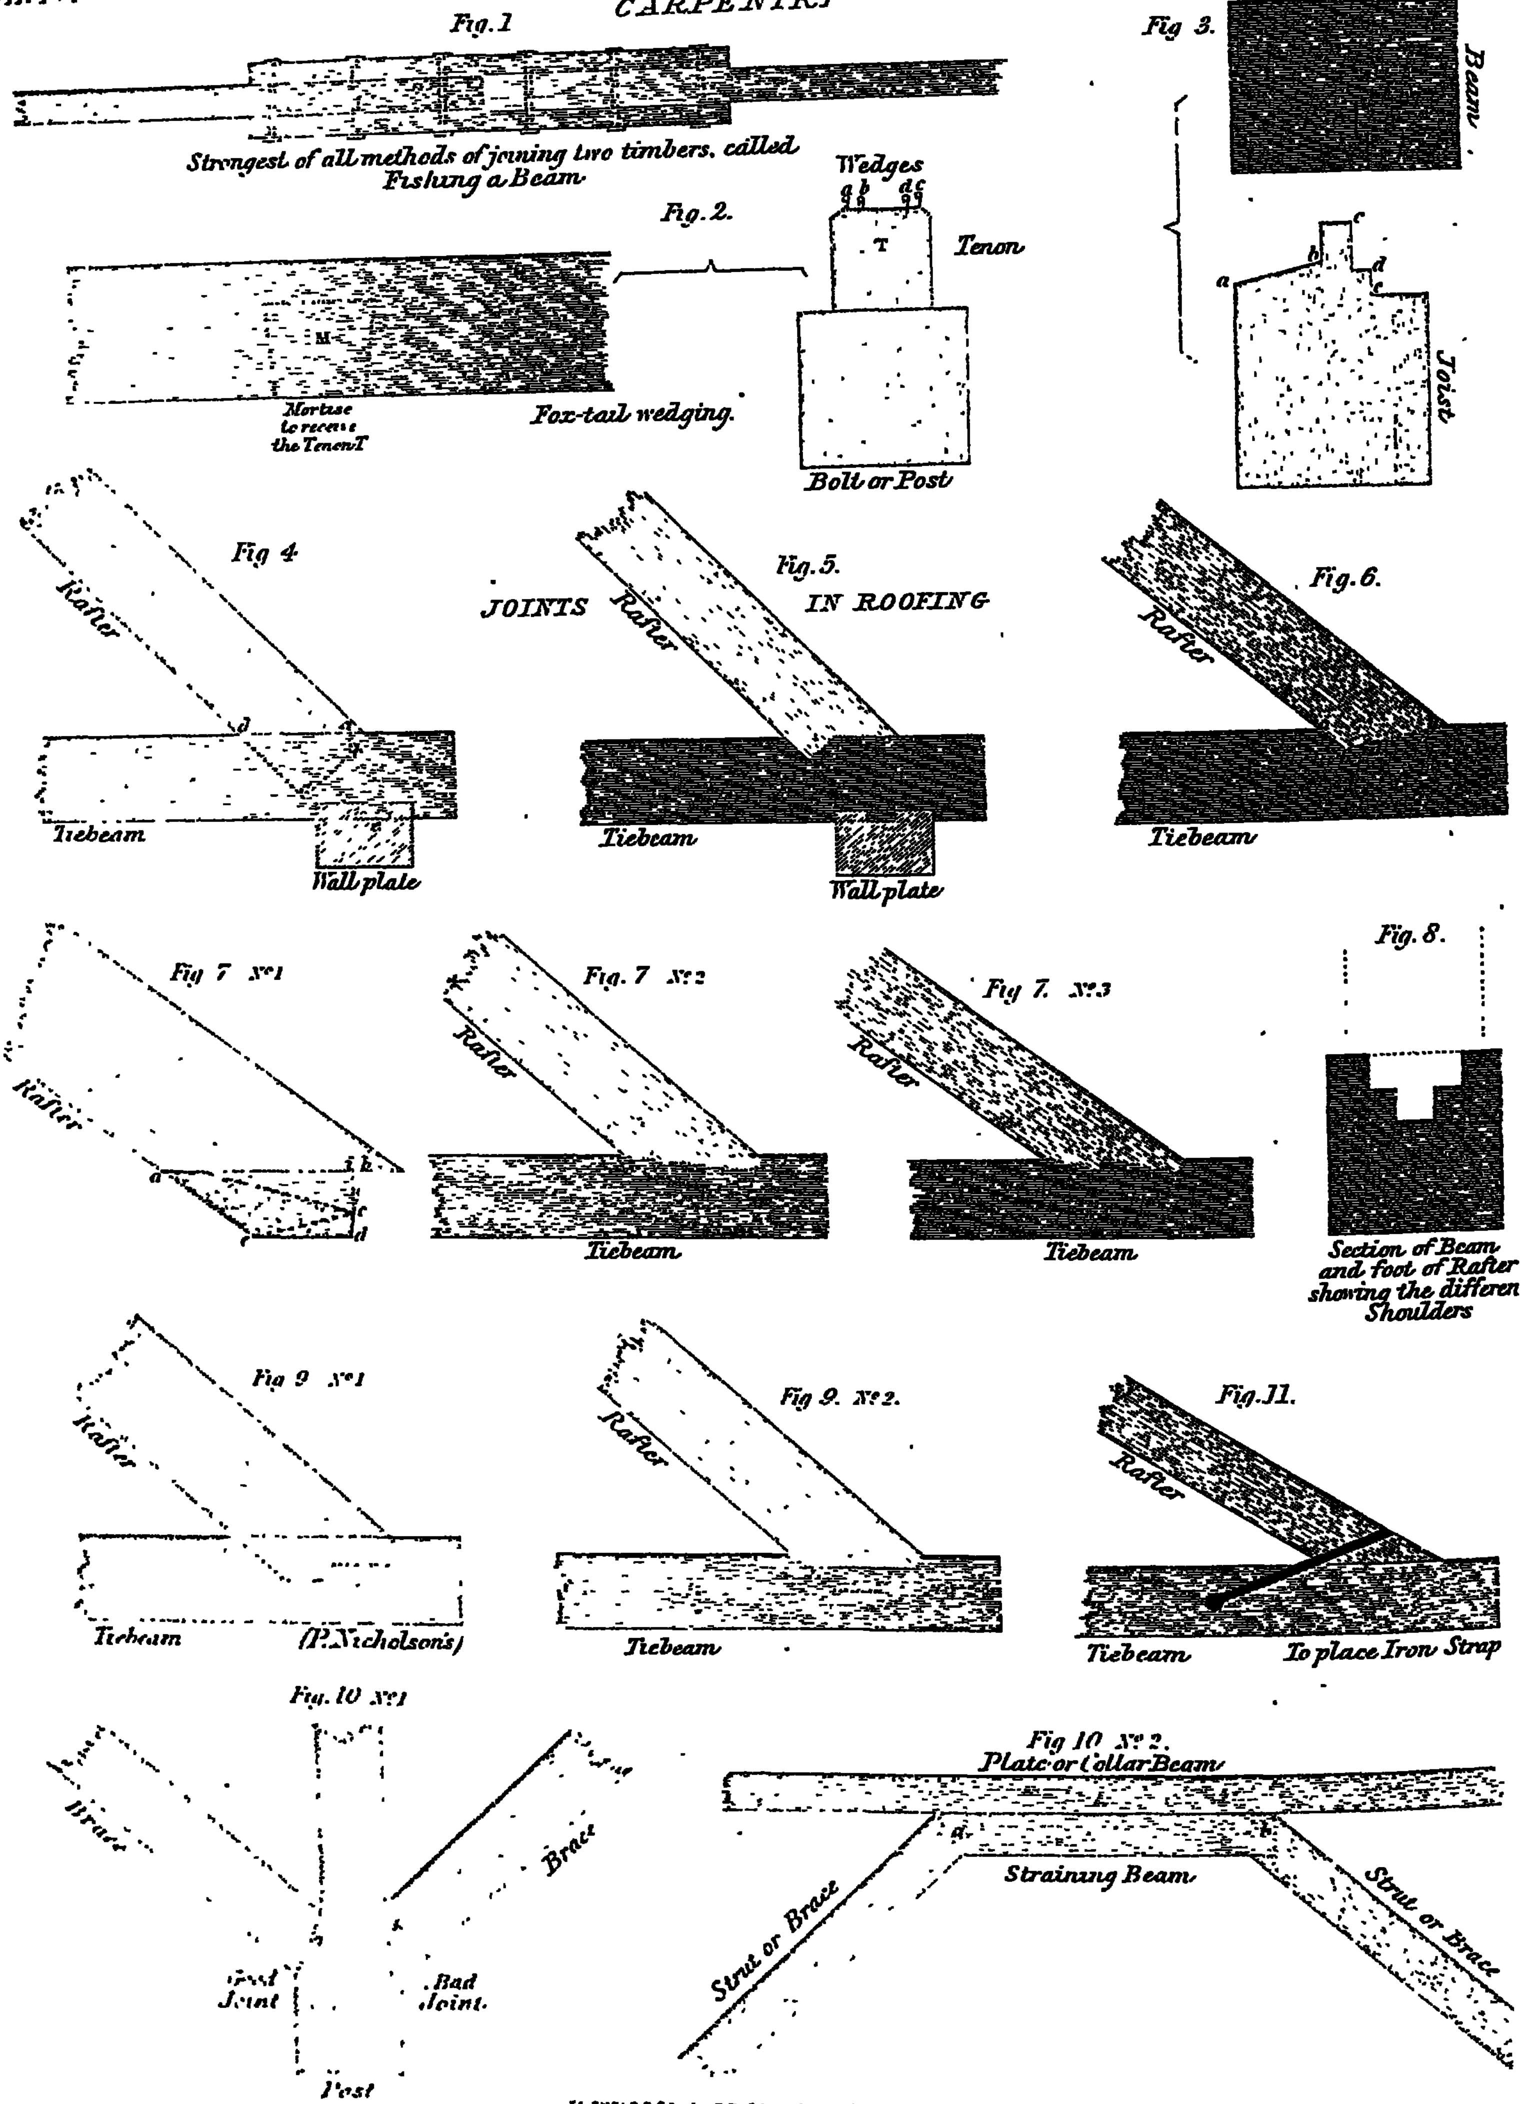
Scarfing. The most general reason for piecing a beam is to increase its length. This is frequently necessary, in order to procure tie-beams for very wide roofs. Two pieces must be scarfed together. Numberless are the modes of doing this, and almost every master carpenter has his favourite nostrum. Some of them are very ingenious; but here, as in other cases, the most simple are commonly the strongest. We do not imagine that any, the most ingenious, is equally strong with a tie consisting of two pieces of the same scantling laid over each other for a certain length, and firmly bolted together. We acknowledge that this will appear an artless and clumsy tie-beam, but it will be stronger than any that is more artificially made up of the same thickness of timber. The next simplest and most obvious scarfing is that represented in Plate XXII., fig. 8, Nos. 1 and 2. If considered merely as two pieces of wood joined, it is plain that, as a tie, it has but half the strength of an entire piece, supposing that the bolts (which are the only connections) are fast in their holes. No. 2 requires a bolt in the middle of the scarf to give it that strength, and in every other part is weaker on one side or the other. If the bolts were sufficiently numerous and sufficiently firm, so as to produce a great degree of adhesion or of friction between the parts, this joint might be made almost as strong as the entire beam, since there is nothing to prevent the co-operation of each side with the other throughout its extent; but much of the strength would be lost if the bolts became loose, even in an inconsiderable degree. But the bolts are very apt to bend by the violent strain, and require to be strengthened by uniting their ends by iron plates,—in which case it is no longer a wooden tie. The form of No. 1 is better adapted to the office of a pillar than No. 2, especially if its ends be formed in the manner shown in the elevation No. 3. By the sally given to the ends, the scarf resists an effort to bend it in that direction. Besides, the form of No. 2 is unsuitable for a post, because the pieces by sliding on each other by the pressure are apt to splinter off the tongue which confines their extremity. Figs. 9 and 10 exhibit the most approved form of a scarf, whether for a tie or for a post. The key represented in the middle is not essentially necessary; the two pieces might simply meet square there. This form, without a key, needs no bolts (although they strengthen it greatly), but, if worked very true and close, and with square abutments, will hold together, and will resist bending in any direction. But the key is a very great improvement, and will force the parts together with perfect tightness, but it must not be over driven. The form of fig. 9 is by far the best (it is sometimes said to be tabulated, that is, to render the joints as close as possible, and the juncture more independent of any bolts which might be placed similarly to those in fig. 8, No. 1),—because the triangle of fig. 10 is much more readily splintered off by the strain or by the key than the square wood of fig. 9. It is far preferable for a post, for the reason given in speaking of fig. 8, No. 1 and No. 2. Both may be formed with a sally at the ends equal to the breadth of the key. In this shape fig. 9 is well suited for joining the parts of the long corner posts of spires and other wooden towers. Fig. 9, No. 2 differs from No. 1 only by having three keys; the principle and the longitudinal strength are the same. The long scarf of No. 2, tightened by the three keys, enables it to resist bending much better.

None of these scarfed tie-beams can have more than one third of the strength of an entire piece, unless with the assistance of iron plates; for if the key be made thinner than one-third, it has less than one-third of the fibres to pull by. We are confident, therefore, that when the heads of the bolts are connected by plates, the simple form of fig. 8, No. 1, is stronger than those more ingenious scarfings. It may be strengthened against lateral bending by a little tongue, or by a sally, but cannot have both.

Fishing a beam. The strongest of all methods of piecing a tie-beam would be to set the parts end to end, and grasp them between other pieces on each side, as in Plate XXIII., fig. 1. This the ship-carpenter calls fishing a beam; it is a frequent practice for occasional repairs. Perronet used it for the tie-beams or stretchers by which he connected the opposite feet of

BUILDING

CARPENTRY



a centre, which was yielding to its load, and had pushed aside one of the piers above 4 inches

Where the beams stand square with each other, and the strains are square with the beams and in the plane of the frame, the mortise and tenon is the most perfect junction. A pin is generally put through both in order to keep the pieces united, in opposition to any force which tends to part them. Every carpenter knows how to bore the hole for this pin, so that it shall draw the tenon tight into the mortise, and cause the shoulder to butt close, and make neat work; and he knows the risk of tearing out the bit of the tenon beyond the pin, if he draw it too much. We may just observe, that square holes and pins are much preferable to round ones for this purpose, bringing more of the wood into action, with less tendency to split it.

Ship-carpenters have an ingenious method of making long wooden bolts, not passing completely through, which take a very fast hold, though not nicely fitted to their holes, which they must not be, lest they should be crippled in driving. They call it fox-tail wedging. They stick into the point of the bolt T, Plate XXIII., fig 2, thin wedges of hard wood, so as to project a proper distance; when these reach the bottom of the hole by driving the bolt, they split the end of it, and squeeze it hard to the side. This may be practised with advantage in carpentry. If the ends of the mortise are widened inwards, and a thin wedge be put into the end of the tenon, it will have the same effect, and make the joint equal to a dove-tail; but this risks the splitting the piece beyond the shoulder of the tenon, which would be unsightly, and may be avoided by two *very* thin wedges *a* and *c* being struck in near its angles, projecting equally; at a very small distance within these are to be placed two shorter ones *b*, *d*, and more within these if necessary. In driving this tenon, the wedges *a* and *c* will take first, and split off a thin slice, which will easily bend without breaking. The wedges *b*, *d* will act next, and have a similar effect, and the others in succession. The thickness of all the wedges taken together must be equal to the enlargement of the mortise towards the bottom.

When the strain is transverse to the plane of the two beams, great care must be taken by the artist in placing his mortise A mortise in a girder for receiving the tenon of a binding-joist of a floor should be as near the upper side as possible, because the girder becomes concave on that side by the strain. But as this exposes the tenon of the binding-joist to the risk of being torn off, we are obliged to mortise further down. The form in Plate XXIII., fig. 3, generally given to this joint is extremely judicious. The sloping part *a b* gives a very firm support to the additional bearing *e d*, without much weakening of the girder. This form should be copied in every case where the strain has a similar direction

The joint that most of all demands the careful attention of the artist is that which connects the ends of beams, one of which pushes the other very obliquely, putting it into a state of extension. The most familiar instance of this is the foot of a rafter pressing on the tie-beam, and thereby *drawing* it away from the other wall. When the direction is very oblique (in which case the extending strain is the greatest), it is difficult to give the foot of the rafter such a hold of the tie-beam as to bring many of its fibres into the proper action. There would be little difficulty if we could allow the end of the tie-beam to project to a small distance beyond the foot of the rafter; but, indeed, the dimensions which are given to tie-beams for other reasons are always sufficient to give enough of abutment when judiciously employed. Unfortunately, this joint is very liable to fail from the effects of the weather. It is much exposed, and frequently perishes by rot, or becomes so soft and friable that a very small force is sufficient either for pulling the filaments out of the tie-beam, or for crushing them together. We are therefore obliged to secure it with particular attention, and to avail ourselves of every circumstance of construction.

One is naturally disposed to give the rafter a deep hold by a long tenon, but it has been frequently observed in old roofs that such tenons break off. Frequently they are observed to tear up the wood that is above them, and push their way through the end of the tie-beam. This in all probability arises from the first sagging of the roof, by the compression of the rafters and of the head of the king-post. The head of the rafter descends, and the angle with the tie-beam is diminished by the rafter revolving round its step in the tie-beam. By this motion the heel or inner angle of the rafter becomes a fulcrum to a very long and powerful lever much loaded. The tenon is the other arm, very short; and being still fresh, it is therefore very powerful. It therefore forces up the wood that is above it, tearing it out from between the cheeks of the mortise, and then pushes it along. Carpenters have therefore given up long tenons, and give to the toe of the tenon a shape which abuts firmly, in the direction of the thrust, on the solid bottom of the mortise, which is well supported on the under side by the wall-plate. This form, represented in Plate XXIII., fig. 4, has no tendency to tear up the end of the mortise. The tenon has a small portion *a b* cut perpendicular to the surface of the tie-beam, and the rest *b c* is perpendicular to the rafter.

But if the tenon is not sufficiently strong and it is not so strong as the rafter, which is thought not to be stronger than is necessary), it will be crushed, and then the rafter will slide out along the surface of the beam. It is therefore necessary to call in the assistance of the whole rafter. It is in this distribution of the strain among the various abutting parts that the varieties of joints and their merits chiefly consist. We can only mention a few here that have met with most general approval.

The aim in fig. 5, Plate XXIII., is to make the abutments exactly perpendicular to the thrusts. The action is the same as against the joggle on the head or foot of a king-post. This is a very effectual joint; it is not, however, much practised. It is said that the sloping seam at the shoulder lodges water; but the great on seems to be a secret notion that it weakens the tie- eam. Fig. 6 exhibits a form that is more general, but certainly worse. The shoulder-joint is sometimes formed like the dotted line *abcdcfg* of fig. 6. This is much more agreeable to the true principle, and would be a very perfect method, were it not that the intervals *b d* and *d f* are so short that the little wooden triangles *b e d*, *d c f* will be easily pushed off their bases *b d*, *d f*. Fig. 7, No. 1, seems to have the most general approbation, but we fail to perceive its peculiar merits. It is the joint recommended by Price, and copied into books of carpentry as the *true joint* for a rafter foot. The visible shoulder-joint is flush with the upper surface of the tie-beam. The angle of the tenon at the tie nearly bisects the obtuse angle formed by the rafter and the beam, and is therefore somewhat oblique to the thrust. The inner shoulder *a c* is nearly perpendicular to *b d*. The lower angle of the tenon is cut off horizontally as at *e d*. Fig. 8 is a section of the beam and rafter foot, showing the different shoulders. Fig. 7, No. 2, is a simpler, and in our opinion a preferable joint. We observe it practised by the most eminent carpenters for all oblique thrusts; but it surely employs less of the cohesion of the tie-beam than might be used without weakening it, at least when it is supported on the other side by the wall-plate. Fig. 7, No. 3, is also much practised by the best carpenters. Fig. 9, No. 1, is proposed by Mr Nicholson as preferable to fig. 7. No. 3,

Various forms of joints.

:cause the abutment of the inner part is better supported. his is certainly the case, but it supposes the whole rafter go to the bottom of the socket, and the beam to be iicker than the rafter. Some may think that this will eaken the beam too much, when it is no broader than the fter is thick; in which case they think that it requires deeper socket than Nicholson has given it. Perhaps the lvantages of Nicholson's construction may be had by a int like fig. 9, No. 2.

Whatever is the form of these butting joints, great care ould be taken that all parts bear alike; and the artist ill attend to the magnitude of the different surfaces. In e general compression the greater surfaces will be less mpressed, and the smaller will therefore change most. hen all has settled, every part should be equally close. :cause great logs are moved with difficulty, it is very oublesome to try the joint frequently to see how the rts fit; therefore we must expect less accuracy in the terior parts. This should make us prefer those joints iose efficacy depends chiefly on the visible joint. It pears from all that has been said on this subject, that a ry small part of the cohesion of the tie-beam is sufficient r withstanding the horizontal thrust of a roof, even ough very low pitched. If, therefore, no other use is ade of the tie-beam, one much slenderer may be used, id blocks may be firmly fixed to the ends, on which the fters might abut, as they do on the joggles on the head id foot of a king-post. A tie-beam may have to carry floor or ceiling (sometimes the workshops and store-rooms a theatre), and therefore requires a great scantling, but equently beams have little to do, and contain an unneces- ry quantity of timber. It is therefore of importance to certain the most perfect manner of executing such a nt, and we have directed the attention to the principles at are really concerned in the effect. In all hazardous ses the carpenter calls in the assistance of iron straps; d they are frequently necessary, even in roofs, not- thstanding this superabundant strength of the tie-beam. it this is generally owing to bad construction of the ooden joint, or to the failure of it by time.

There needs but little to be said of the joints at a joggle orked out of solid timber; they are not near so diffi- lt as the last. When the size of a log will allow the ggle to receive the whole breadth of the abutting brace, ought certainly to be made with a square shoulder; , which is still better, an arch of a circle having the other d of the brace for its centre. Indeed, this in general ll not sensibly differ from a straight line perpendicular the brace. By this circular form the settling of the of makes no change in the abutment; but when ere is not sufficient stuff for this, we must avoid vel joints at the shoulders, because these always tend to ake the brace slide off. The brace in Plate XXIII., ;. 10, No. 1, must not be joined as at b, but as at a, or some equivalent manner.

When the very oblique action of one side of a frame of rpentry does not extend, but compresses, the piece on hich it abuts, there is no difficulty in the joint. Indeed joining is unnecessary, and it is enough that the pieces but on each other; and we have only to take care that he mutual pressure be equally borne by all the parts, and hat it do not produce lateral pressures, which may cause ne of the pieces to slide on the butting joint. A very light mortise and tenon is sufficient at the joggle of a ing-post with a rafter or straining beam. It is best, in eneral, to make the butting plain, bisecting the angle ormed by the sides, or else perpendicular to one of the ieces. In fig. 10, No. 2, where the straining beam a b annot slip away from the pressure, the joint a is preferable o b, or indeed to any uneven joint, which never fails to produce very unequal pressures on the different parts, by which some are crippled, others are splintered off, &c.

When it is necessary to employ iron straps for strength- ening a joint, considerable attention is necessary that we may place them properly. The first thing to be determined is the direction of the strain. This must be resolved into a strain parallel to each piece, and another perpendicular to it; and then the strap which is to be made fast to any of the pieces must be so fixed that it shall resist in the direc- tion parallel to the piece. Frequently this cannot be done; but we must come as near to it as we can. We can hardly give any general rules. Fig. 30 shows the nature of the strap or stirrup by which the king-post carries the tie-beam. The strap that we observe most generally ill placed is that which connects the foot of the rafter with the beam. It only binds down the rafter, and does not act against its horizontal thrust. It should be placed farther back on the beam, with a bolt through it, which will allow it to turn round. It should embrace the rafter almost horizontally near the foot, and should be notched square with the back of the rafter. It is represented in fig. 11, Plate XXIII. By moving round the eye-bolt, it follows the rafter, and cannot pinch and cripple it, which it always does in its ordinary form. We are of opinion that straps which have eye-bolts in the very angles, and allow all motion round them, are of all the most perfect. A branched strap, such as may at once bind the king-post and the two braces which butt on its foot, will be more serviceable if it have a joint. When a roof warps, those branched straps fre- quently break the tenons, by affording a fulcrum in one of their bolts. An attentive and judicious artist will consider how the beams will act on such occasions, and will avoid giving rise to these great strains by levers. In the fore- going reasoning upon the direction of straps, regard has been had especially to the economizing of their immediate strength; but it may happen that the principal purpose of the strap will be answered by its pressing the rafter firmly upon the beam, and this effect may be produced by a certain deviation from the horizontal position, with but little diminution of the strength of the strap,—a deviation which has also the advantage of allowing the strap to embrace the whole of the beam, without weakening it by driving a bolt through it. We must not, however, run the risk of crippling the end of the beam. A skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art, and subject to imperfections in workmanship which he cannot discern or amend. We must refer the reader to Nicholson's *Carpenter and Joiner's Assistant* for a more particular account of the various forms of stirrups, screwed rods, and other iron-work, for carrying tie-beams, &c.

Placing straps.

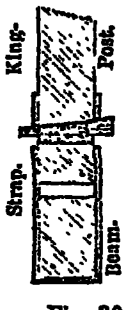


Fig. 30.

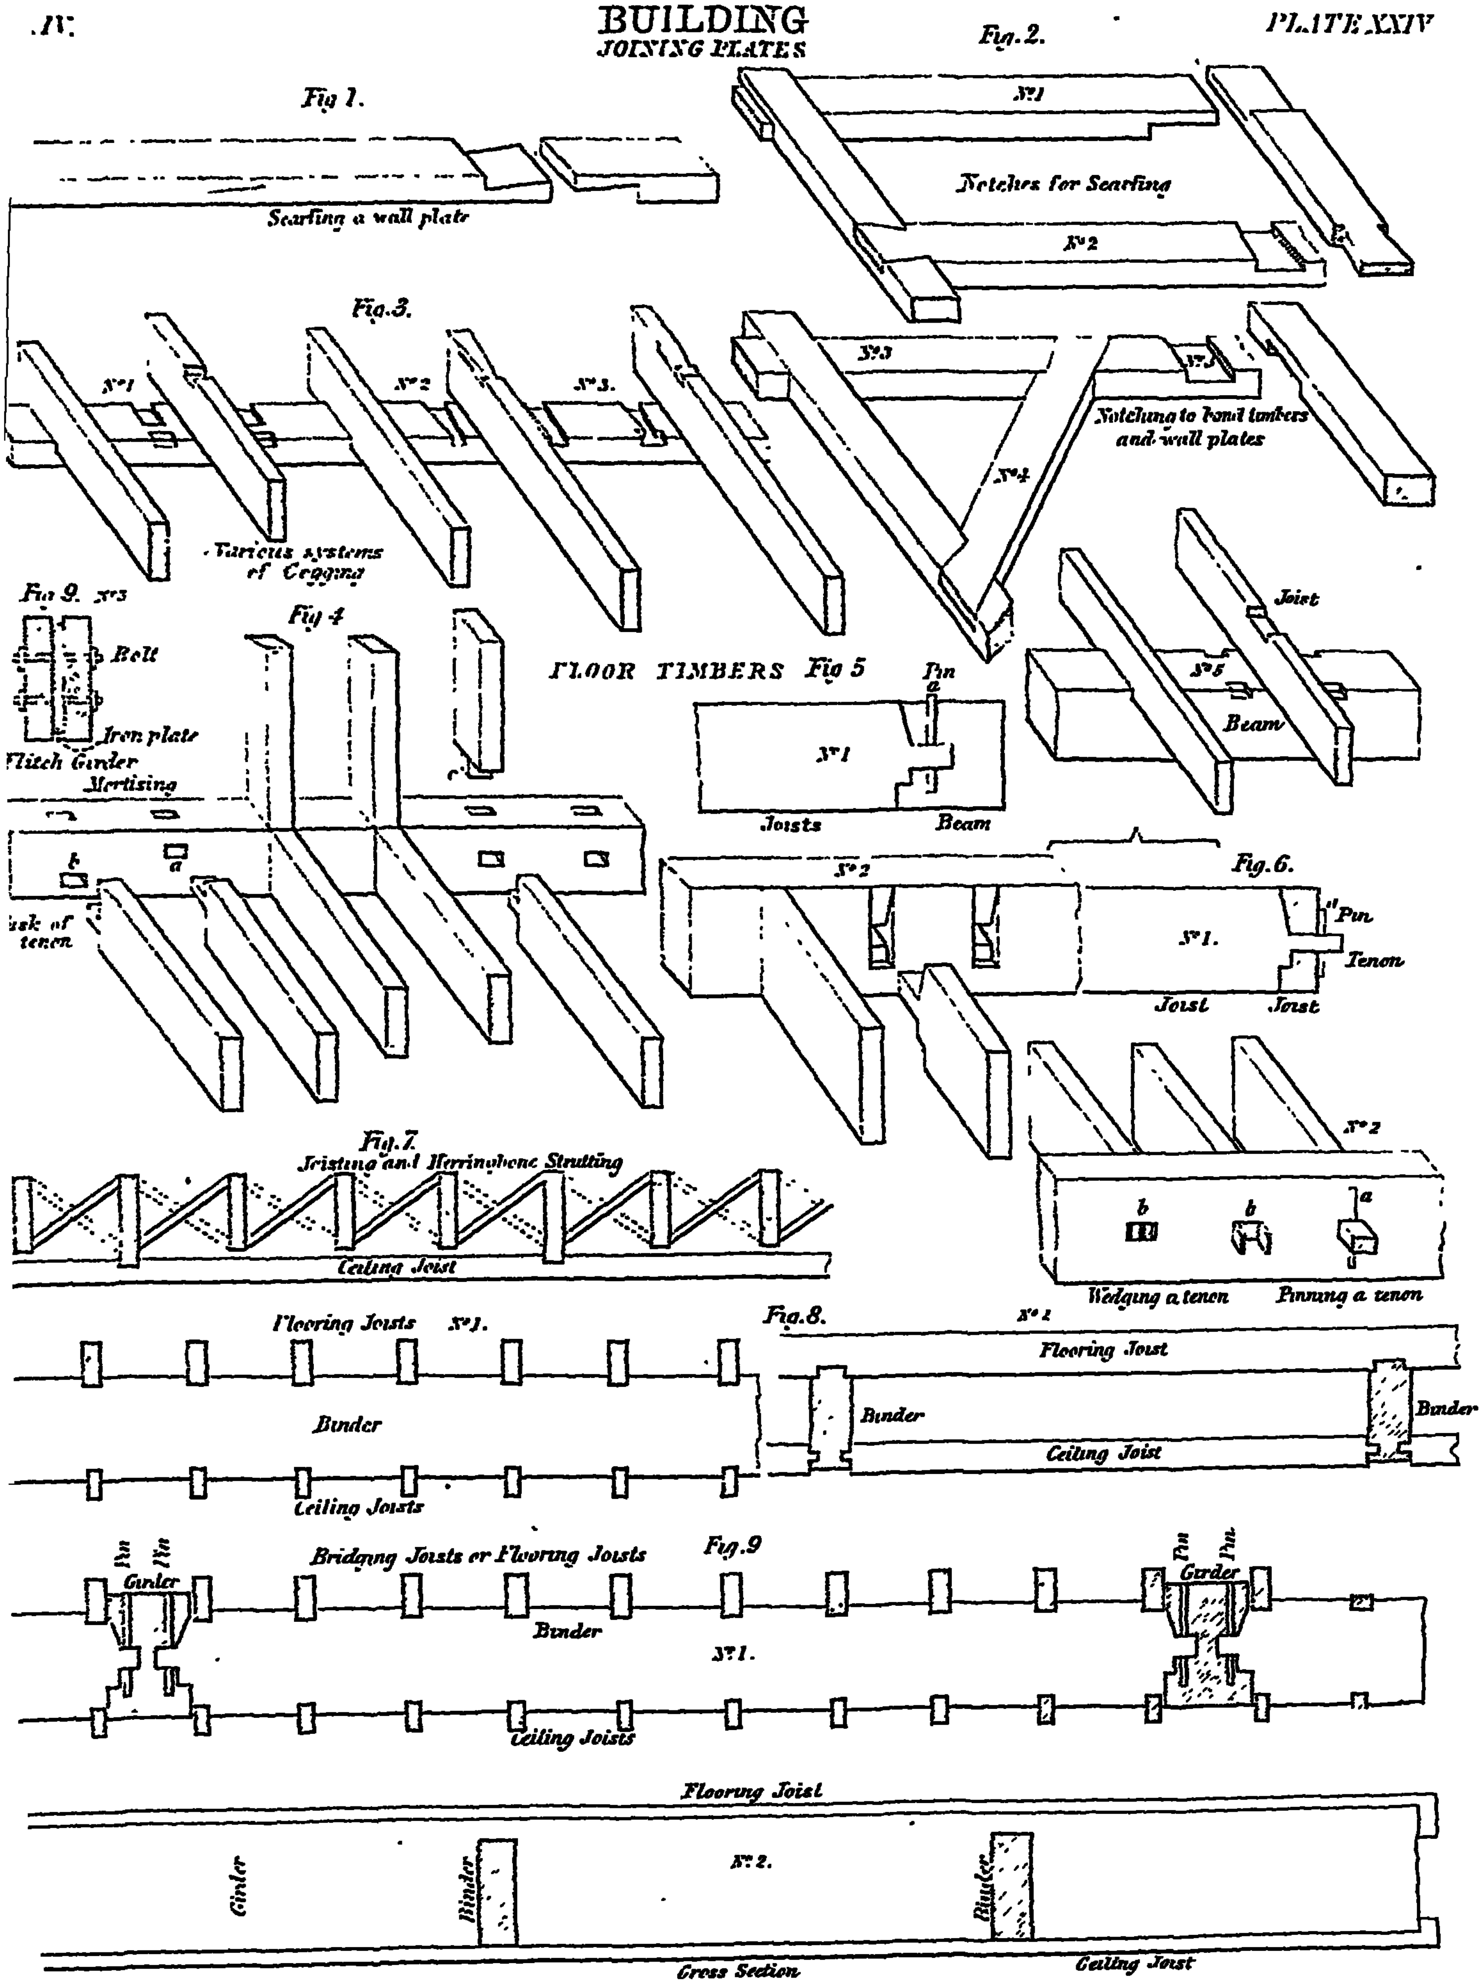
The diagrams of Plate XXIV. will illustrate the use of the before-described joints on a smaller scale in the further operations of the carpenter's work.

Ordinary scarfing is the cutting away equally from the ends, but on the opposite sides, of two pieces of timber, for the purpose of tying or connecting them lengthwise, and is done to wall-plates and bond-timber. The usual mode is by cutting about three-fifths through each piece on the upper face of the one and the under face of the other, about 6 or 8 inches from the end, as in fig. 1, Plate XXIV., transversely, making what is technically termed a *calf* or *kerf*, and longitu- dinally from the end, from two-fifths down on the same side, so that the pieces lap together with a sort of half dovetail. The heavy supervening weight of the wall and joists renders it impossible that they should be drawn apart without tear- ing the fibres asunder or lifting the weight. Nevertheless

JOINING PLATES



7e 480

hese joints are generally spiked, and it is always required that they be made to fall in or under a pier. Notching is either square or dovetailed; it is used in connecting the ends of wall-plates and bond-timber at the angles, in letting joists down on beams or binders, purlines on principal rafters, &c. Nos. 1, 2, 3, 4, and 5, fig. 2, show varieties of notches applied as we have described No. 1 is a simple square notch; No. 2, a dovetailed notch. No. 3 is the notch most commonly used; it is similar to No. 1, but that the ends are allowed to run on so that the one piece grasps the other, and each forms a cog to the other. No. 4 is an oblique-angled, dovetailed notch; and No. 5 shows how joists are notched or let down on beams and binders, and purlines on principal rafters. A notch is cut into the under edge of the joist or purline an inch or an inch and a half in depth, and considerably shorter than the beam, binder, or rafter is in thickness. Notches are also cut down on the upper angles of the bearing pieces, as long as the rider is thick, as deep as the notch before described of the latter is, and so far in as to leave a thickness on its own edge equal to the length of the notch in the riding joist or purline. In the diagram one joist is indicated in its place let down in the notch, and another indicates the notch in its own edge, and leaves exposed the notches in the binder. Cogging, or corking, as it is vulgarly termed, is the last-mentioned species of notch extended on one side, and leaving a narrow tooth or cog alone in the bearing-piece flush with its upper face, No. 1, fig. 3. It is used principally in tailing joists and beams on wall-plates and templets, and the cog is here made narrower, because the end of the joist or rider coming immediately beyond the plate, that part which forms the shoulder of the notch would be liable, on being strained, to be chipped off or torn away, if it were not kept as long as possible; and it is not of so much importance to guard against weakening a wall-plate which is supported along its whole length, as a beam, binder, or principal rafter, which rests on distant points alone. No. 2 of the same figure shows another mode of tailing on joists and beams by a dovetail notch, which, to distinguish it from the flat notches, Nos. 2 and 4, fig. 2, is called corking, or cogging also, though the operation certainly is not cogging. This is a good mode if the timber be so well seasoned as not to be likely to shrink more; but it would be improved by allowing the rider to take a bearing in a notch like that to No. 1 before the dovetail commenced, as at No. 3, for in the ordinary mode it is weakened in a point of great importance. Whatever notches and cogs for beams and joists are required in wall-plates and templets, should be made before they are set on or in a wall; for, as they are always bedded in mortar, anything that may break the set must be avoided. A cog-hold is best obtained through the agency of a chair of cast-iron, which should, however, be itself cogged or joggled to a stone templet laid in the wall under it, and be capped or covered by another broad flat stone, as an inverted templet, with a joggle from the chair running up into it.

Tenoning implies mortising also as a matter of course. They are the names of the two operations necessary to one result,—that of producing a connection between two pieces by inserting part of the end of one into a hole of similar size cut in the side or face of the other. A tenon is formed by cutting in on each side or edge of a piece of timber, near its end, transversely, to a certain depth, or rather, leaving a certain part of the breadth or depth uncut, and then cutting in longitudinally from the ends as far from each edge as the transverse cuts have been made in depth, thus removing two square prisms and leaving a third undivided. This is the tenon. An excavation in the side of a piece of timber, of a certain depth, in the direction of its thickness, parallel to its edges, and bounded lengthwise by lines at right angles to them, is a mortise. Tenons and mortises are made of exactly corresponding size, and are most frequently at equal distances from one or the other side or edge of the two pieces to be conjoined; and for the most part, too, every angle formed in the process of tenoning, both internal and external, is a right angle. Tenons are called joggles in some situations, when they are not intended to be borne upon, and their use is merely to keep the piece of timber to which they belong steadily in its place, without being liable to slight accidents from lateral pressure or violence. In combining timbers by means of mortises and tenons, to produce as great a degree of strength as possible, it must be obvious that the object to be kept in view is to maintain the end or tenon of the one as large and efficient as it may be, and weaken the other as little as possible in forming the mortise. For the efficiency of the mortised piece in a horizontal bearing, it is clear that as much of its thickness should be below the mortise as possible, as at *a*, fig. 4; for if it be put low, as at *b*, the superincumbent weight on the tenon would more readily split or rend it in the direction of the grain, as indicated; but the case is inverted with the tenoned pieces. With the mortise at *a* the tenon could only have the efficacy of so much of the piece to which it belongs as there is of it above its under surface, which is a very small part of its depth; whereas with the tenon at *b* it would command the power of the greatest part of the depth. To guard as much as possible against the danger of too great a mortise and too small a tenon on one side and the other, and to obviate the difficulty arising from the efficiency of one or the other of the two pieces being affected by putting the tenon too high or too low, a compound, called a tusk tenon, is used for almost all horizontal bearings of any importance, especially to joists and binders, to trimmers, beams, girders, bressummers, &c. The body of the tenon in this is a little above the middle of the end, and it runs out 2, 3, or 4 inches, or more, as the case may require. Below it the tusk protrudes, and above it the shoulder is cut down at an obtuse angle with the horizontal line, giving the strength of the whole depth of the timber above the under tusk to the tenon, and giving it a bearing in a shallow mortise, whilst a greater depth of the mortised piece than the tusk rests on receives the body of the tenon, and so protects its comparatively narrow margin from undue pressure. The diagram No. 1, fig. 5, shows the tusk tenon, with the section of a beam into which it is mortised, and No. 2 indicates perspectively the appearance of the mortise in front. Pinning is the insertion of nearly cylindrical pieces of wood or iron through a tenon, to detain it in the mortise, or prevent it from being drawn out by any ordinary force. For this purpose the pin is inserted either in the body, or beyond the thickness, of the mortised piece, as indicated at *a*, fig. 5, or at *a*, fig. 6. Wedging (see *b*, *b*, No. 2, fig. 25) is the insertion of triangular prisms, whose converging sides are under an extremely acute angle, into or beside the end of a tenon, to make it fill the mortise so completely, or bind it so tightly, that it cannot be easily withdrawn. The wedging of tenons also assists in restoring to the mortised piece of timber much of the strength it had lost by the excision of so much of its mass, which indeed the tenon itself does if it fit closely in every direction; but the assistance of the wedge renders the restoration more perfect than the tenon could secure of itself, by compressing the fibres of both, longitudinally to those of the one, and transversely to those of the other, thus removing the tendency of the mortised piece to yield in any degree in the weakened part, though it cannot make up the loss in its tenacity occasioned by the scission of its fibres.

Pinning.

Wedging.

In scarfing, cogging, and notching, the shoulders are

these joints are generally spiked, and it is always required that they be made to fall in or under a pier. Notching is either square or dovetailed; it is used in connecting the ends of wall-plates and bond-timber at the angles, in letting joists down on beams or binders, purlines on principal rafters, &c. Nos. 1, 2, 3, 4, and 5, fig. 2, show varieties of notches applied as we have described No. 1 is a simple square notch; No. 2, a dovetailed notch. No. 3 is the notch most commonly used; it is similar to No. 1, but that the ends are allowed to run on so that the one piece grasps the other, and each forms a cog to the other. No. 4 is an oblique-angled, dovetailed notch; and No. 5 shows how joists are notched or let down on beams and binders, and purlines on principal rafters. A notch is cut into the under edge of the joist or purline an inch or an inch and a half in depth, and considerably shorter than the beam, binder, or rafter is in thickness. Notches are also cut down on the upper angles of the bearing pieces, as long as the rider is thick, as deep as the notch before described of the latter is, and so far in as to leave a thickness on its own edge equal to the length of the notch in the riding joist or purline. In the diagram one joist is indicated in its place let down in the notch, and another indicates the notch in its own edge, and leaves exposed the notches in the binder. Cogging, or corking, as it is vulgarly termed, is the last-mentioned species of notch extended on one side, and leaving a narrow tooth or cog alone in the bearing-piece flush with its upper face, No. 1, fig. 3. It is used principally in tailing joists and beams on wall-plates and templets, and the cog is here made narrower, because the end of the joist or rider coming immediately beyond the plate, that part which forms the shoulder of the notch would be liable, on being strained, to be chipped off or torn away, if it were not kept as long as possible; and it is not of so much importance to guard against weakening a wall-plate which is supported along its whole length, as a beam, binder, or principal rafter, which rests on distant points alone. No. 2 of the same figure shows another mode of tailing on joists and beams by a dovetail notch, which, to distinguish it from the flat notches, Nos. 2 and 4, fig. 2, is called corking, or cogging also, though the operation certainly is not cogging. This is a good mode if the timber be so well seasoned as not to be likely to shrink more; but it would be improved by allowing the rider to take a bearing in a notch like that to No. 1 before the dovetail commenced, as at No. 3, for in the ordinary mode it is weakened in a point of great importance. Whatever notches and cogs for beams and joists are required in wall-plates and templets, should be made before they are set on or in a wall; for, as they are always bedded in mortar, anything that may break the set must be avoided. A cog-hold is best obtained through the agency of a chair of cast-iron, which should, however, be itself cogged or joggled to a stone templet laid in the wall under it, and be capped or covered by another broad flat stone, as an inverted templet, with a joggle from the chair running up into it.

Tenoning implies mortising also as a matter of course. They are the names of the two operations necessary to one result,—that of producing a connection between two pieces by inserting part of the end of one into a hole of similar size cut in the side or face of the other. A tenon is formed by cutting in on each side or edge of a piece of timber, near its end, transversely, to a certain depth, or rather, leaving a certain part of the breadth or depth uncut, and then cutting in longitudinally from the ends as far from each edge as the transverse cuts have been made in depth, thus removing two square prisms and leaving a third undivided. This is the tenon. An excavation in the side of a piece of timber, of a certain depth, in the direction of its thickness, parallel to its edges, and bounded lengthwise by lines at right angles to them, is a mortise. Tenons and mortises are made of exactly corresponding size, and are most frequently at equal distances from one or the other side or edge of the two pieces to be conjoined; and for the most part, too, every angle formed in the process of tenoning, both internal and external, is a right angle. Tenons are called joggles in some situations, when they are not intended to be borne upon, and their use is merely to keep the piece of timber to which they belong steadily in its place, without being liable to slight accidents from lateral pressure or violence. In combining timbers by means of mortises and tenons, to produce as great a degree of strength as possible, it must be obvious that the object to be kept in view is to maintain the end or tenon of the one as large and efficient as it may be, and weaken the other as little as possible in forming the mortise. For the efficiency of the mortised piece in a horizontal bearing, it is clear that as much of its thickness should be below the mortise as possible, as at *a*, fig. 4; for if it be put low, as at *b*, the superincumbent weight on the tenon would more readily split or rend it in the direction of the grain, as indicated; but the case is inverted with the tenoned pieces. With the mortise at *a* the tenon could only have the efficacy of so much of the piece to which it belongs as there is of it above its under surface, which is a very small part of its depth; whereas with the tenon at *b* it would command the power of the greatest part of the depth. To guard as much as possible against the danger of too great a mortise and too small a tenon on one side and the other, and to obviate the difficulty arising from the efficiency of one or the other of the two pieces being affected by putting the tenon too high or too low, a compound, called a tusk tenon, is used for almost all horizontal bearings of any importance, especially to joists and binders, to trimmers, beams, girders, bressummers, &c. The body of the tenon in this is a little above the middle of the end, and it runs out 2, 3, or 4 inches, or more, as the case may require. Below it the tusk protrudes, and above it the shoulder is cut down at an obtuse angle with the horizontal line, giving the strength of the whole depth of the timber above the under tusk to the tenon, and giving it a bearing in a shallow mortise, whilst a greater depth of the mortised piece than the tusk rests on receives the body of the tenon, and so protects its comparatively narrow margin from undue pressure. The diagram No. 1, fig. 5, shows the tusk tenon, with the section of a beam into which it is mortised, and No. 2 indicates perspectively the appearance of the mortise in front. Pinning is the insertion of nearly cylindrical pieces of wood or iron through a tenon, to detain it in the mortise, or prevent it from being drawn out by any ordinary force. For this purpose the pin is inserted either in the body, or beyond the thickness, of the mortised piece, as indicated at *a*, fig. 5, or at *a*, fig. 6. Wedging (see *b*, *b*, No. 2, fig. 25) is the insertion of triangular prisms, whose converging sides are under an extremely acute angle, into or beside the end of a tenon, to make it fill the mortise so completely, or bind it so tightly, that it cannot be easily withdrawn. The wedging of tenons also assists in restoring to the mortised piece of timber much of the strength it had lost by the excision of so much of its mass, which indeed the tenon itself does if it fit closely in every direction; but the assistance of the wedge renders the restoration more perfect than the tenon could secure of itself, by compressing the fibres of both, longitudinally to those of the one, and transversely to those of the other, thus removing the tendency of the mortised piece to yield in any degree in the weakened part, though it cannot make up the loss in its tenacity occasioned by the scission of its fibres.

Pinning.

Wedging.

In scarfing, cogging, and notching, the shoulders are

always cut in with the saw; but the cheek is for the most part struck out with the mallet and chisel, or adze, as may be most convenient. Tenons should be made entirely with the saw. Mortises are generally bored at the ends with an auger whose diameter equals their thickness; the intervening part is taken out with a wide chisel, cutting in the direction of the fibre; and the ends are squared down with a chisel whose breadth just equals the thickness of the mortise. Wood pins must be rent to insure the equal tenacity of their whole mass. Wedges are cut with the saw, but straight-grained stuff is always preferred for them.

Bond-timbers and wall-plates should be carefully notched together at every angle and return, and scarfed at every longitudinal joint. The scarf shown at fig. 1, Plate XXIV., is sufficient; and the notch at No. 3, fig. 2, may be preferred where notching is required; neither pinning nor nailing, however, can be of great use to either the notch or the scarf. Bond-timbers are passed along and through all openings, and are not cut out until such openings are to be permanently occupied, that is, by windows with their sash-frames, &c., because they assist in preventing irregular settlements, by helping to carry the weight of a heavy part along the substruction generally, instead of allowing it to press unduly upon the part immediately under it.

It is the duty of the carpenter to supply the bricklayer or mason with wood bricks in sufficient quantity, and to direct him where they should be placed to receive the joiner's fittings, or the battening, which the carpenter himself may have to put up for the plasterer.

...tres for ...es. The carpenter makes and fixes or sets centres of all kinds, whether for single arches or niches, or even in bridge construction. Large centres are framed in distinct ribs, and are connected by horizontal ties; whilst small ones are made of mere boards cut to the required sweep, nailed together, and connected by battens notched into or nailed on their edges. Precision and stability are nevertheless equally and absolutely necessary, as it is impossible for an arch to be turned or set correctly on an incorrect or unstable centre.

...rs. Descriptions of various sorts of flooring are noticed in the earlier part of this article as for fireproof structures; and also under *Brickwork* and *Mason-work*. The timbers or framework of ordinary house and warehouse floors is called naked flooring, and it is distinguished as single, double, and framed. Of these the first, under ordinary circumstances, is the strongest.

...le ...ring. Single flooring (Plate XXV. figs. 1, 2) consists of one row or tier of joists alone, bearing from one wall or partition to another, without any intermediate support, and receiving the flooring boards on the upper surface or edges of the joists, and the ceiling, if there be one, on the lower. Joists in single floors should never be less than 2 inches in thickness, because of their liability to be split by the brads or nails of the boards if they are thinner; and they should never be much more, because of the keying of the ceiling, which is injuriously affected by great thickness of the joists. Twelve inches from joist to joist is the distance generally allowed; that dimension, however, from centre to centre of the joists would be better. Strength to almost any extent may be given by adding to the depth of the joists, and diminishing the distance between them; and they may be made firm, and be prevented from buckling or twisting, by putting struts between them. The struts are short pieces of batten, fig. 31, which should not be less than an inch, and need not be more than an inch and a half thick, and 3 or 4 inches wide, placed diagonally between the joists, to which they are nailed, in a double series, or crossing, as indicated by the full and dotted lines in Plate XXIV. fig. 7; and they should be made to range in a right line, that none of their effect may be lost; and these ranges

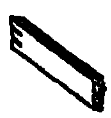


FIG. 31.—Strut.

or rows should be repeated at intervals not exceeding 5 or 6 feet. The struts should be cut at the ends with exactly the same inclination or bevel, to fit closely. Great care should be taken, too, not to split the struts in nailing; but the trouble of boring with a gimlet is saved by making a slight nick or incision with a wide-set saw for each nail, of which there should not be less than two at each end; and the nails used should be clasp-nails. If the struts were notched into the joists, as in fig. 32, it would add very materially to their efficiency, but perhaps not in proportion to the additional labour it would involve. This strutting should be done to single flooring under any circumstances, as it adds materially to its firmness and indeed to its strength, by making the joists transmit any stress or pressure from one to another.

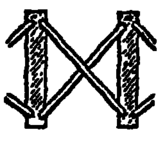

FIG. 32.—Herring-bone Strutting.

The efficiency of single flooring is materially affected by the necessity which constantly occurs in practice of trimming round fire-places and flues, and across vacuities. Trimming is a mode of supporting the end of a joist by tenoning it into a piece of timber crossing it, and called a trimmer, instead of running it on or into the wall which supports the ends of the other joists generally. A trimmer requires for the most part to be carried or supported at one or both of its ends by some of the joists, which are called trimming joists, and are necessarily made stouter than if they had to bear no more than their own share of the stress. Commonly it is found enough to make the trimmers and trimming joists from half an inch to an inch thicker than common joists. In trimming, tusk tenons should be used; and the long tongue or main body of the tenon should run not less than 2 inches through, and be draw-pinned and wedged, moreover, if it do not completely fill the mortise in the direction of the length of the latter. Trimmi...

The principal objection, however, to single flooring is, that sound readily passes through, the attachment of the boards above and of the ceiling below being to the same joists throughout. Another objection, and one already referred to, is the necessity of making the joists so thin, not to injure the ceilings, that they with difficulty receive the flooring brads in their upper edges without splitting. A partial remedy for both these disadvantages is found in a mode sometimes adopted of making every third or fourth joist an inch or an inch and a half deeper than the intervening joists; and to these, ceiling joists are notched and nailed, or nailed alone, as shown in Plate XXIV. fig. 7. This, by diminishing the number of points of contact between the upper and the lower surface, for the ceiling joists must be carefully kept from touching the shallower joists of the floor, is less apt to convey sound from one story to another, and allows conveniently thin joists to be used for the ceiling without affecting those of the floor. Objections to single floors.

Double flooring (see Plate XXIV. fig. 8, Nos. 1 and 2, and Plate XXV. fig. 3) consists of three distinct series of joists, which are called binding, bridging, and ceiling joists. The binders in this are the real support of the floor; they run from wall to wall, and carry the bridging joists above and the ceiling joists below them. Binders need not be less and should not be much more than 6 feet apart, that is, if the bridging or flooring joists are not inordinately weak. The bridging joists form the upper tier, and are notched down on the binders with the notch No. 5, Plate XXIV. fig. 2. The ceiling joists range under the binders, and are notched and nailed as shown at No. 1, fig. 8; but the notch must be taken entirely out of the ceiling joists, for the lower face or edge of the binder may not be wounded by any means or on any account, and, moreover, no good would be gained in any other respect by doing so. When Double flooring.

it is an object to save height in the depth or thickness of this species of floor, the ceiling joists may be tenoned into the binders, instead of being nailed to them; in this case the latter must be chase-mortised on one side, fig. 33, for the convenience of receiving the former when they are themselves set and fixed. A chase is a long wedge-formed groove of the breadth or thickness of the mortise, of which it is indeed an elongation, so that the tenon at one end of the ceiling joist being inserted in the regular mortise in the binder prepared for it, that at the other end is driven along the chase up to its place in the mortise in the next binder. When ceiling joists are thus chase-mortised, their lower or under faces are allowed to come a little below the under face of the binders, and the space across is firred down by slips not wider than the ceiling joists are thick. No. 2, fig. 8, shows a transverse compartment, or bay, of a floor in this manner; but it is not so good a one as the preceding; for, besides the weakening of the binders, by cutting so many mortises and chases in them, it is almost impossible to give the ceiling floor the degree of firmness and consistency it possesses in the other way, besides requiring the firring down on the binders. The same space would be better gained by cutting the bridging joists so much lower down; as they may, with the sort of notch indicated above, be let down fully half their depth without great injury to either bridging joists or binder, for they can always be made to fit tightly or firmly, and very little more labour is involved in notching deeply than slightly.

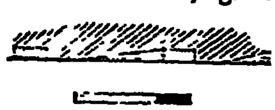

FIG. 33.—Chase Mortise.

Framed flooring. Flooring is said to be framed when girders are used together with binding, bridging, and ceiling joists (see Plate XXIV. fig. 9, Nos. 1 and 2, and Pl te XXV. fig. 4).

Girders. Girders are large beams, in one or more pieces, according to the length required, and the size and strength of which timber can be procured. They are intended for longer bearings than mere binders may be trusted at, and may be strengthened by forming a built beam. The principle of constructing girders of any depth, says Tredgold, in his *Carpentry*, is the same as that of building beams, and when properly conducted they are as strong as any truss can be made of the same depth. The most simple method consists in bolting two pieces together, with keys between to prevent the parts sliding upon each other,—the upper one of hard compact wood, the lower of tough straight grained wood. The joints should be at or near the middle of the depth; the thickness of all the keys added together should be greater than one-third more than the whole depth of the girder; and if they be made of hard wood, the breadth should be about twice the thickness. They may be held together by bolts. Fig. 34 is a good form held by bands, and, if the upper timber be cut so as to be smaller towards the ends, would admit of these hoops being driven on till perfectly

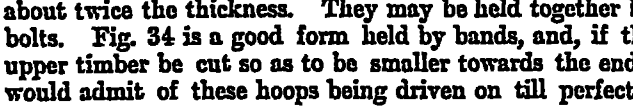

Fig 34

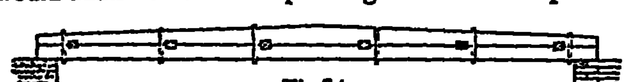

Fig 35

FIGS. 34, 35.—Girders.

tight. In fig. 35 the parts are tabled or indented together instead of being keyed, and a king-bolt is added to tighten the joints. Girders may be further strengthened to almost any extent by trussing; but to be efficient, the height of the truss must always be greater than the depth of the beam itself, and the strength is increased by extending that height as the space or bearing increases. A truss is indeed a wooden arch, whose lateral thrust will of course be greater the smaller the angle subtended by it, and *vice versa*. It has been a commonly received opinion, that a truss less than the depth of a girder adds materially to its strength; but experiments have proved that very little advantage is gained by such a one, even when executed in the best manner, and that, badly executed, the beam or girder is weaker with the truss than without it. In some situations the flooring joists can be raised to a certain height to allow of the head of the truss, which is usually made of iron, being placed at a sufficient height to be truly

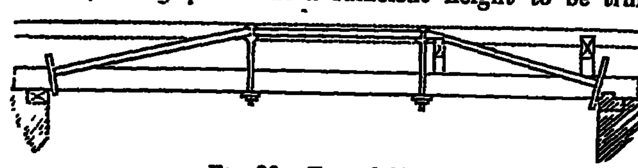

FIG. 36.—Trussed Girder.

efficient. Such is the trussed girder shown in fig. 36, intended for a great length. A common mode of strengthening a beam or bressummer, is to cut the timber in hale longitudinally, whereby any defects in the interior can be seen; then to reverse the pieces, end for end, and bolt them well together. Some additional strength is obtained by putting between the timbers a plate of wrought iron about the depth of the beam and about half an inch in thickness, and then bolting the three together, as in Plate XXIV. fig. 9, No. 3.

Binders are made dependent on the girders by means of double tusk tenons, and on and to them the bridging and ceiling joists are attached as above described. Plate XXIV. fig. 9, No. 1, shows the transverse section of a compartment or bay of a framed floor; No. 2 the same longitudinally of the girder and of the bridging and ceiling joists, and transversely of the binders. Plate XXV. fig. 1, is the plan of a single floor of joists tailing in on wall-plates with two chains of struts, and trimmed to a fire-place. Fig. 2 is a floor similar to fig. 1, with ceiling joists nailed to deeper flooring joists at intervals, as in Plate XXIV. fig. 7. Fig. 3 is the plan of a double floor; and fig. 4 is that of a framed floor of joists, bays of which are shown in section in Plate XXIV. figs. 8, 9. It is to be observed, with reference to the diagram fig. 9, No. 1, that binders ought not to be framed into the girders opposite to one another, as they are here shown to be as a matter of convenience, since the girder is unduly weakened by being mortised on both sides at the same place. Cast-iron shoes render mortising the one forming a tenon upon the other almost unnecessary; and in like manner cast-iron shoes laid into a wall upon stone templets give a good and safe bearing to the girders; but it is not everywhere that cast-iron shoes are attainable, and mortises and tenons may be made anywhere. Plans of floors.

Mediæval flooring. The above descriptions of the three sorts of flooring apply to floors which are to have a ceiling as in house building, or may be left open, as usual in warehouses. But in house building according to the practice of the mediæval period, these timbers would be left exposed. They would all require to be planed smooth, the girders moulded, the binders partly so, and the joists perhaps only stop-chamfered, which is done by cutting the arris of the timber to an angle along its whole length, but stopping short of the ends by a few inches, when it is returned into the arris by a cant. The underside of the joists in a framed floor may be lined with chamfered boarding or formed into panels and ornamented,—a boltel or a set of mouldings forming a frame or cornice all round against the binder. The girders would rest upon stone corbels, either moulded or decorated with foliage or figures, or all three united. Viollet le Duc, in his valuable *Dictionnaire raisonné de l'Architecture*, gives several examples of such a floor,

of one of which we avail ourselves, from a house at Rheims of the 15th century (fig. 37). He gives an example also of

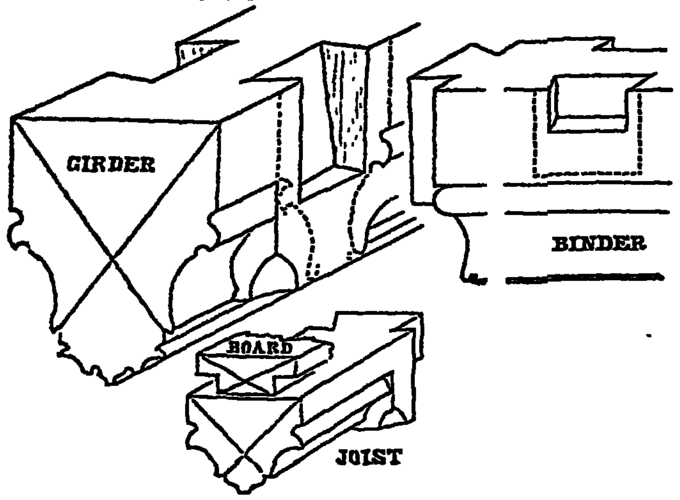

FIG. 37.—Mediæval Flooring.

a floor formed of a girder into which joists are laid formed of square timbers cut in half through the diagonal. These are fixed close together like a succession of v's, thus vvvvv, and boarded over. The top of the angle space formed by two joists is filled up with a small angle fillet presenting a flat surface. The whole effect is unique.

In mediæval carpenters' work it was always the rule only to mould the useful members, and so it was also as regards the carving. Most of the old wood carving is so contrived as to be wrought out of the same plank or thickness as that which is moulded, or else is a separate piece of wood, in a spandril for instance, enclosed within the constructional members. In joining their work, which was of oak, they trusted entirely to tenoning and pinning with stout oak pins.

lars. Although cast-iron columns and stanchions have for some years been preferred to timber posts as supports to girders of warehouse floors, lately the latter have again come into use from their known greater resistance to fire, whereas cast-iron soon succumbs to the great heat and the effects of water upon it. Such posts are usually made of fir or of oak, the dimensions of which vary according to their compound of crushing force and stiffness which is as 25 to 40. The caps to them should be long, so that they may not press into the girders, and if practicable, iron dowels should pass through the girders to catch the bases of the posts in the floor above.

rtitions. Partitions of timber are called quartering partitions, and they are generally framed. Common quartering partitions, which rest on a wall or floor, and have nothing to carry, consist merely of a sill, a head, and common uprights called studs to receive the lath for plastering; these last may be simply joggled or tenoned into the head and sill, as shown in Plate XXIV. fig. 4, *c*, and stiffened by struts or stretching pieces put between them and nailed. When, however, a quartering partition is over a vacuity, or rests only on certain points, and has, moreover, to sustain a weight, a floor perchance, it is framed and trussed with king or queen posts and trussing pieces as to the tie-beam of a roof, and is thence called a trussed partition; and the filling in of common uprights or quarters for the laths is generally performed by joggling them at one end into either head or sill, and nailing them securely to the trussing pieces. In the diagram, Plate XXV. fig. 5, it is supposed that an opening or doorway is to be made in the partition, so that the timbers of the truss are placed around it with queen-posts, and a small internal truss is put over the door-head to prevent it from sagging, and to carry the long part of the partition, which we supposed required to bear a floor, so that the partition acts also, in fact, the part of a trussed girder in the most available form. Fig. 6 presents another method of framing a similar partition. Such partitions should be set up in every story before the beams and joists of the floors are laid, that their horizontal timbers may be notched on to the wall-plates, and that the joists or binders may be notched on to them if occasion require it; but they should be fixed rather below than above the level of the wall-plates, because they are not liable to settle down so much as the walls, though even that will depend in a great degree on the nature of the walling, and its liability to yield. As the whole weight on partitions is supported by the principal posts, their scantlings must be first considered, which should be done in two different ways: first, when the studs are to be filled in with brickwork and rendered thereon, when they are called brick-nog partitions; or secondly, when they are to be lathed and plastered on both sides, or to be wainscoted. Thin partitions of wood only are called framed partitions and are considered in the portion relating to the joiner.

Roofing is another very important branch of the art of carpentry. The most simple form is a shed-roof or lean-to, which is merely obtained by pieces of wood being laid across in the position of an inclined plane to throw off the water. Rectangular buildings are usually covered by a roof in the form of a prism, the vertical section of which is an isosceles triangle. The height of this, or as it is technically called, the pitch of a roof, has varied in different ages, to suit the exigencies of the climate or the taste of the designer. A few examples showing the insertion of the foot of a principal rafter into a tie-beam, the struts into a post, and the heads of struts, are given in Plate XXIII. Roofi

To relate all the specialities which the carpenter may have to do in some particular buildings, as a church, for instance, would far exceed our limits. The mode of executing such things would be the same as already described, the style only making a difference in the result. Pewing or benching—the pulpit and reading-desk, stalls, screenwork, font cover, gallery front, &c.—all depend on the architect's designs. Again, shop fronts are now almost a speciality, together with shop-fittings; and among the minor things in a house are the cupboards, closets, bath, cisterns, kitchen-dresser, plate-rack, dust-bin when not of wholly of brick,—also stable fittings if the improved iron fittings be not used. Centering for arches and for bridges, wharf-walls, spires, turrets, belfries, church bell hangings, gables, are all embraced in carpenter's work, as well as timber houses, the manner of framing which, and the names of the different timbers, will be found described in Le Muet's work (1747) and others of that period, and illustrated in many valuable publications, by Nash, Richardson, Habershon, Clayton, Viollet de Duc, Parker, Dollman, and others; and not least of such works in timber are the barn, porches, lych gates, palings, with chests and presses, and tables and chairs formerly. Speci of car try.

Pugging floors, firring down joists, bracketing and cradling for plastering, and some other things, are operations performed indifferently by the carpenter or the joiner, as less or greater precision is required in the performance.

Joinery.

Joinery is one of the useful arts which contributes most materially to the comfort and convenience of man. As the arts of joinery and carpentry are often followed by the same individual, it appears at first view natural to conclude that the same principles are common to both these arts; but a closer examination of their objects leads to a different conclusion. The art of carpentry is directed almost wholly to the support of weight or pressure, and therefore its principles must be found in the mechanical sciences. In a building it includes all the rough timber-work necessary for support, division, or connection; and its proper object is to give firmness and stability. The art of joinery has for its object the addition in a building of all the fixed wood-work necessary for convenience or ornament. The joiner's works are many of them of a complicated nature, and require to be executed in an expensive material; therefore joinery requires much skill in that part of geometrical science which treats of the projection and description of lines, surfaces, and solids, as well as an intimate knowledge of the structure and nature of wood. A man may be a good carpenter without being a joiner at all; but he cannot be a joiner without being competent, at least, to all the operations required in carpentry. The rough labour of the carpenter renders him in some degree unfit to produce that kind of accurate and neat workmanship which is expected from a modern joiner; but it is no less true, that the habit of neatness and the great precision of the joiner make him a much slower and less profitable workman than the practised carpenter in works of carpentry. In carpentry, as before observed, framing owes its strength to the form and position of its parts; but in joinery, the strength of a frame depends upon the strength of the joinings. The importance, therefore, of fitting the joints together as accurately as possible is obvious. It is very desirable that a joiner should be a quick workman, but it is still more so that he should be a good one; that he should join his materials with firmness and accuracy; that he should make surfaces even and smooth, mouldings true and regular, and the parts intended to move so that they may be used with ease and freedom. It is also of the greatest importance that the work, when thus put together, should be constructed of such sound and dry materials, and on such principles, that the whole should bear the various changes of temperature and of moisture and dryness, so that the least possible shrinkage or swelling should take place.

Progress of joinery. In early times very little that resembles modern joinery was known; every part was rude, and joined in the most artless manner. The first dawnings of the art appear in the thrones, stalls, pulpits, and screens of our cathedrals and churches; but even in these it is of the most simple kind, and is indebted to the carver for everything that is worthy of regard. Whether in these monuments the carver and the joiner had been one and the same person we cannot now determine, though we imagine, from the mode of joining in some of them, that this was the case. With the revival of classic art great changes took place in every sort of construction. Forms began to be introduced in architecture which could not be executed at a moderate expense without the aid of new principles, and these principles were discovered and published by practical joiners. As might naturally be expected, these authors had but confused notions, with their scanty geometrical knowledge; and, accordingly, their descriptions are often obscure, and sometimes erroneous. The change from the heavy mullioned casement and its guard of iron bars to the sash windows necessitated some new method of protection, and boxing shutters were invented. The framed wainscot of small panels gave way to the large bolection moulded panelling. Heavy doors, which were fomerly hung on massive posts, or in jambs of cut stone, were now framed in light panels, and hung in moulded dressings of wood. The scarcity of oak timber, and the expense of working it, led to the importation of fir timber from the north, which gradually superseded all other material except for the choicest works. But the art is still far short of perfection, and in some respects it seems to have retrograded. It is seldom that large glued-up panels will now stand well. Mouldings of great girth give at the mitres, doors wind, and skirtings shrink from the floors in a way seldom seen in old houses. The sashes, perhaps, are made better than the heavy barred windows of a century and a half ago. In no other respect, however, has joinery made the progress which has been made in other arts. The improved state of machinery has also done but little for its excellence, though the circular saw-bench, the planing-machines, the moulding-machines, and the mortising-machines have done much to reduce the cost of labour. This last machine was suggested in the seventh edition of this work (1830), attention having been drawn to the subject from the improvements in the art of block-making, and it is now used in most of the large establishments throughout the country.

Tools. The joiner operates with saws, planes, chisels, gouges, hatchet, adze, gimblets, and other boring instruments (which are aided and directed by chalked lines), gauges, squares, hammers, mallets, and a great many other less important tools; and his operations are principally sawing and planing in all their extensive varieties, setting out, mortising, dovetailing, &c. Descriptions of the tools, with instructions for using them, may be found in Moxon's *Mechanick Exercises*, 4to, London, 1677–80, and in Nicholson's *Mechanical Exercises*, London, 1812.

There is likewise a great range of other operations, none of which can be called unimportant, such as paring, gluing up, wedging, pinning, fixing, fitting, and hanging, and many things besides which depend on nailing, &c., such as laying floors, boarding ceilings, wainscoting walls, bracketing, cradling, firring, and the like. In addition to the wood on which the joiner works, he requires also glue, nails, brads, screws, and hinges,—and accessorily he applies bolts, locks, bars, and other fastenings,—together with pulleys, lines, weights, white-lead, hold-fasts, wall-hooks, &c., &c.

The joiners' work for a house is for the most part prepared at the shop, where every convenience may be supposed to exist for doing everything in the best and readiest manner; so that little remains to be done when the carcass is ready, but to fit, fix, and hang, that is, after the floors are laid. The sashes and frames, the shutters, back flaps, backs, backs and elbows, soffits, grounds, doors, &c., are all framed and put together, that is, wedged up and cleaned off, at the shop; the flooring boards are prepared, that is, faced, shot, and gauged with a fillister rebate; and the architraves, pilasters, jamb linings, skirtings, mouldings, &c., are all got out, that is, tried up, rebated, and moulded, at the shop. The joiner very often turns the house he has to fit up into a workshop; for benches, and a fire for his glue-pot, are nearly all he requires, should he not have the now usual "general joiner" machine.

s. There is no art in which it is required that the structure and properties of wood should be so thoroughly understood as in joinery. The practical joiner, who has made the nature of timber his study, has always a most decided advantage over those who have neglected this most important part of the art.

It is well known that wood contracts less in proportion, in diameter, than it does in circumference; hence a whole
ly. tree always splits in drying. Mr Knight has shown that, in consequence of this irregular contraction, a board may be cut from a tree that can scarcely be made by any means to retain the same form and position when subjected to various degrees of heat and moisture. From the ash and the beech he cut some thin boards in different directions relatively to their tranverse septa, so that the septa crossed the middle of some of the boards at right angles, and lay nearly parallel with the surfaces of others. Both kinds were placed in a warm room, under perfectly similar circumstances. Those which had been formed by cutting across the tranverse septa, as at A in fig. 38, soon changed their form very considerably, the one side becoming hollow, and the other round; and in drying, they contracted nearly 14 per cent. in width. The other kind, in which the septa were nearly parallel to the surfaces of the boards, as at B, retained, with very little variation, their primary form, and did not contract in drying more than $3\frac{1}{2}$ per cent. in width. (*Philosophical Transactions*, part ii. for 1817; *Philosophical Magazine*, vol. l. p. 437.)

Fig. 38.

As Mr Knight had not tried resinous woods, two specimens were cut from a piece of Memel timber; and to render the result of the observations more clear, conceive fig. 38 to represent the section of a tree, the annual rings being shown by circles. BD represents the manner in which one of our pieces was cut, and AC the other. The board AC contracted 3·75 per cent. in width, and became hollow on the side marked *b*. The board BD retained its original straightness and contracted only 0·7 per cent. The difference in the quantity of contraction is still greater than in hard woods. From these experiments, the advantages to be obtained merely by a proper attention in cutting out boards for panels, &c., will be obvious; and it will also be found that panels cut so that the septa are nearly parallel to their faces, will appear of a finer and more even grain, and require less labour to make their surfaces even and smooth. But as this system would necessitate the rejection of all but the heart of the tree for superior work, a method has been adopted which it is said was first used by the billiard-table makers. Let AC, fig. 39, represent the piece above referred to by the same letters. It will become hollow on the side marked *b*, no doubt because the rings of the wood when cut across are relieved from tension, and endeavour to expand themselves. To counteract this it is customary, in all good work, to rip the plank down the centre, and then to "turn the stuff inside out" as it is popularly called. This is done by reversing the wood, end for end, so as to bring the heart against heart, and the outside against outside, as is shown in fig. 40 (without which the glue joints are sometimes liable to fly), and also so as to reverse the circular parts of the grain.

Fig. 39.

Fig. 40.

In wood that has the larger transverse septa, as the oak, for example, boards cut as BD will be figured, while those cut as AC will be plain.

There is another kind of contraction in wood whilst drying, which causes it to become curved in the direction of its length. In the long styles of framing we have often observed it; indeed, on this account, it is difficult to prevent the style of a door, hung with centres, from curving, so as to rub against the jamb. A very satisfactory reason for this kind of curving has been given by Mr Knight, which also points out the manner of cutting out wood, so as to be less subject to this defect, which it is most desirable to avoid. The interior layers of wood, being older, are more compact and solid than the exterior layers of the same tree; consequently, in drying, the latter contract more in length than the former. This irregularity of contraction causes the wood to curve in the direction of its length, and it may be avoided by cutting the wood so that the parts of each piece shall be as nearly of the same age as possible. But as this would also necessitate the rejection of a great deal of stuff, a simpler method is found, which is always to turn the heart of the wood outwards. Thus, in framing a door, the heart should always go against the jambs, and the sap side to the panels.

Besides the contraction which takes place in drying, wood undergoes a considerable change in bulk with the variations of the atmosphere. In straight-grained woods the change in length is nearly insensible, and hence they are sometimes employed for pendulum rods; but the lateral dimensions vary so much that a wide piece of wood will serve as a rude hygrometer. The extent of variation decreases in a few seasons, but it is of some importance to the joiner to be aware that even in very old wood, when the surface is removed, the extent of variation is nearly the same as in new wood.

It appears from Rondelet's experiments (*L'Art de bâtir*, article "Menuiserie," tom. iv. p. 425, 1814), that in wood of a mean degree of dryness, the extent of contraction and expansion, produced by the usual changes in the state of the atmosphere, was, in fir wood, from $\frac{1}{380}$ to $\frac{1}{75}$ of its width, and in oak, from $\frac{1}{412}$ to $\frac{1}{84}$. Consequently, the mean extent of variation in fir is $\frac{1}{124}$, and in oak, $\frac{1}{140}$; and, at this mean rate, in a fir board about $12\frac{1}{2}$ inches wide, the difference in width would be $\frac{1}{10}$th of an inch. This will show the importance of attending to the maxims of construction we have already laid before the reader; for, if a board of that width should be fixed at both edges, it must unavoidably split from one end to the other.

The kinds of wood commonly employed in joinery are —the oak, the different species of pine, mahogany, and sometimes lime-tree and poplar. Of the oak there are two species common in Britain; that which Linnæus has named *Quercus Robur* is the most valuable for joiners' work; it is of a finer grain, less tough, and not so subject to twist as the other kind. Oak is also imported from the Baltic ports, from Germany (that known as wainscot), and from America. These foreign kinds being free from knots, of a straighter grain, and less difficult to work, they are used in preference to British species. The greater part of joiners' work is executed in fir imported from the north of Europe. Yellow fir is used for outside work, as doors and sashes, and for floors where there is likely to be much wear. Very good red pine deals have been imported from Canada. Inside work is almost always framed of white fir. Some very good panels when not too wide, and excellent mouldings, are made of American pine. White fir is often used for internal work, and yellow pine is much used for mouldings. The forest of Braemar, in Aberdeenshire, furnishes yellow fir of an excellent quality, little inferior to the best foreign kinds. For the general purposes of joinery, the wood of the larch seems to be the best; this useful tree thrives well on the Scottish hills. Some fine specimens of it have been obtained from Blair- Kinds of wood.

Athol. It makes excellent steps for stairs, floors, framing, and most other articles. Mahogany, in joinery, is only used where painted work is improper, as for the hand-rails of stairs, or for the doors and windows of principal rooms. For doors it is not now so often used as it was formerly, its colour being found to be too gloomy to be employed in large masses. Lime-tree, and the different species of poplar, make very good floors for inferior rooms; and may often be used for other purposes, in places where the carriage of foreign timber would render it more expensive. Lime-tree is valuable for carved work, and does not become worm-eaten; but carving is at present seldom used in joinery.

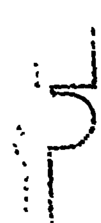
From these timbers, the oak and fir especially, the joiner obtains the battens, fillets, boards, and planks, with which he performs all his works, cutting them into scantlings and thin deals as he requires them.

Battens. Battens are narrow boards running from half an inch to an inch and a half or 2 inches thick, and from 3 to 6 or 7 inches wide. A piece of stuff of too small a scantling to

Boards. be a batten is called a fillet. The term board is applied to sawed stuff when its width exceeds that of a batten, and its thickness does not exceed 2 inches or 2½ inches.

Planks. The term plank is applied to large pieces of stuff whose width is great in proportion to their thickness, and whose thickness nevertheless does not exceed 3 or 4 inches. In London these terms are used in much more restricted senses than they are here described to mean, because of the fixed and regular sizes and forms in which stuff for the joiner's use is for the most part brought to market there. A batten, to a London joiner, is a fine flooring board from an inch to an inch and a half in thickness, and just 7 inches wide. A board is a piece cut from the thickness of a deal whose width is exactly 9 inches; and nearly everything above that width, and not large enough to be called a scantling of timber, is a plank.

Mouldings. Mouldings, in the Roman and Italian styles, as used in joinery, are generally composed of parts of circles, and differ somewhat from those used in stone. (See Plates XIII., &c., illustrating the article ARCHITECTURE, in vol. ii.) Mouldings are almost the only part of modern joiners' work which can, in strictness, be called ornamental, and consequently that in which the taste of the workman is most apparent. The form of them should be distinct and varied, forming a bold outline of a succession of curved and flat surfaces, disposed so as to form distinct masses of light and shade. If the mouldings be of considerable length, a greater distinction of parts is necessary than in short ones. Those for the internal part of a building should not, however, have much projection; the proper degree of shade may always be given, with better effect, by deep sinkings judiciously disposed. The light in a room is not sufficiently strong to relieve mouldings, without resorting to this method; and hence it is that quirked and under-cut mouldings are so much esteemed. The following present



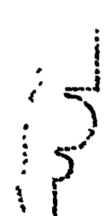


FIG. 41. Rounded Edge. FIG. 42. Bead. FIG. 43. Torus. FIG. 44. Torus and Bead.

the convex side to the eye:—fig. 41 is merely a rounded edge; fig. 42, of small size, is a bead; fig. 43, of larger size, a torus; and fig. 44 shows the torus and bead together. If there be a deep sinking under a bead (as fig. 45), it is called a quirked or cock bead; if there be two

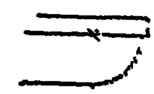

FIG. 45. Quirked Bead. FIG. 46. Double-quirked Bead. FIG. 47. Reeds. FIG. 48. Ovolo.

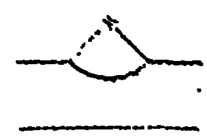
such sinkings, so as to show three-quarters of a circle in the bead, it is called (fig. 46) a double-quirked bead: two or more beads, side by side (as fig. 47) are called reeds:



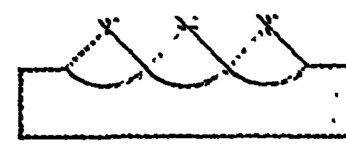


FIG. 49.—Hollow. FIG. 50.—Flutes.

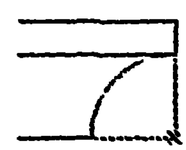
the fourth part of a circle, or half a bead (as fig. 48), is called an ovolo, or quarter round. A moulding composed of two convex parts is also called an ovolo, the upper part



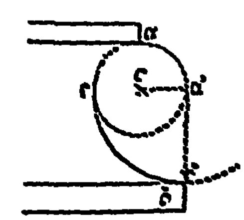


FIG. 51.—Cavetto. FIG. 52.—Scotia.

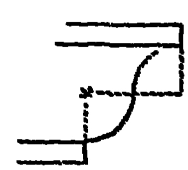
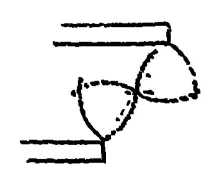
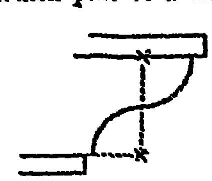
of the curve being continued round into the bed similar to a quirk, as fig. 44. In concave mouldings a simple curved grooving, as fig. 49, is called a hollow, and two or more

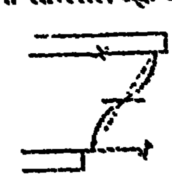




FIGS. 53, 54.—Forms of Cyma recta.

such grooves are flutes, as fig. 50. A hollow forming the fourth part of a circle is called a cavetto, fig. 51; a





FIGS. 55, 56.—Forms of Cyma reversa.

deep hollow between two fillets, as used in base mouldings, is a scotia, fig. 52. Mouldings which are partly convex

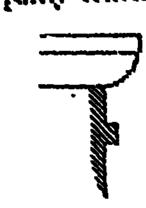


FIG. 57. Rebate. FIG. 58. Groove. FIG. 59. Necking. FIG. 60. Fillet.

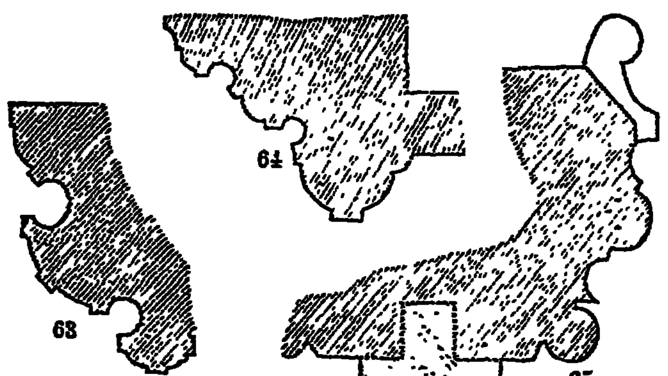
and partly concave, are of two sorts, the cyma recta, as figs. 53 and 54, and the cyma reversa or ogee, as figs. 55 and

56, which may be made of greater or less projection. Grecian mouldings are all similar in principle, but the parts are of conic sections instead of circles, as explained above, p. 473.

A plain square sinking on the edge of a board, as fig. 57, for the purposes of framing, is called a rebate; if away from the edge, as fig. 58, a groove; placed under a cap (as fig. 59), or as a necking (as fig. 60), it is called a fillet; three such fillets under an ovolo, when composing part of the capital of a column, are called annulets. In all kinds of framing the mouldings which rise above the styles are called bolection mouldings (see fig. 82).

The mouldings during the mediæval period used by the carpenter and joiner, who were perhaps the same person, seldom varied from those cut by the mason, except that they were somewhat more refined and less in size, as appropriate to the material out of which they were to be cut. "They are such as would not be executed in any other material; they are sharp, delicate, minute, and quaintly under-cut. Every curve is subtle; every alternation of round and flat and hollow thoughtfully contrived, graceful, and yet vigorous; they are very often unlike any stone mouldings," says Mr G. E. Street, in a lecture in 1865 on "English Woodwork in the 13th and 14th Centuries," printed in the *Transactions of the Royal Institute of British Architects*. "In the stalls at Selby there is an elaborate cap only $1\frac{3}{4}$ inches in height; and at Winchester a band $\frac{5}{8}$ths of an inch in height, and yet consisting of four distinct members, and showing in elevation as many as eight distinct lines." The woodcuts appended will suffice to explain the author's meaning. Fig. 61 is a mullion from stalls at Winchester Cathedral, and fig. 62 from St Mary's Hospital at Chichester. Figs. 63 and 64 are arch mouldings from the same stalls; and fig. 65, the cornice of a screen in Old Shoreham church. Fig. 66 is a cap and base from the stalls at Winchester.

FIGS. 61, 62.—Mediæval Mullions.



FIGS. 63, 64, 65.—Mediæval Mouldings and Cornice.

When an inclined or raking moulding is intended to join with a level moulding, at either an exterior or an interior angle, the form of the level moulding being given, it is necessary that the form of the inclined moulding should be determined, so that the corresponding parts of the surfaces of the two mouldings should meet in the same plane, this plane being the plane of the mitre. This may be otherwise expressed by saying that the mouldings should mitre truly together.

ding
les.

When the length of a joint at an angle is not considerable, it is sufficient to cut the joint in such a manner that when the parts are joined, the plane of the joint shall bisect the angle. This kind of joint is shown for two different angles, by fig. 67, and is called a mitre. When an angle of considerable length is to be joined, and the kind of work does not require that the joining should be concealed, fig. 68 is often employed; the small bead renders the appearance of the joint less objectionable. because any irregularities from shrinkage are not seen in the shade of the quirk of the bead. A bead upon an angle, where the nature of the work does not determine it to be an arris, is attended with many advantages; it is less liable to be injured, and admits of a secure joint without the appearance of one. Fig. 69 shows a joint of this description, which should always be used in passages. Fig. 70 represents a very good joint for an exterior angle, whether it be a long or a short one. Such a joint may be nailed both ways. But the joint represented by fig. 71 is superior to it; the parts, being drawn together by the form of the joint itself, can be fitted with more accuracy, and joined with certainty. The angles of pilasters are often joined by this last method. Interior angles are commonly joined as shown in fig. 72. If the upper or lower edge be visible, the joint is mitred, as in fig. 67, at the edge only, the other part of the joint being rebated, as in fig. 70. In this manner are put together the skirting and dado

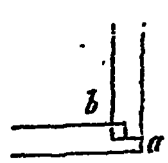

FIG. 75.—Lap-dovetail.

parts of joiners' work. Fig. 73 is an excellent method of joining angles for drawers, frames for lead cisterns, boxes,

&c., and is commonly called a dovetail. If a portion of the junction is cut off at an angle of 45°, as fig. 74, while the portion at *b* is dovetailed, it is called a *mitre dovetail;* while if the portion at *a* (in fig. 75) passes the other portion at right angles, it is called a *lap-dovetail.* A very good joint is shown in fig. 76, the angles being brought together at an angle of 45°, two or more saw curfs are cut with a dovetail saw, and thin pieces of wood glued in as shown; this is called a *keyed mitre.*

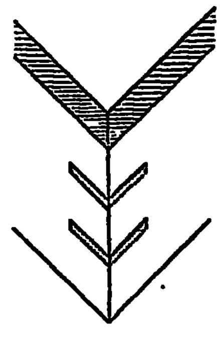

FIG. 76.—Keyed Mitre.

Fig. 77 shows four methods for securing planks together as practised in France during the mediæval period, from Viollet le Duc's *Dictionnaire.* He does not appear to show the junction formed by running a tongue of one piece through another piece and pinning it on the outside, as practised now in England in furniture, as tables, &c.

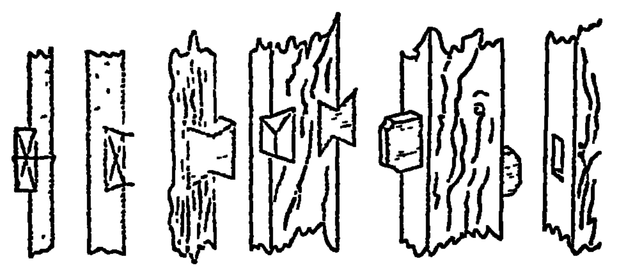

FIG. 77.—Mediæval Joints.

lue. Glue is a viscid tenacious matter used as a cement to connect objects together. The common or animal glue is made from certain portions of animals reduced after certain processes by boiling to the required consistency, and dried in cakes. The best marine glue is composed of caoutchouc dissolved in naphtha, to which shellac is added, and heated until amalgamated. It is insoluble in water, sufficiently solid to give strength, and adhesive to an intense degree. Glue is used principally in putting framed work together, but not at all in fixing; and even for the former purpose it is much less used by good workmen than by bungling hands. When the stuff is well seasoned, and the trying up, setting out, mortising, and tenoning are well and accurately executed, there is no necessity for glue on the tenons and shoulders; the wedges alone need be glued, to attach them to the sides of the tenons, that their effect may not depend on mere compression. Joiners are generally furnished with a cramp, with which to force the joints of framing into close contact; it is either of wood acting by means of wedges, or of iron with a screw. This, too, is unnecessary with good work, every joint of which may be brought perfectly close without great violence of any kind. The cramp will sometimes give bad work the semblance of good, but it cannot make it really so. If any cracking and starting be heard in the joiner's work of a new building, it generally indicates one of two things: either the cramp has been required in putting the framing together, or, having been put together, it has been forced out of winding in fixing, and the constrained fibres are seeking to regain their natural position. A good workman does not require cramp, nor will his work, if he has been supplied with seasoned stuff, ever require to be strained; and consequently the cracking and starting of joiners' work indicate unfit stuff or bad work, or perhaps both, It is true that glued joints will sometimes fly; but when they do, there need be no hesitation in determining the presence of both bad work and stuff in an improper state.

ramping.

Joining with glue.

It is seldom possible to procure boards sufficiently wide for panels without a joint, on account of heart shakes, which open in drying. In cutting out panels, for good work, shaken wood should be carefully avoided. That part near the pith is generally the most defective. If the panels be thick enough to admit of a cross or feather tongue in the joint, one should always be inserted, for then, if the joint should fail, the surfaces will be kept even, and it will prevent light passing through. A very good way also is to glue a piece of strong canvas on the back of the panel when the work is not intended to be seen on both sides. Sometimes plane surfaces of considerable width and length are introduced in joiners' work, as in dado, window backs, &c.; such surfaces are commonly formed of inch or inch and quarter boards joined with glue, and a cross or feather tongue ploughed into each joint. When the boards are glued together, and have become dry, tapering pieces of wood, called keys, are grooved in across the back with a dovetailed groove. These keys preserve the surface straight, and also allow it to shrink and expand with the changes of the weather. It would be an endless task to describe all the methods that have been employed to glue up bodies of such varied forms as occur in joinery; for every joiner forms methods of his own, and merely from his being most familiar with his own process, he will perform his work, according to it, in a better manner than by another, which to an unprejudiced mind has manifestly the advantage over it. The end and aim of the joiner, in all these operations, is to avoid the peculiar imperfections and disadvantages of his materials, and to do this with least expense of labour or material. The straightness of the fibres of wood renders it unfit for curved surfaces, at least when the curvature is considerable. Hence, short pieces are glued together as nearly in the form desired as can be, and the apparent surface is covered with a thin veneer; or the work is glued up in pieces that are thin enough to bend to the required form. Sometimes a thin piece of wood is bent to the required form upon a cylinder or saddle, and blocks are jointed and glued upon the back; when the whole is completely dry it will preserve the form that had been given to it by the cylinder. The curve should be made a little "quicker" than the curve intended, as the stuff will always spring back a trifle on being released. A piece of work glued up in thicknesses should be very well done; but it too often happens that the joints are visible, irregular, and in some places open; therefore other methods have been tried.

Large pieces of timber should never be used in joinery, because they cannot be procured sufficiently dry to prevent them splitting with the heat of a warm room. Therefore, the external part of columns, pilasters, and works of a like kind, should be formed of thin pieces of dry wood; and, if support be required, a post, or an iron pillar, may be placed within the exterior column. Thus, to form columns of wood, so that they shall not be liable to split, narrow pieces of wood are used, not exceeding 5 inches in width. These are jointed like the staves of a cask, and glued together, with short blocks glued along at each joint. Fig. 78 is a plan of the lower end of a column glued up in staves; the bevel at A is used for forming the staves, that at B is used for adjusting them when they are glued together. A similar plan must be made for the upper end of the column, which will give the width of the upper end of the staves. The bevels taken from the plan, as at A and B,

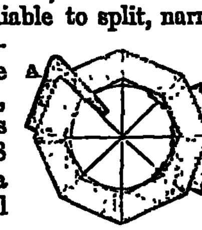

FIG. 78.—Jointing of Column.

are not the true bevels; but they are those generally used, and are very nearly true when the columns are not much diminished. The same method may be adopted for forming large pillars for tables, &c. If a column have flutes, with fillets the joints should be in the fillets, in order to make the column as strong as possible; also, if a column be intended to have a swell in the middle, proper thickness of wood should be allowed for it. When columns are small they may be made of dry wood, and turned in a lathe, when they can be moulded at the same time. Balusters for stairs are made thus. To secure small columns against splitting, a hole should be bored down the axis of each column

ıg If a piece of wood be boiled in water for a certain time, and then taken out and immediately bent into any particular form, and it be retained in that form till it be dry, a permanent change takes place in the mechanical relations of its parts; so that though, when relieved, it will spring back a little, yet it will not return to its natural form. The same effect may be produced by steaming wood; but though both these methods have been long practised to a considerable extent in the art of ship-building, we are not aware that any general principles have been discovered either by experiment or otherwise, that will enable us to apply them in joinery, where so much precision is required. They do not seem to have been tried; and before they can be rendered extensively useful, the relation between the curvature to which the wood is bent, and that which it assumes when relieved, should be determined, and also the degree of curvature which may be given to a piece of a given thickness. The time that a piece of wood should be boiled or steamed, in order that it may be in the best state for bending, should be made the subject of experiments; and this being determined, the relation between the time and the bulk of the piece should be ascertained. A novel and very simple and effective way of boiling sash-bars or thin articles has been adopted,

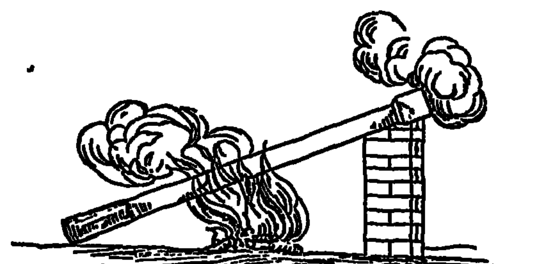

FIG. 79.—Boiling Sash-bars.

as shown in fig. 79. Take a piece of common cast-iron pipe of sufficient diameter, stop up one end with a plug of wood driven tight, fill the pipe with water, raise one end in a sloping position, leaning it on a pile of bricks, and kindle a fire under the pipe. For the joiner's purposes the process might perhaps be greatly improved by saturating the convex side of each piece with a strong solution of glue immediately after bending it. By filling, in this manner, the extended pores, and allowing the glue to harden thoroughly before relieving the pieces, they would retain their shape better.

ning. The object in framing is, to reduce the wood into narrow pieces so that the work may not be sensibly affected by its shrinkage; and, at the same time, it enables us to vary the surface without much labour. Besides this, as the strains from the grain of the wood are in different directions, the work is prevented from winding on its face. From this view of the subject, the joiner will readily perceive that neither the parts of the frame nor the panels should be wide. And as the frame should be composed of narrow pieces, it follows that the panels should not be very long, otherwise the frame will want strength. The panels of framing should not be more than 15 inches wide and 4 feet long, and panels so large as this should be avoided as much as possible. The width of the framing is commonly about one-third of the width of the panel. Frames in joinery are usually connected by mortise and tenon joints, with grooves to receive the panels. Wainscoting, doors, window-shutters, &c., are framed in this manner.

In framing or framed work, the outer vertical bars which are mortised are called styles; and the transverse, those on whose ends the tenons are formed are called rails (Plate XXVI. fig. 2). In doors the open spaces or squares formed internally by the rails and styles are divided in the width by bars parallel to the styles. These are tenoned into the rails, and are called munnions or mountings, or, vulgarly, *muntins*. The frame being formed by trying up, setting up, mortising, and tenoning, the inner or face edges of the styles, and of the highest and lowest rails, and both edges of the muntins and of the inner rails, are grooved with the plough to receive the edges and ends of the filling-in parts or panels of the framework. Panels are either flat, raised, or flush (Plate XXVI. fig. 3). Flat panels are no thicker than the grooves into which they are fitted, and consequently their faces are as much below the surface of the framing as the groove is in from each side of the styles and rails. Raised panels are thicker than the groove in the framing, but are not so thick as to reach the surface; nor is the panel thickened through its whole extent. It fits exactly into the groove, and thickens gradually for an inch or two, and then sets off at a right angle with the surface, increasing suddenly three or four sixteenths of an inch. A panel may be raised on one side only, or on both sides. Flush panels are rebated down from one face to the distance the plough groove is in from the surface of the framing; and the back of a panel thus rebated on one side is worked down to be even with the other edge of the groove, leaving a tongue to fit it exactly; for if it be required to make panels flush on both sides, this is generally effected by filling in on the back or flattened side with an extraneous piece. Panels of external doors and shutters may be rendered more secure by boring them, and inserting iron wires, as noticed in the *Transactions of the Society of Arts*, vol. xxv. p. 106. Framing is not, however, often finished in the manner above described, especially with raised and flush panels; mouldings are generally introduced, and are either struck or worked in the solid substance of the framing, or are in separate pieces or slips, and laid in with brads. If a moulding be struck or laid in on one side only, and the other is left plain, the framing is described as moulded and square, a flat panel being in that case understood; if the panel be raised the framing will be described as moulded with a raised panel on one side, and square or flush on the other. It may be moulded with a flat panel, or moulded with a raised panel, on both sides; and the moulding may, as before intimated, be either struck in the solid or laid in any of the preceding cases. Mouldings which are laid in round the panels of framing are neatly mitred at the angles, and bradded, to appear as much as possible as if they were struck in the solid. In nailing or bradding the mouldings, the brads should be driven into the framework, and not into the panels. Framing with sunk panels, in some kinds of work, has the edges of the rails and styles either stop-chamfered or slightly curved. With a flush panel the moulding is always either a bead, or a series of beads called *reeds*; and is, in the case of a single bead, which is most common, always struck on the solid frame, and the work is called bead-flush; but reeds are generally struck on the panel in the direction of the grain, and laid in on the panel across it, or along the ends; this is termed reed-flush.

Boarding on joists for a flat

Flush panels in inferior works have a single bead struck on their sides in the direction of the grain alone, the ends abutting plainly, and this is termed bead-butt, the fact that the panels are flush being inferred.

The plainest quality of framing, in which it is square on both sides, is used in the fittings of inferior bed-rooms, inner closets, and the plainer domestic offices, but always internally; framing moulded on one or both sides, in rooms and places of a greater degree of importance, and in places where the work may be more generally seen; in some cases a flat panel may be enriched by a small moulding laid on its surface, leaving a margin between it and the larger moulding at its extremities. This may be done in drawing-rooms and apartments of that class, especially if they be in an upper story; and raised panels should be confined to the framed fittings of dining-rooms and other apartments on a ground or principal story. Framing with flush panels is almost restricted to external doors, &c., one side of a door being bead-flush, and the other flat and moulded, perhaps, or the face may be moulded with a raised panel, and the back bead-flush; and this for principal entrances. Bead-butt framing is found in external doors to offices, &c. Partitions between rooms are often made of framing as above described. Lately some sliding partitions have been put forward, one of which consists of two or three large sliding framings, and felt is relied upon to render them sound proof. This is by Stone; while that by Williams consists of a series of framings pivoted at top and bottom, and with the pivots running on grooves at top and bottom, so that the shutters may be formed into a pilaster-like mass at the side of the room.

:ises tenons frames. It is of the utmost importance in framing that the tenons and mortises should be truly made. After a mortise has been made with the mortise chisel, it should be rendered perfectly even with a float,—an instrument which differs from a single cut or float file only by having larger teeth. An inexperienced workman often makes his work fit too tight in one place, and too easy in another, hence the mortise is split by driving the parts together, and the work is never firm; whereas if the tenon fill the mortise equally, without using any considerable force in driving the work together, it is found to be firm and sound. The thickness of tenons should be about one-fourth of that of the framing, and the width of a tenon should never exceed about five times its thickness, otherwise, in wedging, the tenon will become bent, and bulge out the sides of the mortise. If the rail be wide, two mortises should be made, with a space of solid wood between; fig. 80 shows the tenons for a wide rail. If the tenon occurs at the end of a piece of framing, it must be set back a little, so as to allow sufficient solid wood to form a sound mortise; this is called a haunching (see *e*, fig. 81). In thick framing, the strength and firmness of the joint is much increased by putting a cross or feather tongue in on each side of the tenon;

FIG. 80.—Tenons for w de Railing.

these tongues are about an inch in depth, and are easily put in with a plough proper for such purposes. The projected figure of the end of a rail, as in fig. 80, shows these tongues put in; in the style there are grooves ploughed to receive them. Sometimes these projections are left in the solid wood itself, in which case they are called *stump tenons*. Sometimes, in thick framing, a double tenon in the thickness is made; but we give the preference to a single one, when tongues are put in the shoulders, as we have described; because a strong tenon is better than two weak ones, and there is less difficulty in fitting one than two. The panels of framing should be made to fill the grooves, so as not to rattle, and yet to allow the panels to shrink without splitting. When the mouldings are stuck on the framing, as is often the case in large stuff, it becomes necessary to find the lines to bring the angles together. In square framing, this is done simply by cutting *a b*, *c d*, as in fig. 81, at a mitre; but if the framing be oblique angle, it is done by scribing; the angle at *a b* being determined by the eye, *c d* is cut parallel to it. Where large projecting or bolection mouldings are used, the French have a very excellent way of framing (fig. 82), which it would be well to imitate in this country. Here C is the panel round which the moulding B is framed and mitred, the whole is then framed into A, which is a section both of the styles and rails.

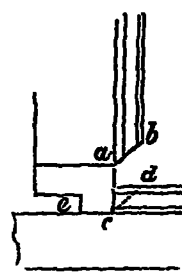

FIG. 81.—Fitting Mouldings to Framing.

When a frame consists of curved pieces they are often joined by means of pieces of hard wood called keys. Fig 83 is the head of a Gothic window frame joined with a key, with a plan of the joint below it. A cross tongue is put in on each side of the key, and the joint is tightened by means of the wedges, *a*, *a*. It is, however, a better method to join such pieces by means of a screw bolt instead of a key, the cross tongues being used whichever method is adopted. Where the ends of the bolts cannot be allowed to project, they should be fixed as *bed bolts*.

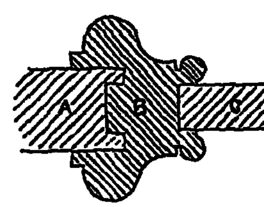

FIG. 82.—Bolection Mouldings.

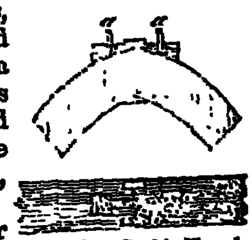

FIG. 83.—Gothic Keyed Frame.

Doors. *Doors* are made two and four panelled for the most part when the panels are flat and the framing square, six-panelled when the latter is moulded, and six, eight (as figs. 2 and 3, Plate XXVI., to which the details in the following description will apply), or even ten-panelled when the framing is of the superior descriptions. Doors which are hung in two equal widths to occupy the doorway, and are hung to the opposite side posts or jambs of the frame, are said to be folding-doors or double-margined,—that is, the styles or margins are repeated necessarily in the middle where they meet. The style, muntin, and rails to doors are the same as in framing or wainscoting; and the panels may be moulded in the same manner. Doorways are fitted with jamb linings, and architraves or pilasters. Jamb linings, as A in fig. 86, when they exceed 9 or 10 inches in width, should always be so framed to correspond with the door on the outer faces; or they may be made solid. Narrow and plain jamb linings to inferior rooms are rebated on one side of the lining only, and the rebate forms the frame into which the door is fitted. To superior work they are rebated on both sides, as if it were intended to put a door on each side. The jambs are fixed to the inner edges of the grounds, which are fixed to the wall to receive the architrave or other decorations to the opening, and to stop the plastering; if they are wide, and not framed, backings are put across to stiffen them; and these backings are dovetailed into the edges of the grounds.

It requires a considerable degree of care to hang a door, a shutter, or any other piece of work in the best manner. In the hinge, the pin should be perfectly straight, and truly cylindrical, and the parts accurately fitted together. The hinges should be placed so that their axes may be in Hanging doors.

the same straight line, as any defect in this respect will produce a considerable strain upon the hinges every time the hanging part is moved, will prevent it from moving freely, and is injurious to the hinges. In hanging doors, centres are often used instead of hinges; but, on account of the small quantity of friction in centres, a door moves too easily, so that a slight draught of air accelerates it so much in falling to, that it shakes the building, and is disagreeable. This may be in some degree remedied by placing a small spring to receive the shock of the door.

The greatest difficulty, in hanging doors, is to make them to clear a carpet, and be close at the bottom when shut. To do this, that part of the floor which is under the door when shut, or the width of the jambs, may have a piece of wood about a quarter of an inch thick above the general level of the floor, which, with placing the hinges so as to cause the door to rise as it opens, will be sufficient unless the carpet should be a very thick one. Several mechanical contrivances have been used for either raising the door, or adding a part to spring close to a floor as the door shuts. The best method now in use, and the simplest, is the invention of the rising or skew-butt hinge. The parts of this which bear on each other are made with a double bevel, so that, if more than half opened, the door falls against the wall by its own weight; if less than half open, it closes itself.

Various kinds of hinges are in use. Sometimes they are concealed, as in the kinds of joints called rule joints; others project, and are intended to let a door fold back over projecting mouldings, as on pulpit doors and outside folding shutters. When hinges project, the weight of the door acts with an increased leverage upon them, and they soon get out of order, unless they be strong and well fixed. The door of a room should be hung so that, in opening the door, the interior of the room cannot be seen through the joint. This may be done by making the joint according to fig. 84. The bead should be continued round the door, and a common butt-hinge answers for it

FIG. 84.—Door-Joint.

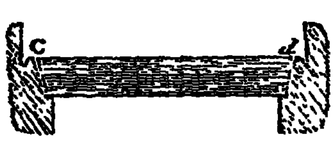

FIG. 85.—Bevel for Edge of Door.

The proper bevel for the edge of a door or sash may be found by drawing a line from the centre of motion C (fig. 85) to *e*, the interior angle of the rebate; *e d* drawn perpendicular to C *e* gives the bevel required. In practice the bevel is usually made less, leaving an open space in the joint when the door is shut; this is done on account of the interior angle of the rebate often being filled with paint.

The extension of the principle of ploughing and tonguing work together is one of the most important of the improvements that have been introduced by modern joiners. It is an easy, simple, and effectual method of combination, and one that provides against the greatest defect of timber-work, its shrinkage. By means of this method, the bold mouldings of mediæval architecture can be executed with a comparatively small quantity of material; and even in the mouldings of modern architecture it saves much labour. For example, the moulded part of an architrave may be joined with the plain part, as shown by fig. 86. If this method be compared with the old method of glueing one piece upon another, its advantage will be more evident.

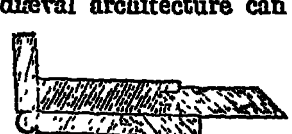

FIG. 86.—Joining of Architrave.

Architraves. Architraves and pilasters are variously sunk and moulded according to the fancy of the designer. They are fixed to the grounds with their internal edges exactly fitting to the rebates in the jambs, and they form the enriched margin or moulding of the frame in which the door is set. Architraves are mitred at the upper angle, but pilasters have generally a console or an enriched block or cap resting on them, to which they fit with a square joint; both the one and the other either run down and are scribed to the floor, or rest on squared blocks or bases, which may be the height of the skirting board, or of the whole base.

Fixing grounds. The architraves, skirtings, and surbase mouldings, are fixed to pieces of wood called *grounds*, as A, fig. 86; and as the straightness and accuracy of these mouldings depend upon the care that has been taken to fix the grounds truly, it will appear that fixing grounds, which is a part often left to inferior workmen, in reality requires skill and attention; besides, they are almost always the guide for the plasterer. Where the plasterer's work joins the grounds, they should have a small groove ploughed in the edge to form a key for the plaster. In old work the ground was generally hidden, but in modern work it is frequently shown, which is a saving of stuff; thus, instead of architraves being prepared

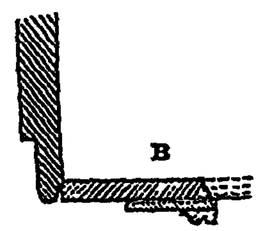

FIG. 87.—Door-Jamb and Ground.

FIG. 88.—Ground and Mouldings.

as in fig. 86, they are made as shown in fig. 87, where A is the rebated and beaded door-jamb, and B the ground, which is generally splayed at the back as a key to the plastering instead of being grooved. On this a thin piece of stuff is bradded to form the double-faced architrave, instead of sinking out of the solid, and on this the ogee or ovolo moulding is nailed. Again with base mouldings, A (fig. 88) is the ground fixed against the wall, on the top of which is nailed the upper moulding B, and C shows the skirting and lower moulding, fixed against a fillet on the floor.

Fixing joiner's work. We have thus far spoken chiefly of joinery as performed at the bench; but by far the most important part remains to be considered; for, however well a piece of work may have been prepared, if it be not properly fixed, it cannot fulfil its intended purpose. As in the preceding part, the general principles will be stated that ought to be made the basis of practice; and these illustrated by particular examples. When the carcass of a building is ready for the joiner, the first thing to be done is to cut the bond timber out of the openings, set the sash frames, and fill them with old sashes or with oiled paper on frames, to exclude the weather, but admit light. The flooring joists are then proved with straight-edges, and any inequalities in them are removed with the adze; the flooring boards are next cut down to their places, and are turned with their faces downwards until the ceilings are done. First, however, the pugging is done, if any be intended. This is to prevent sound passing through the floor when finished, and is sometimes called deafening sound-boarding. It is effected by nailing fillets to each side of the joists, near the bottom, and laying on these pieces of rough boards across

and close together; then there is put a layer of mortar mixed with chopped straw, or sometimes clay, sawdust, or small shells.

oring. The preparation given to flooring boards in superior work is planing the face, shooting the edges, and gauging to a thickness,—the common fillister or stop rebate plane being used to work down to the gauge mark, from the back of every board, and about half an inch in on each edge. When a board is to be laid, it is turned on its face in the place it is to occupy, and the workman with his adze cuts away from the back over every joist down to the gauge rebate, so that on being turned over it falls exactly into its place, and takes the same level with all its fellows, which have been brought to the same gauge; then follows the process of laying, and the result must, if the work be done well, be a perfectly even and level surface. The slight inequalities of surface which may occur are reduced with a smoothing-plane, the brads being previously punched below the surface if the floor be face-nailed. Floors are in ordinary cases either laid straight joint or folding, and are edge-nailed, as fig. 89, or face-nailed. According to the folding method, two boards are laid, their heading joints all on the same joist, and of course in the same straight line, and nailed at such a distance apart that the space is a little less than the aggregate width of the three, four, or five boards intended for it; these boards are then put to their places, and, on account of the narrowness of the space left for them, they rise like an arch between its abutments. The workmen force them down by jumping upon them. Accordingly, the boards are never soundly fixed to the joists, nor can the floor be laid with any kind of evenness or accuracy. This method should be avoided in all good work. Straight joint flooring is when every board is laid separately, or one at a time, the heading joint or joints being broken or covered regularly in every case. Dowelling is the driving-pins of wood or iron half their length, into the edge of the last laid board, the outer edge of which has been skew-nailed, their other ends running into holes prepared for them in the inner edge of the next board, in the way the head of a cask is held together, and then its outer edge is skew-nailed in the same manner, and so on. Tonguing is effected by grooving both edges of every board, and fitting thin slips and tongues into them. The boards are usually forced together by pressure as with a clamp applied to the outer edge. The nail used in face-nailing floors is called a flooring brad; it has no head, but a mere tongue projecting on one side of the top of the nail, which is put in the direction of the grain, that it may admit of being punched in below the surface level, otherwise the superficial inequalities could not be reduced when the floor was completed, because of the projecting heads of the nails. For side or edge nailing, however, clasp-nails, nails whose heads extend across on two of the opposite sides, are used.

As boards can seldom be got long enough to do without joints, it is usual, except in very inferior work, to join the ends with a tongued joint, as shown in fig. 89, where B

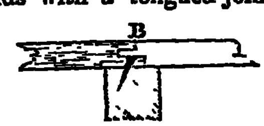

FIG. 89.—Tongued Joint.

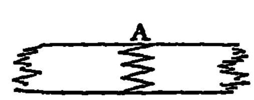

FIG. 90.—Forked Boards.

is the joint. The etched board is first laid, and edge-nailed to the joist. In oak floors the ends are forked together sometimes, as shown at A (fig. 90), in order to render the joints less conspicuous. The joints should be kept as distant from one another as possible.

In laying floors the advice of Evelyn only to tack the boards down the first year, and nail them down for good the next, is certainly the best method when it is convenient to adopt it; but, as this is very seldom the case, we must expect the joints to open more or less as the wood has been more or less seasoned. Now, these joints always admit a considerable current of cold air; and also, in an upper room, unless there be a counter floor, or pugging, the ceiling below may be spoiled by spilling water, or even by washing the floor. To avoid these disagreeable results, the boards should be ploughed and a tongue inserted into each joint, according to the old practice. When the boards are narrow, they might be laid without any appearance of nails, in the same way as a dowelled floor is laid, the tongue serving the same purpose as the dowels. In this case the cross or feather tongues for the joints should be used. A new system of flooring has for some years been used in London, to which the name of "Victoria floors" has been given. A rough floor of boards, three-quarters of an inch thick, is first laid, and the rest of the joiners' work fixed, and the plastering finished. When all is done, a floor formed of inch or inch and quarter plank, ripped down the middle, and consequently very little more than 5 inches wide, is laid; the rough boarding being first covered with a layer of shavings, or old newspapers, or other waste paper. These boards are dowelled on one edge and nailed on the other, and a very sound floor is thus formed, which neither springs nor creaks. A wainscot floor can be laid well on this principle.

Another early operation in joinery is the fixing of the framed grounds for the doors and windows, and for the skirting (Plate XXVI. fig. 5, and woodcuts, figs. 86, 87, and 88) to which the plasterers may float their work. The skirting grounds are generally dovetailed at the angles, and are well blocked out, so that they may not vibrate on being struck, or yield to pressure when the plasterer's straight-edge passes roughly over the surface; they must also be set with the utmost truth and precision. When the floors are cut down and the grounds fixed, the joiner's operations in a building should be suspended until the plasterers have finished, or nearly so, and then the floors may be laid. By deferring this operation until that period, the workmen of the two different trades are prevented from interrupting each other, and indeed injuring each other's work; and joiners always find employment in the shop preparing, as before intimated. Fixing frames

If the part to be fixed consists of boards jointed together, but not framed, it should be fixed so that it may shrink or swell without splitting or winding. The nature of the work will generally determine how this may be effected. Let us suppose that a plain back of a window is to be fixed. Fig. 91 is a section showing B the back of the window, A the window-sill, D the floor, C the skirting, and E the wall of the house. The back is supposed to be prepared as previously stated, and is kept straight by a dovetailed key *a*. Now, let the back be firmly nailed to the window-sill A, and let a narrow piece *d*, with a groove and cross tongue in its upper edge, be fixed to bond timbers or plugs in the wall, the tongue being inserted also into a corresponding groove in the lower edge of the back B. It is obvious, that the tongue being loose, the back B may contract or expand, as a panel in a frame.

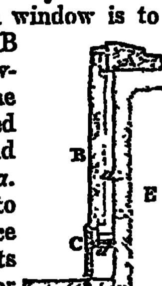

FIG. 91.—Back of a Window.

In getting out skirtings, if the work be of a superior description, the boards should be tried up as for framing in every way except bringing to a width, which need not be done. The face edges, however, must be worked with great precision, and moulded or rebated as the case may require. Rebating or tonguing will be perhaps necessary when the skirting consists of more than one piece, that the different Skirtings

pieces may be made to fit neatly and firmly together; and all but the lowest piece must of necessity be brought to a width, as well as tried up in other particulars. A skirting in a single width is called by that term; but when it is made up of more than one part it is designated a base; the lowest board is then called the skirting board, and the upper the base moulding or mouldings (Plate XXVI. figs. 1 and 5). The skirting board is not brought to a width because the labour would be lost according to the ordinary mode of fixing it. The board is applied to its place with its lower edge touching the floor; but as the most perfectly wrought floors are found to have some slight unevenness of surface so close to the wall, a straight edge would not fit closely down to it in every part. The board is therefore propped up at one end or the other until the upper or faced edge is perfectly parallel with the average line of the floor, or rather so as to be perfectly level. A pair of strong compasses, such as are used by the carpenter, is taken, and opened to the greatest distance the lower edge of the skirting board is from the floor throughout its length; the outer edge near the point of one leg of the compasses is then drawn along the floor, whilst the point of the other, being kept vertically above it, is pressed against the face of the board, on which it marks a line exactly parallel to the surface of the floor, indicating, of course, every, even the slightest, irregularity there may be in it. If the floor be not a very uneven one, the excluded part may be ripped off with the hand or the panel saw, which may generally be made to follow the traced or inscribed line exactly; if, however, the line be a very irregular one, having quick turns in it, the hatchet must be used. This operation is called *scribing*, and the result of it is evidently to make the skirting fit down on the floor with the utmost precision. Care must be taken in performing the operation that the upper edges of the skirtings be not only level, but that all which are in immediate connection be scribed to the same height, that their upper edges may exactly correspond.

In the principal rooms of a house, the skirting C (fig. 91) is usually grooved into the floor D, and fixed only to the narrow piece *d*, called a ground. (See also Plate XXVI. fig. 5.) By fixing in this manner, the skirting covers the joint, which would otherwise soon be open by the shrinking of the back, and from the skirting being grooved into the floor, but not fastened to it, there cannot be an open joint between the skirting and floor. When it is considered that an open joint in such a situation must become a receptacle for dust and a harbour for insects, the importance of adopting this method of fixing a skirting will be apparent. As grooving a floor is attended with considerable labour, and as the boards will sometimes twist, it is more common now to nail a small fillet to the floor, against which the back of the skirting rests, and, of course, has full room for expansion. Before skirtings are fixed, vertical blocks are put at short intervals, extending from the floor to the narrow grounds, and made exactly flush with and true to the latter, and are firmly nailed. These form a sound backing, to which the skirtings may be bradded or nailed, and so prevented from warping or bending in any manner. If, however, the skirting be not very wide, and be sufficiently stout to stand without a backing, a fillet only is nailed along the floor as a stop for its lower edge; but this is rendered unnecessary if the skirting be tongued into the floor, as the tongue will answer every purpose of a stop (fig. 5, Plate XXVI.) The ends of skirtings should be tongued into each other when it is necessary to piece them in length; and on returns or angles the end of one should be tongued into the returned face of the other in the square parts, and mitred in the oblique-angled or moulded parts.

The dado of a room should be fixed in the same manner as explained above for window backs (fig. 91). When a chair-rail or surbase is required, grounds similar to those for the base are fixed to range like them with the face of the plastering; the surbase itself must be wide enough to cover the grounds and the joints formed by them and the plastering completely; it is in effect a cornice to the stereobate (or pedestal, as the three parts may be termed of base, dado, and surbase), and the space or dado between it and the base is generally understood to be wainscoted, though it is more frequently plastered.

Fixing large boards.

In fixing any board above 5 or 6 inches wide, similar precautions are necessary as those detailed in fig. 91, otherwise it is certain to split when the house becomes inhabited. We may, in general, either fix one edge and groove the other, so as to leave it at liberty, or fix it in the middle and leave both edges at liberty. Sometimes a wide board, or a piece consisting of several boards, may be fixed by means of buttons screwed to the back, which turn into grooves in the framing, bearers, or joists, to which it is to be fixed. If any shrinking takes place the buttons slide in the grooves. In this manner the landings of stairs are fixed, and it is much the best mode of fixing the top of a table to its frame.

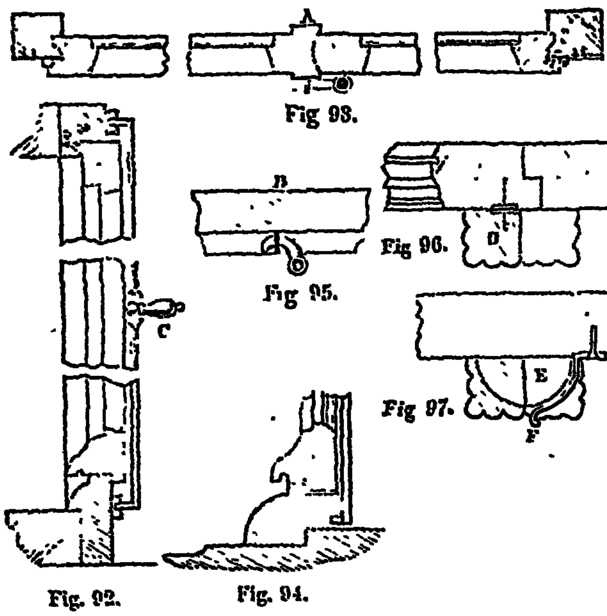
Sashes.

The parts of the outside frame of a sash are distinguished by the terms applied to the similar parts of common framing. The upright sides are styles, and the transverse or horizontal ones, which are tenoned into the ends of the styles, are rails; but the inner framework or divisions for the panes are called merely upright and cross bars (these bars, according to the way they are moulded, are called lamb's tongue, ovolo, beaded, &c.),—the upright being the mortised, and the cross bars the tenoned, as with the outer framework (Plate XXVI. fig. 1). Sashes are got out like common framing; the parts are tried up, set out, and mortised and tenoned, exactly in the same manner, allowance being made in the length of the rails and all tenoned pieces in the setting out, as in common framing also, for the portions of the mortised styles and upright bars which are worked away in forming the moulding and rebate. The meeting rails of sashes which are in pairs, to be hung with lines, are made thicker than the other parts by the thickness of the parting bead, and they are bevelled or splayed off, the one from above and the other from below, that they may meet and fit closely. When the framework is completed, although it cannot be put together because of what has just been referred to, the rebate is formed by the sash fillister on the further part of the face edge, and the moulding struck on its hither angle. These things being done, the moulded edges are either mitred or scribed at the shoulders and haunches, and the sash may be put together. If sash bars are mitred at the joints, they require dowels in the cross bars to act as tenons; but if they can be scribed, dowelling is not necessary. Sashes are either hung upon hinges or hung with lines, pulleys, and weights. Fixed sashes are put into frames, of which every part may be solid but the stop, which must be put in behind the sash to detain it. Sashes hung with hinges are usually called casements, and require solid rebated frames; but there can be no stops to them, except their own movable fastenings, and the outer stop, which of course the rebate furnishes.

French casements.

These are usually known as French casements, or sash doors, as they are called when they open down to the ground or floor; they have now taken the place of sash windows, where they may lead from the room to garden paving, or to a balcony, or may be used for similar purposes. The ordinary arrangement for an aperture is that of two leaves working on hinges at the sides inwards or outwards, meeting in the centre of the opening. With the former, which is the usual mode, one leaf is secured to the head and sill by bolts either round or sunk in; the other leaf, when closed, is secured to the first by a handle fixed on the second and turning over a staple fixed on the first. If the casement

should be a high one, this second leaf often requires a bolt at top and bottom, to secure it against the force of the wind, which by bending it admits the cold air and wet. When it is placed towards an exposed aspect, and is thus subject to driving rains, it is necessary to take many precautions for the prevention of wet being blown through the meeting surfaces all round the casements. To effect this object, the styles, rails, and frames are sunk and beaded in various ways. Figs. 92 and 93 represent sills and



FIGS. 92-97.—French Casement fittings.

bottom rails; and fig. 94, meeting rail, styles, and frame, which last is an ordinary arrangement in France. An improvement to the mere handle for securing the leaf of the casement is that of affixing an upright metal rod, which is turned by the handle C, fig. 92, on the leaf being closed, and by hooks at top and bottom as B, fig. 95, catching into a plate fixed for them, and effectually fastening it. A simpler method has been shown where, in lieu of the rod, a reeded bar, as D, fig 96, is moved to and fro as the leaf is required to be opened or shut, the top and bottom of the bar being rounded as shown at E, fig. 97, so as to slide into two segmental plates F, secured to the sill and lintel. Fig. 96 is a plan of the two casements, and 97 a plan of the head and sill. The metal rod, which is of brass, is called the Espagnolette bolt. Another mode of securing the casements has lately been introduced, whereby a flat plate, the whole height of the opening, is inserted in a groove formed in one edge of the meeting style of a leaf; and on this being closed the plate is shot forward by a handle into a groove in the other leaf, fastening the two together, the plate forming a stop against both the wind and the rain. This is a patent arrangement of Arch. Smith and Co. Fig. 98 is a plan of the usual French casement used at Paris. A shows the two leaves of the casement when shut; B is a plan of the shutters in their boxing, CC the shutters when closed, D the bolt, E the inside architrave and F the *Persiennes*, or outside blinds, shut against the stone reveals, and so provided for by the architect, instead of being an addition made by the upholsterer after the work is done, and perhaps spoiling the design. The ordinary mode is for them to be hung with projecting hinges to admit of their being folded back into the face of the wall, which is a hideous arrangement for any façade, except perhaps one of plain brickwork or plain cement. GG shows the position of the blinds when shut, and H is the outside architrave. Much difficulty arises in preventing the rain and wind from penetrating under such doors. The French raise the doors very much to secure this, as shown in figs. 92 and 94. In England various methods have been adopted by forming second sills of metal cast into shapes to form gutters and throats; perhaps the best arrangement is the "patent sill or water bar" (fig. 99), as now manufactured by Archibald Smith and Co. A metal plate A is screwed to the face of the bottom rail. An arrangement in metal B is screwed to the upper weathering of the wood sill C, having on its outer edge a plate D hinged to it. When the door is opened this plate falls down, and when the door or leaf is shut, a pin E, let into the underside of the bottom rail, forces up the hinged plate D, and presses it against the first named plate A, making all tight. Fig. 100 is a section of a mediæval moulded bottom rail found in France. When the window lights are carried up over the casements, as is very often the case, the upper lights are generally fixed; but it is better that one or two of them should be rendered available for ventilating the apartment when it is not desirable to have the door itself open. This will be effected by hinging the light on the bottom rail, with the necessary means of opening and closing it, or placing it on centre hinges at the sides.

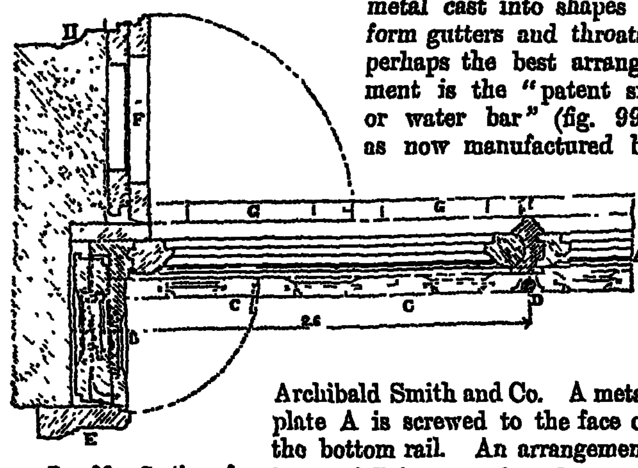


FIG. 98.—Section of French Window.

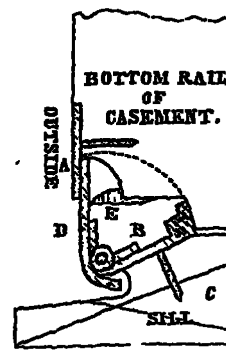

FIG. 99.—Water Bar.

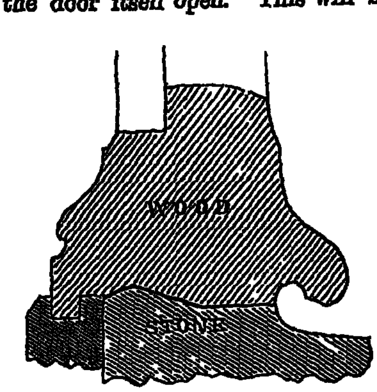

FIG. 100.—Ancient French Bottom Rail.

Sashes hung with lines require cased frames (Plate XXVI. figs. 1, 4), to receive the pulleys and weights. The sill of the frame is made, as in the former cases, solid, is sunk and weathered, and is generally made of a more durable material than the rest of the frame; the sides in the direction of the thickness of the frame are of one and a quarter or one and a half inch board, very truly tried up, and grooved to receive a parting bead; for it must be obvious that sashes hung with lines to run vertically up and down within the height of the frame must be themselves in two heights, and must pass each other in separate and distinct channels. The ends of these boards are fixed into the upper face of the solid sill below, and into a similar board parallel to the sill which forms a head above, and they are called pulley pieces, or styles, because they receive the pulleys, which are let into them near their upper ends.

Linings from 4 to 6 inches in width, and from three-fourths of an inch to an inch in thickness, are nailed on to the edges of the pulley pieces, and to the sill and head above and below, inside and outside, in the direction of the breadth of the sash frame, and are returned along the head in the direction of its length. The outside linings are made to extend within the pulley pieces about half an inch, to form a stop for the upper and outer sash; and the inside linings are made exactly flush with their inner faces. The casing is completed by fixing thin linings on the outer edges of the outside and inside linings, parallel to the pulley pieces, to prevent anything from impeding the weights. Thin slips called parting-beads are fitted tightly into the grooves previously noticed in the pulley pieces, but they are not fixed, as the upper sash can be put in or taken out only by the temporary removal of the parting-bead. An inner or stop bead is mitred round on the inside to complete the groove or channel for the lower sash; the stop bead covers the edge of the inside linings on the sides and head, and is fixed by means of screws, which may be removed without violence when it is required to put in or take out the sashes. A hole covered with a movable piece large enough to allow the lead or iron weight to pass in and out, is made in each of the pulley pieces, so that the sashes may be hung after the frames are set, and to repair any accident that may occur to the hangings in after use (Plate XXVI. fig. 4). It may be remarked that sash frames require greater truth and precision from the workman than anything else in the joiners' work of a building; and unless the stuff employed be quite sound and perfectly seasoned all the workman's care will be thrown away.

Sashes, it may be remarked, are never fitted until these frames are immovably fixed, so that if there be any inaccuracy in the latter, the sashes are cut away or pieced out to make them fit; but, as they are intended to traverse, the fitting in that case can only apply to one particular position, and in every one but that there must be something wrong. Any incorrectness in the sash-frame, again, must throw the shutters and their back flaps out; indeed, the sash-frame, though apparently a secondary part of the arrangement, is that which affects all the rest beyond anything else. When sashes have been fitted, a plough groove, wide and deep enough to receive the sash-line, is made in the outer edges of the styles, for about two-thirds of their length, at their upper ends. They are then primed and glazed, and when the putty is sufficiently set the joiner hangs them. He is furnished with sash-line, which is made of the best flax well plaited together, tacks, and iron or lead weights, which are generally made cylindrical, with a ring at one end, to which the line may be attached. A sash is weighed, and two weights are selected which together amount to within a few ounces of a counterpoise. The line is then passed through the pulley, which was previously fixed in the pulley style; the end is knotted to a weight which is passed in at the hole left for the purpose; and at a sufficient distance, which a common degree of intelligence will readily determine, the line is cut off and the end tacked into the groove in the style of the sash. Other modes of attaching the sash-line to the sash are also used.

Of recent inventions connected with windows there are some for enabling the parting-beads to be taken out, or are dispensed with, so that sashes may be readily cleaned without the operator standing on the sill, a dangerous practice, and without the use of the glazier's horse, which tends to injure the inside painting. A contrivance for easily opening and closing sashes of large size by an arrangement of cords and pulleys, which likewise secure it when shut, is patented by Mr Meakin. Another, having counterbalancing rack slips for hanging sashes, dispenses with the use of sash lines, pulleys, and sash weights. An objection to this invention may be that both upper and lower sashes must be opened at the same time. There are other useful arrangements for opening windows, such as those used in the wards of hospitals, where the opening is divided into about four horizontal lights working on pivots, all opening to any required extent by a rack and pinion. A sash fastener with a second spring, which clips the projection on the lower sash when the fastening is closed, and another where the shape of the arm of the fastener is altered, both prevent the sash being opened from without by a knife, a common mode of forcing an entrance into buildings. Patent wrought windows, and patent wrought iron water-tight windows and frames suitable for churches, parsonage houses, &c., are readily obtainable.

Window fittings.

The fittings of a window which has boxed shutters consist of back linings, grounds, back elbows and soffit, together with shutters and back flaps, and architraves (or pilasters) round on the inside to form a moulded frame (figs. 1 and 4, Plate XXVI.) Back linings are generally framed with flush panels; they fit in between the inside lining of the sash frame and the framed ground, to both of which they are attached, and form the back of the boxing into which the shutters fall back. They are tongued into the inside lining by their inner edge, and on the outer edge the ground is nailed, and they are set at right angles to the sash-frame, or obtusely outwards, as the shutters may be splayed or not. The back is the continuation of the window fittings from the sash-sill to the floor on the inside; the elbows are its returns on both sides under the shutters, and the soffit is the piece of framing which extends from one side of the window to the other across the head, or from back lining to back lining. These are all framed to correspond with the shutters on the face; but, as they are fixed, their backs are left unwrought. Window shutters are framed in correspondence with the door and other framed work of the room to which they belong, in front, and generally with a flush panel behind; the back-flaps are in one or two separate breadths to each shutter, according to the width of the window and the depth of the recess; they are made lighter than the shutters themselves, and they should, when shut to, present faces exactly corresponding with those of the shutters, both internally and externally. The shutters are hung to the sash-frame with butt hinges, and the back flaps are hung to their outer styles with a hinge called a back-flap, from its use. The shutters and their back flaps are hung in one, two, or more heights, as may be found convenient. The moulded margin round the boxings of a window on the inner face are made to harmonize generally with the similar parts of the doors of the room or place to which it belongs. See other examples of shutters and their boxing in fig. 98. The fixing and hanging of window fittings or dressings are hardly less important, for the accuracy required, than the making and fixing of the sash-frame itself; the slightest infirmity or inaccuracy in any part will be likely to derange some essential operation.

Shutters.

Rolling shutters.

To this old manner of forming shutters must be added the rolling shutters of Clark, Bunnett, Francis, Snoxell, and others. These can be fixed either at the top, bottom, or side of the window as convenient, and are made of wood, steel, iron, or of wood and iron, many of them requiring machinery to raise and to lower them. The advantages consist in the small space occupied, the great security obtained, and the rapidity and ease in opening and shutting them. They are, however, apt to stick, and some are noisy, but one is called the "noiseless self-coiling revolving steel shutter." One variety consists in a sheet of well-tempered corrugated steel, which coils up on itself like a roll of paper; another is a self-acting wood revolving shutter, with hardened steel bands.

Stairs. The construction of stairs is generally considered the highest department of the art of joinery. The principal object to be attended to is that the stairs should afford a safe and easy communication between floors at different levels. The strength of a stair ought to be apparent as well as real, in order that those who ascend it may feel conscious of safety. To make the communication safe, it should be guarded by a railing of proper height and strength; in order that it may be easy, the rise and width (or tread) of the steps should be regular and justly proportioned to each other, with convenient landings; there should be no winding steps, and the top of the rail should be of a convenient height for the hand. The first person that attempted to fix the relation between the height and width of a step, upon correct principles, was, we believe, Blondel, in his *Cours d'Architecture*. His formula is applicable to very large buildings, but not to ordinary dwellings. Mr Ashpitel, who investigated the subject at length, gives the following rules for buildings of seven different classes:—

Tread breadth in inches.	Rise height in inches.	Tread breadth in inches.	Rise height in inches.
12	5½	10	6½
11½	5¾	9½	6¾
11	6	9	7
10½	6¼		

These dimensions give angles of ascent varying from 24° to 37°. Of course the projection of the nosing is not reckoned.

Hawksley's patent treads for staircases to public thoroughfares are composed of iron frames, in which small blocks of wood, placed the end way of the grain, are so secured as to present to the foot a roughened surface. They appear to be durable, and to admit of easy renewal of the wood when worn or injured.

The forms of staircases are various, commencing with a straight flight, which should only be used to a low story. In towns, where space cannot be allowed for convenient forms, they are often made triangular, circular, or elliptical, with winding steps, or are made of a mixed form, with straight sides and circular ends. In large mansions, and in other situations where convenience and beauty are the chief objects of attention, winding steps are never introduced when it is possible to avoid them. Good stairs, therefore, require less geometrical skill than those of an inferior character. The best architectural effect is produced by rectangular staircases, with ornamented railing and newels. In Gothic structures scarcely any other kind can be adopted with propriety for a principal staircase. Modern architecture admits of greater latitude in this respect,—the end of the staircase being sometimes circular, and the hand-rail continued, beginning from either a scroll or a newel.

When a rectangular staircase has a continued rail, it is necessary that it should be curved so as to change gradually from a level to an inclined direction. This curvature is called the *ramp* of the rail. The plan of a staircase of this kind is represented by ABCD in fig. 101; and fig. 103 shows a section of it, supposing it to be cut through at *a b*, on the plan. The hand-rail is supposed to begin with a newel at the bottom, and the form of the cap of the newel ought to be determined so that it will mitre with the hand-rail. Let H in fig. 102 be the section of the hand-rail, and *a b* the radius of the newel; then the form of the cap may be traced at C. The sections of hand-rails are of various shapes; some of the most common ones are too small; a hand-rail should never be less than would require a square of which the side is 2½ inches to circumscribe it. For the level landings of a staircase the height of the top of the hand-rail should never be more than about 40 inches, and in any part of the inclined rail the height of its upper side above the middle of the width of the step should be 40 inches less the rise of one step when measured in a vertical direction. To describe the ramps, let *r s* in fig. 103 be a vertical line drawn through the middle of the width of the step; set *r u* equal to *r s*, and draw *u t* at right angles with the back of the rail, cutting the horizontal line *s t* in *t*; then from the point *t*, as a centre, describe the curve of the rail. When there is a contrary flexure, as in the case before us, the method of describing the lesser curve is the same.

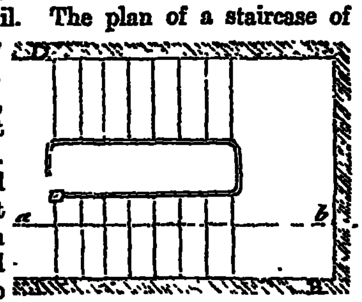

Fig. 101.—Plan of Rectangular Staircase.

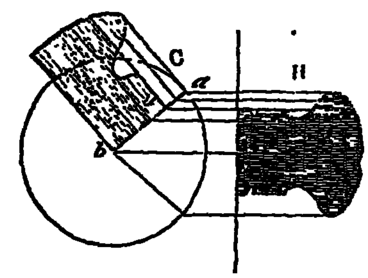

Fig. 102.—Section of Hand-Rail and Newel.

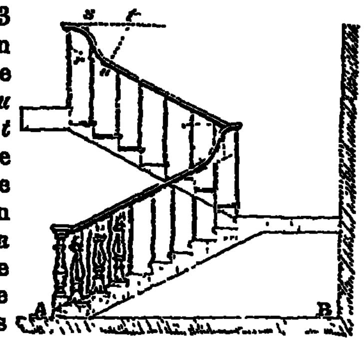

Fig. 103.—Section for Construction of Ramps.

The hand-rail of a stair generally begins with a scroll, and the first step of the stair is generally finished with what is called a curtail, a form corresponding closely to the scroll. There are a great variety of geometrical spirals; but as they all finish on a point, and as all architectural scrolls and volutes finish on a circle or eye, the usual mathematical scrolls are inapplicable. The earliest spiral adapted to architecture was that of De Lorme. Since his time several systems have been invented, particularly that of Goldmann; the best is that derived from the Ionic volute (fig. 104).

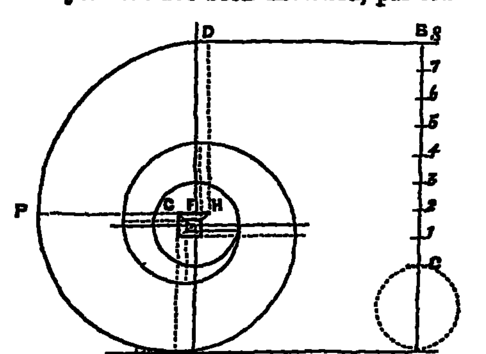

Fig. 104.

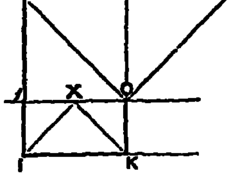

Fig. 105.

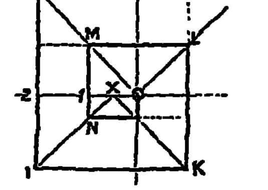

Fig. 106.

Figs. 104 to 106 illustrate the construction of the Ionic Volute.

The height, eye, and number of revolutions of the

spiral being given to describe the curve, let AB be the total height, and AC the intended height of the eye, and let the spiral be required to make two revolutions. Divide BC into four times as many parts as there are revolutions required ($4 \times 2 = 8$), because there are four quadrants in every revolution. Draw any line DE equal to the height of the spiral. Set down from D half the number of the parts and one more ($4 + 1 = 5$); this is the top of the eye. Set down half AC at O, and describe the eye; then at O set up half a part to F, and make FG, FH = OF; then, as in fig 105, draw OG, OH, GI, and from O draw a line parallel to GH, and divide the same into as many parts as there are to be revolutions. Fig. 105 is for one, and fig. 106 for two revolutions. Bisect O1 at X; make 2I = 2X, and join XI; and through 1 draw MN parallel to OF to meet OG and XI. Draw the quarter circles, as in the diagram,—HD being the first opening of the compasses, GP the next, and H, G, I, K, L, M, and N being the centres. To describe the scroll let AB, as in fig. 107, be the width across, usually about 10 or 12 inches; let EB be the intended diameter of the eye; and let the scroll be required to make one revolution and a half, or six quadrants (these are shown at greater size by the side of fig. 108), then proceed as last directed, and complete the scroll, also dot in the lines of the nosings and risers. For the curtail step transfer the lines of nosings *a*, and the lines of the risers *b*, to another place, as in fig. 108, and set out the thickness of the veneer within the line of nosing, the part within this represents the solid block of the curtail. The places of the balusters are shown in fig. 107.

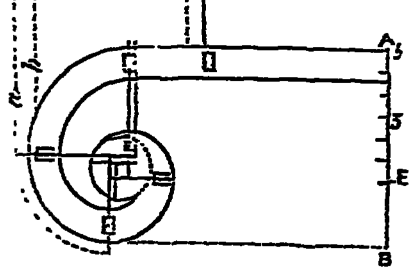

Fig. 107.

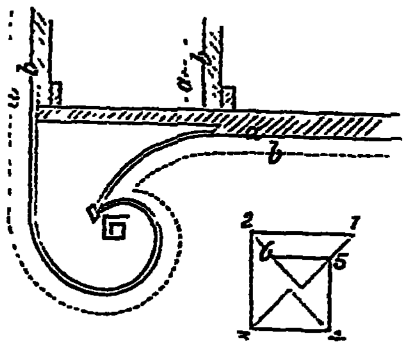

Fig. 108.

Figs. 107, 108 illustrate the formation of Scroll and Curtail Step.

It is obvious that in every geometrical staircase, the half of a cylinder placed upright in the well-hole would touch the wreathed string in all parts, another a little less would touch all parts of the hand-rail. Let us suppose ACB, as in fig. 109, to be the plan of half a cylinder so set upright in the well-hole, and let us suppose A'E to be the height of the same. Divide the curved line ACB into any convenient number of parts, and set the same off by compasses on the straight line from C to A' and C to B'. Or, in case ACB is a semicircle, divide the line AB, draw the diameter CD, making aD equal to three-fourths of the radius, and draw DA, DB, and the rest of the lines through the points of division, as shown in the diagram. Then A'B' is the stretch out or length of the circumference ACB unrolled. But A'E is said to be the whole height. From E set down the respective heights of the winders, step by step, as shown. Now let G be the representation of the cylinder, with the different lines squared up and across, these will give a representation of the curve at which the winders must ascend, and which, of course, must regulate the hand-rail. The other faint lines show the edge of the covering.

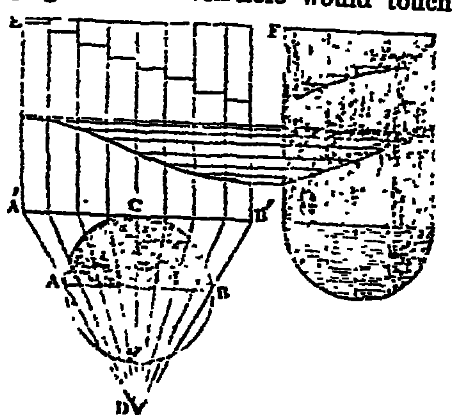

Fig. 109.—Construction of Hand-Rail.

Fig. 112 represents the plan of a staircase, beginning with a scroll, and having steps winding round the circular part of the well-hole. In the first place, let the end of the steps be developed according to the method we have just given (fig. 110 shows this development). Now the hand-rail ought to follow the inclination of a line drawn to touch the nosings of the steps, except where there is an abrupt transition from the rake of the winding to that of the other steps; at such places it must be curved,—the curve may be drawn by the help of intersecting lines, as in fig. 111. The part which is shaded in fig. 109 represents the hand-rail and ends of the steps when spread out, and the hand-rail is only drawn close to the steps for convenience, as it would require too much space to raise it to its proper position. This development of the rail is called the falling-mould. We will now refer to fig. 113, and will suppose the inner semicircle of ACB to be the plan of the well-hole, and *e*A, *a*B, the width of the rail; then the outer shaded part ACB will be the plan of the rail on the level; ADEB is the cylinder referred to before—ADE being the angle at which the stairs ascend. Now since by the principles of Conic Sections the oblique section of a circular cylinder is an ellipse, if the cylinder be circular the lines may then be found by a trammel. Be it of what section it may, the delineation of a cylinder cut at any angle ADE may be found by dividing it into equal parts, and setting up the ordinates *a*1, *b*2, &c., as shown. This delineation is a plan "on the oblique," or the face-mould of the rail, to be cut "on the plumb."

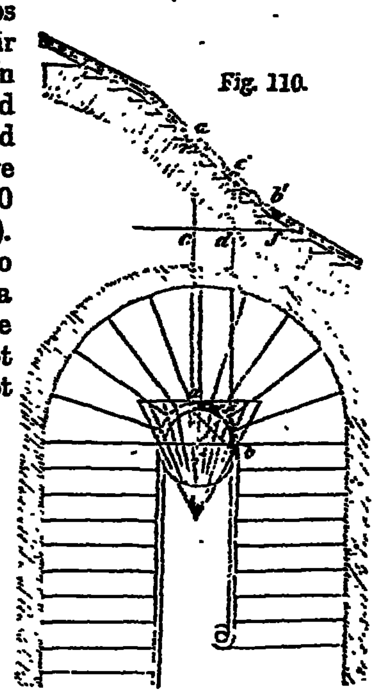

Fig. 110.

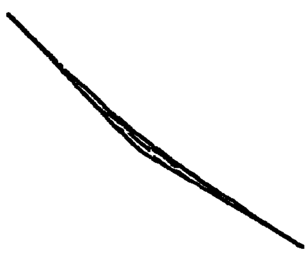

Fig. 111.

Fig. 112.

Figs. 110–112.—Development of Circular Hand-Rail.

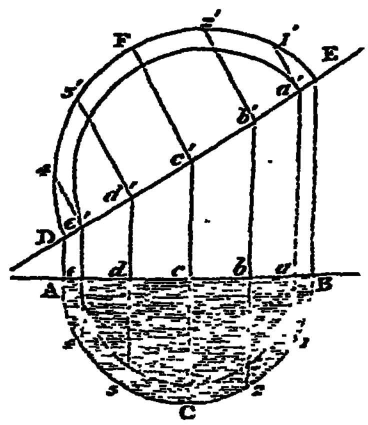

Fig. 113.—Tracing the Face-Mould of Rail.

The wood used for hand-rails being of an expensive kind, it becomes of some importance to consider how the plank may be cut so as to require the least quantity of material for the curved part of the rail. Now, if we were

to suppose the rail executed, and a plain board laid upon the upper side of it, the board would touch the rail at three points; and a plank laid in the same position as the board would be that out of which the rail could be cut with the least waste of material. Let it be required to find the moulds for the part $a\,b$ of the rail in fig. 112, and to avoid confusing the lines in the small figure, the part $a\,b$ has been drawn to a larger scale in fig. 114. The plain board mentioned above would touch the rail at the points marked C and B in the plan; draw the line CB, and draw a line parallel to CB, so as to touch the curve at the point E. Then E is the other point on the plan; and a', c', and b', are the heights of these points in the development in fig. 110. Erect perpendiculars to CB, from the points C, E, and B (fig. 114), and set off Ca' in fig. 114 equal to $a'c$ in fig. 110, Ec' equal to $d\,c'$, and Bb' equal to $f\,b'$. Through the points C and E, draw the dotted line Ch; through a', c', draw a line to meet CE in h; and through the points a', b', draw a line to meet CB in g; then join $h\,g$, and make Ci perpendicular to $h\,g$. Now, if Cd be equal to Ca, and perpendicular to Ci, and $d\,i$ be joined, it will be the angle which the plank makes with the horizontal plane, or plan. Therefore, draw FD parallel to Ci, and thence find the section, which is the same thing as would be obtained by projecting vertical lines from each point in the hand-rail against the surface of a board laid to touch it in three points. The inexperienced workman will be much assisted in applying the moulds if he acquires a clear notion of the position when executed.

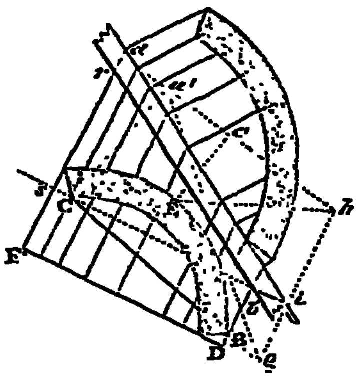

FIG. 114.—Illustrating the Tracing of Moulds.

To find the thickness of the plank, take the height to the under side of the rail $c\,r$ in the development (fig. 110), and set it off from s, in the line Ci, to r, in fig. 114; from the point r draw a line parallel to $d\,i$, and the distance between those parallel lines will be the thickness of the plank. The mould (fig. 114), which is traced from the plan, is called the *face mould*. It is applied to the upper surface of the plank, which being marked, a bevel should be set to the angle $i\,d$ C, and this bevel being applied to the edge will give the points to which the mould must be placed to mark out the under side. It is then to be sawn out, and wrought true to the mould. In applying the bevel, care should be taken to let its stock be parallel to the line $d\,i$, if the plank should not be sufficiently wide for $d\,i$ to be its arris. In the method fig. 113, ADE, on the rise of the stair, is the bevel. After the rail is truly wrought to the face-mould, the falling-mould (fig. 110), being applied to its convex side, will give the edge of the upper surface and the surface itself will be formed by squaring from the convex side, holding the stock of the square always so that it would be vertical if the rail were in its proper situation. The lower surface is to be parallel to the upper one. The sudden change of the width of the ends of the steps causes the soffit line to have a broken or irregular appearance; to avoid this, the steps are made to begin to wind before the curved part begins. Different methods of proportioning the ends of the steps are given by Nicholson, Roubo, Rondelet, and Krafft. We cannot in this place enter into a detail of these methods, nor can we give the varied systems of cutting the rail in the spring and in the plumb, about which so much has been written, but for the reader's information a list of the principal writers on *Staircases and Hand-Railing* is subjoined.

Nothing appears to have been written on joinery until Joseph Moxon, a fellow of the Royal Society, published a work entitled *Mechanick Exercises, or the Doctrine of Handyworks*, 4to, 1677. The introduction of the geometrical staircase, or stair supported on one side by the wall, invented, says Palladio, by the famous Luigi Cornaro (the first English example of which is said to be that erected in stone by Sir Christopher Wren in St Paul's Cathedral), led to the greatest changes in the art of joinery, inasmuch as the lines for setting them out necessitated a very considerable knowledge of geometry. The hand-rails of these stairs offered most difficulties, and an imperfect attempt to remove them was first made by Halfpenny, in his *Art of Sound Building*, published in 1725. Price, the author of the *British Carpenter*, published in 1733-35, was more successful, and his remarks show a considerable degree of knowledge of the true nature and object of his researches. The publication of this book must have produced a considerable sensation in the trade, for it was soon followed by many other works of different degrees of merit. Of these the publications of Langley and of Pain were the most popular, and were followed by Roubo, *L'Art de Menuisier*, folio, 1771; Skaife, *Key to Civil Architecture*, 8vo, 1774; *Transactions of the Society of Arts*, &c., for 1814; *Treatise on the Construction of Staircases and Hand-Rails*, 4to, 1820; Rondelet, *Traité de l'Art de bâtir*, tom. iv. 4to, 1814; Krafft, *Traité sur l'Art de la Charpentier*, part ii., folio, 1820; Jeakes, *Orthogonal System of Hand-Railing*, 1849; Ashpitel, *On Hand-Rails and Staircases*, 4to, 1851; Galpin, *Joiner's Instructor, Staircasing and Hand-Railing*, 4to, 1853; and Riddell, *Hand-Railing Simplified*, folio, Philadelphia, 1856 and 1860. Bibliography

The establishment of the principles of joinery on the sound basis of geometrical science was reserved for Nicholson. In his *Carpenter's New Guide* and *Carpenter and Joiner's Assistant*, published in 1792, 4to, he has made some most valuable corrections and additions to the labours of his predecessors. This writer has been the founder of all the subsequent works on the subject; his books have been published again and again, in various forms, with additions from time to time, by different hands, as Galpin's *Joiner's Own Book, showing Improvements since the Days of the late Mr Nicholson*, 4to, 1856. Corresponding improvements were also made in the practice of joinery, for which we are much indebted to an architect, Mr James Wyatt.

For revived mediæval and Elizabethan joinery, particularly as adapted to windows and staircases, see Weale's *Carpentry*, 4to, 1849, and Shaw, *Details of Elizabethan Architecture*, 4to, 1839. Many modern improvements are given in Laxton's *Examples of Building Construction*, fol., 1855-58, and in Newland's *Carpenter and Joiner's Assistant*, fol., Liverpool, 1860.

The principles of joinery were cultivated in France by a very different class of writers. The celebrated Blondel, an architect of great eminence, had given details for the construction of shutters, wainscoting, doors, hinges, fastenings, &c., in his work *Distribution des Maisons de Plaisance*, 4to, 1737-38. In the extensive work of Frezier, entitled *Coupé des Pierres et des Bois*, 3 vols. 4to, 1739, all the leading principles are given and explained with tedious minuteness, offering a striking contrast to the brevity of English writers. The first elementary work on that part of geometrical science which contains the principles of joinery appeared in France in 1705, from the pen of the celebrated Gaspard Monge, who gave it the name of *Géométrie Descriptive*. The most celebrated French work which treats of joinery is Rondelet's *L'Art de bâtir*, which occupied fourteen years (from 1802 to 1816) in publication. It is also the best foreign work on the subject; but it is little adapted to the state of joinery in England. In practice the French joiners are very much inferior to the English workmen. Their work is rough, slovenly, and often clumsy, and at the best is confined to external effect. The neatness, soundness, and accuracy, which is common to every part of the works of an English joiner, is scarcely to be found in any part of the works of a French one. The little correspondence, in point of excellence, between their theory and practice leads us to think that their theoretical knowledge is confined to architects, engineers, &c., instead of being diffused among workmen, as it is in England. See also Thiollet et Roux, *Nouveau Recueil de Menuiserie*, 1837; Viollet-le-Duc, *Dict. Raisonné du Mobilier Français*, 8vo, 1858, &c.; and Nosban, *Manuel de Menuiserie*, 4to, 1849. Much also may be learned from Emy, *Traité de la Charpente*, fol., 1847—particularly with regard to framing. The publications of other nations do not call for particular notice.

CABINET-MAKING.

Cabinet-making, or that part of the art of working in wood which is applied to furniture, has some affinity with joinery, the same materials and tools being employed in

Laying slates.

which is employed in plain tiling. To a roof with projecting eaves a wide board is placed over the ends of the rafters; but when the eaves tail into gutters, the gutter-board is made wide enough to receive the eaves-course For light slating it is necessary to board a roof all over with three-quarter inch rough boarding. This is done by the carpenter; but for strong heavy slates, fillets or laths or battens are considered sufficient; and these are laid by the slater himself, to suit the length of his slates. Three inches wide and one inch thick is a sufficient size for them, if the rafters be not more than 12 inches apart. Against gable or party-walls, a feather-edged board called a tilting fillet is laid to turn the water from the wall. A preferable plan, however, is to board all roofs; it gives a better bed for the slates, and fewer are broken if there be occasion for workmen to walk over them in repairing or in cleaning out the gutters. The expense, too, is but trifling beyond that of the laths. A still further benefit is obtained by bedding the slates in mortar or in hay, which fills up the spaces left by the thickness of the first slate, and with the boarding tends to keep the roof cooler in summer and warmer in winter, a very desirable result for the habitable rooms close under them. Where the roofs are finished with diagonal boarding on purlins without rafters, it makes a very sound bedding for slates. All the slates being gauged to a width, and dressed as above described, and sorted in lengths, they are then taken up to the roof in rotation, beginning with the longest and largest for the lowest courses. The first course the slater lays is little more than half the length of that which is intended to cover it, and is necessary to break the joints at the eaves. This is called the doubling eaves-course; and the covering eaves-course is brought to the same foot line, completely to cover it. Then to ascertain the gauge:—from the length of the slate deduct the bond, which should never be less than 2 inches, and need not be more than 3½ inches, and the half of what remains will be the gauge. Thus, if the bond be fixed at 3 inches, and the slate is 2 feet 3 inches in length, the gauge will be 1 foot. This gauge or margin is set up from the foot of the eaves-course at each end, and a line strained to mark it along the whole length, and so on, to the ridge or top, where another half-course is required to complete the work, and that is in its turn secured by a covering of sheet lead with a roll. To a hipped roof care is taken to complete every course up to the angle, by cutting slates to fit its slope; and these are also covered by an overlap of sheet lead with a roll, it being nailed or screwed to the hip rafter, and the head bossed over. Slate ridging with a roll, as fig. 115, or with a groove for receiving an ornamented cresting, is now very usual, and even a common ridge tiling is necessary to prevent theft of the lead in some localities. Fig. 116 shows specimens of the ornamental red ridging tiles occasionally used, continuously or some lengths of a plain tile apart. In fig. 115, A, A are the two portions of the slate roll ridging, B being the roll with a hole drilled at each end for the insertion of a pin to fix the lengths; C the ridge piece fixed in the head of the king-post D; E the rafter; F the lath on which G, the slating, is nailed. In nailing a slate, it must not be strained or bent in the slightest degree, or it will certainly fly in some sudden atmospheric change, to which it is of course constantly liable, even if it escape fracture from being trodden on by the workmen themselves or by others. Copper, being less liable to oxidize from exposure to common causes than any other metal that will answer the purpose, should always be used for slate nails. Zinc is also occasionally used; and iron tinned and painted nails are sometimes substituted by dishonesty on the part of the workman or builder, or bad economy on that of the proprietor. The French method of fixing slates by means of wire clips which hold the bottom of the slates is unusual in England. A method has lately been introduced of effecting it with lead clips, which is said to dispense with a certain proportion of slates. Each slate is held in something of the same manner which the slater now adopts when a broken slate has to be replaced, and the main advantage is supposed to be that the slates are firmer.

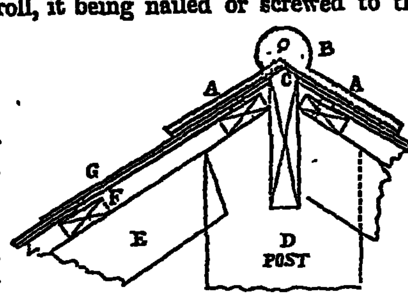

FIG. 115.—*Ridge of Roof.*

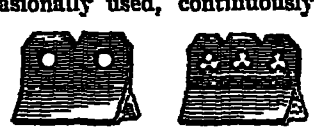

FIG. 116.—*Ridging Tiles.*

The mode above described of ascertaining the gauge or margin by the bond, is equally applicable to every sort of roof-covering that is made up of small inflexible parallelogramic slabs or tablets; and it should be borne in mind that the greater the angle is at which the rafters rise, or, in technical language, the higher the pitch of the roof, the less the bond may be, and *vice versa.* With slabs or tablets that vary in length, too, as slates generally do as they are brought to market, it is the bond which it is of importance to observe; but if they are of an invariable length, as tiles are, it is sufficient that the gauge or margin be attended to.

Patent slating.

A very light and neat covering is produced by laying wide slates side by side, and covering their joints with narrow slips bedded in putty, the overlap at the ends being no more than the bond is with the usual mode. It is known as patent slating, and was introduced by Mr Wyatt, who never, however, obtained a patent for it. Indeed it is in principle the mode which was adopted in ancient Greece in covering the roofs of temples. Neither boards nor fillets are used, the slates bearing from rafter to rafter, which may be 2 feet or more apart, and to the rafters the slates are screwed. The covering slips are also screwed, as well as bedded in putty. Slating of this kind may be laid at no greater elevation than 10°, whereas for slating in the ordinary way the angle should never be much less than 25°, though large slates with a 3½ inch bond, carefully laid and pointed, may perhaps be trusted at a rise of 20°. This mode of applying slate is not without the disadvantage attending the fixing of any substance that freely takes up and readily parts with heat. In expanding and contracting, the joints are too often destroyed, and leaks are the common consequence.

Thatching.

Thatching is an admirable covering for securing warmth in winter and coolness in summer; but it is subject to injury by birds, and to risk from fire. It is still occasionally used in picturesque cottages, arbours, and similar buildings, and was much used for churches in Norfolk and Suffolk. The thatcher requires a common stable fork, to toss up the straw together before being made into bundles; a thatcher's fork, to carry the straw from the heap up to the roof; a thatcher's rake, to comb down the straw straight and smooth; a knife, or eaves knife, to cut and trim the straw to a straight line; a knife, to point the twigs; a half glove of leather, to protect the hand when driving in the smaller twigs or spars; a long flat needle; a pair of leather gaiters to come up above the knees, used when kneeling on the rafters; and a gritstone to sharpen the knives. Wheat straw lasts from 15 to 20 years, and oat straw about 8 years. Reed thatching, as done in the West

of England, is the truss after the ears have been cut off, leaving the clean, sound pipe straw, of which a thickness of 3 inches is laid on the common thatching with spars only. The materials required are straw or reeds, laths, nails, withes, and rods. A load of straw, laid on about 12 to 16 inches in thickness, will do a square and a half; a bundle of oak laths, $1\frac{1}{4}$ inches wide, and from $\frac{1}{4}$ to $\frac{3}{8}$ths thick, nailed about 8 inches apart, 1 square; a hundred of withes, 3 squares; a pound of rope yarn, 1 square; a hundred of rods, 3 squares; and $2\frac{1}{2}$ hundred of nails, 1 square. Probably thatched roofs were formerly ornamented by a species of cresting, for in some parts of the country the withes or willow twigs that bind the thatch are sometimes arranged on the tops of ricks and cottages in an interlacing manner, terminating at the apex or at each end with a spike with a rudely formed cock. Viollet-le-Duc, in his *Dictionnaire*, alludes to the custom of forming the ridge in mud, in which plants and grasses were inserted to prevent the earth being dissolved and washed away by the rain.

Plumber-work.

Lead, as the name imports, is the material in and with which the plumber works. The principal operations of this trade are directed to the covering of roofs and flats, laying gutters, covering hips, ridges, and valleys, fixing water trunks, making cisterns and reservoirs, and laying on the requisite pipes and cocks to them, fixing water-closet apparatus, setting up pumps, and applying indeed all the hydraulic machinery required in economic building. The plumber's tools are knives, chisels, and gouges for cutting and trimming, rasps or files and planes for fitting and jointing, a dressing and flatting tool for the purposes its name expresses, iron hammers and wooden mallets for driving and fixing, ladles in which to melt solder, grozing irons to assist in soldering, a hand-grate or stove which may be conveniently moved from place to place for melting solder and heating the grozing irons, a stock and bits for boring holes, and a rule of two feet in length divided into three parts, two of boxwood, the third of steel, for passing into places he may have to examine; also compasses, lines, and chalk for setting out and marking, and centre-bits of all sizes for making perforations, together with weighing apparatus, as the quantities of most of the materials used by the plumber must be either proved or determined by weight. The waste of lead in working is very trifling, as cuttings all go to the melting pot again with little or no loss but that of refounding or casting; and even old lead is taken by the lead merchant in exchange for new at a very trifling allowance for tare and the cost of reworking. A plumber is always attended by a labourer, who does the more laborious work of carrying the materials from place to place, helps to move them when necessary, melts the solder and heats the grozing irons, attends to hold the one or the other, as neither may be set down or put out of hand when in use, and assists in some of the minor and coarser in the temperature of the atmosphere. It may be taken, indeed, as a general rule, that solder should be dispensed with as much as possible. Like glue to the joiner, it is indispensable in many cases; but like glue also, it is in common practice made to cover many defects, and much bad work, that ought not to exist. The soft solder used by plumbers on account of its melting easily is a composition of tin and lead in equal parts, fused together, and run into moulds in shape not unlike the bars of a gridiron. In the operation of soldering, the surfaces of the metal intended to be joined are scraped and rendered very clean; they are then brought close together, and sprinkled with resin or borax at the joints to prevent oxidation while soldering. The heated solder is then brought in a ladle and poured on the joint, and smoothed and finished by a hot grozing iron and rubbed down with a cloth.

Sheet lead, whether cast or milled, is supplied of various weight or thickness, and is always described as of such weight (4 to 12 pounds) to the superficial foot. There are very few purposes, indeed, in building, in which lead of less than 6 ℔ to the foot should be used, and very few in which the weight needs to exceed 10. For roofs, flats, and gutters, under ordinary circumstances, 7 or 8 ℔ lead is a very fair and sufficient average; for hips and ridges, lead of 6 ℔ to the foot is thick enough; and for flashings 5 ℔ lead need not be objected to. Cast lead has been preferred for the former purposes, because its surface is harder, but milled lead is of more even thickness throughout, bends without cracking, which is not always the case with cast lead, and makes neater work. Sheets of cast lead run from 16 to 18 feet long and 6 feet wide; milled sheets are made of about the same width, and 6 or 8 feet longer than cast sheets. Neither the one nor the other may be safely used on flats, or in gutters exposed to the wide range of temperature of our climate, in pieces of more than half the length and half the breadth of a sheet; that is to say, from 8 to 12 feet long, and 3 feet wide, are the limits within which sheet lead will expand and contract without puckering and cracking; and to allow it to move freely it is laid with rolls and drips in such a manner that any extent of surface may be covered with the effect of continuity, though the pieces of lead forming the covering be of such small sizes as above stated. But all *fixing*, whether by soldering or otherwise, is to be carefully avoided. A roll is a piece of wood made about 2 inches thick and $2\frac{1}{2}$ inches wide, rounded on one edge, and fixed with that edge uppermost, so as to come 4 inches within half the width of a sheet, that the edges may be turned up and folded round and over it, being lapped by, or lapping the edge of the adjoining sheet (Plate XXVI. fig. 7). Lead sufficiently stout, dressed neatly and closely down to the boards under it, and over the rolls at its edges, will require no fastening of any kind, unless it be so light as to be movable by the wind. Rolls are used mostly in roofs and flats; drips principally in gutters, though they may be required in long flats. The drip is formed in the first instance by the carpenter in laying the gutter boards, according to an arrangement with the plumber. It is a difference made in the height of the gutter of from $1\frac{1}{2}$ inches to 3 inches, where one sheet terminates in length, and meets another in continuation. The end of the lower is turned up against the drip, and that of the upper is dressed down over it, so as effectually to prevent the water from driving up under it. Where the fall is not great, a piece should be cut out across the higher gutter board, so that the top of the under-lead may lie level with the board. Gutters should have a fall of at least an eighth of an inch to the foot, and in flats it should be rather more, for such a covering is only so called in contradistinction to the pitch of a roof; ends and sides which are against a wall should

Sheet lead. Cast and milled. Rolls. Gutters.

turn up against it from 5 to 7 inches, according to circumstances; and the turning up under the slates, tiles, or other roof covering, to a gutter, should be to the level of that against the wall at the least. The turning up against the wall should be covered by a flashing. This is a piece of lead let into one of the joints of the wall above the edge of the gutter lead, and dressed neatly down over it, to prevent water from getting in behind it (Plate XXVI. fig. 6). Parallel or box-gutters are necessary next parapets where a curb roof is formed, and are useful in valleys of small roofs where the depth for it can be obtained. Fig. 117 is a section of such a gutter next to a parapet wall, in which A is the wall plate; B the tie-beam of the roof; C a bearer for carrying one end of the gutter bearer D, the other end being tenoned into the pole plate K; E the gutter boards carried by its bearers; G the lead gutter, laid in somewhat of an oval shape by the small angle fillets, which are useful in preventing the lead being returned at a right angle, where it is sometimes cracked in laying; H the flashing; I the eaves' board for raising the last row of slates, over which the lead is fixed; L the common rafter; M the slating; N the principal rafter forming part of the truss of the roof; O the saddle-back coping of the wall, throated on both sides. Where thick walls could be obtained, it was usual to form this sort of gutter below the timbers of the roof, whereby they were kept dry, and damage from the overflowing of the gutter prevented. The same result is occasionally achieved by a cornice projecting more than usual, the gutter being formed on it in place of a real blocking course. If the gutters and flats are to be often walked upon, they should be protected by deal lattice work raised on fillets but not fixed. Snow falling down the slopes is prevented by this from stopping the gutters, and it also lessens the action of the sun upon the lead-work. Lead on ridges and hips and the top and sides of dormers, not being in sufficient masses to be secured by its own weight, must be fastened by nails bossed over.

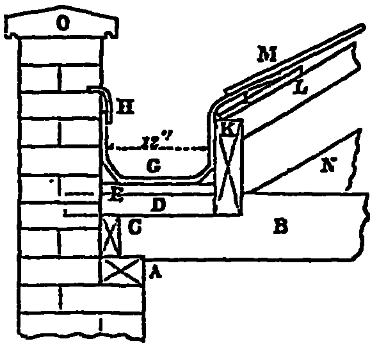

Fig. 117.—Gutter and Roof-Timbers.

s
pes. In making cisterns and reservoirs, unless they be cast (and these are now disused), the sheets of lead must of necessity be joined by soldering; but the water they are intended to contain protects the lead from the frequent and sudden changes to which in other and more exposed situations it is exposed. The lead-work forms a lining to a wood case, which has grooved and tongued sides and a bottom. But cisterns are now commonly made of zinc, or of galvanized iron, or of slate; the last two do not require a casing, but may perhaps be enclosed in a closet. Service or water pipes to and from the cisterns, as also waste or overflow pipes, are also made of lead, and described by their bore, as $\frac{1}{2}$ in., $\frac{3}{4}$ in., inch, and so on. They are generally supported and attached to the wall by means of iron boldfasts. Iron water pipes are fixed where lead will probably be stolen. The opinion that some waters are injured by coming in contact with the lead of cisterns and pipes, has led to the formation of pipes of tin encased in lead. The water companies are now requiring a water regulator to be put to each closet, or a water waste preventor where the constant supply is obtained, but these are a very troublesome addition to the plumber's work, on account of the difficulty of keeping them in working order. The constant supply system requires taps of a different construction from those used in other cases; these are called "screw down valves," from their action, and resist the pressure of the water. As repairs must occasionally be needed to the main pipes, it is recommended that, to prevent inconvenience, one or more cisterns be always provided in the house for containing two days' supply of water.

Rain-water trunks and pipes are made of a certain number of pounds weight to the yard in length, according to the bore or calibre that is required. The pipes are fitted with large case heads above, to receive the water from the gutter spouts, and with shoes to deliver the water below; they are fixed or attached to the walls of buildings of stone usually with flanges of lead, which are secured by means of spike nails,—iron and other metals having superseded lead where brick is used or economy requires the substitution.

The varieties of water-closet apparatus, of which Underhay's patent is one of the best, are too numerous to be here described. Pumps of all kinds and powers are amongst the other matters coming within the plumber's province, together with cocks, bosses, ferules, washers. valves, balls, grates, traps, funnels, service boxes, and a numerous collection of other articles.

A metal occasionally used for roofs in lieu of lead is known by the name of Wetterstedt's patent marine metal. It is composed of lead and antimony. Its advantages are its malleability, great tenacity, elasticity, and durability, and its resistance to acids, oxidation, and the action of the sun and atmosphere. It is manufactured in sheets of certain sizes, from 3 lb to 8 ounces per foot, according to the purposes for which it is required, the latter weight being useful for lining damp walls. It should be secured with wrought copper nails. A patent metallic canvas is also manufactured of various substances and strength, serving for waterproof and secure covering. Patent marine metal.

Sheet copper was formerly used on account of its lightness to cover roofs and flats. The thickness generally varied from 12 to 18 ounces per square foot. It was laid like lead, but the plates being of small size were soldered together. It will be well to notice that water collected from copper channels must not be used for culinary purposes, as a film of verdigris is formed, which is poisonous. Copper is much used for roofing in foreign countries. Copper roofing.

Lead and copper, where economy is required, are superseded by zinc, which is not only much cheaper, but when good is nearly as durable, and is not so liable to be corrugated by the action of the sun. Zinc is subject to oxidation; but the oxide, instead of scaling off as that of iron does, forms a permanent coating on the metal. Its expansion and contraction are greater than those of any other metal. Zinc sheets as manufactured vary in quality, some being very brittle. That supplied by the Vielle Montagne Zinc Mining Company possesses a high reputation for purity and excellence. Zinc must be laid like lead, without fixing either by nails or solder. No. 13 gauge, weighing 19 oz. 10 drs., is the least for roofs, flats, and gutters on boarding. No. 14, a medium thickness, weighing 21 oz. 13 drs., is used for roofs and flats; and No. 15 or 16, weighing 24 oz. and 26 oz. 3 drs. per foot superficial, for best work and roofs without boards. Zinc pipes are extensively used as chimney pots; stamped and moulded ornamental zinc for dormers, Mansard roofs, vanes, guttering, and rain-water pipes, cisterns, &c.; and perforated zinc for blinds and for ventilation. Zinc roofs

Tin cannot class with the building materials in England, although it is extensively used for covering roofs in America and in Russia. Tin roofing.

The best publications on this trade are the makers' price books and lists of articles made and sold by them. See also the article METALLURGY.

Plaster-work.

No art in the economy of building contributes more to produce internal neatness and elegance, and no one is less absolutely important, so far as the use and stability of a structure are concerned, than that of the plasterer. The very general application of plaster is of comparatively late date; for wainscoted walls, and boarded or boarded and canvased ceilings, or naked joists alone, are frequently found in houses of rather over a century old, both in England and on the Continent; and a return to this state of completion in the present day is the result of the attempts of the mediæval school of architects, and their cry of "no shams," which has not been quite successful among themselves, for plaster and cement are used by many. The walls of houses were formerly plastered above the wainscoting and coloured, while the ornamented plaster ceilings of the time of Henry VIII., Elizabeth, and James I., are still the admiration of lovers of the art. Still earlier specimens of the plasterer's skill are extant in the pargetted and ornamented fronts of half-timber houses.

For the more common operations of plastering comparatively few tools and few materials are required. The plasterer is attended by a labourer, who supplies his boards with mortar, and by a boy on the scaffold with him to feed his hawk, which is a piece of wood about 10 inches square with a handle under it, for carrying up small portions of plastering mortar to the wall or ceiling, to be there delivered and spread by the trowel, a thin plate of hardened iron or steel with a wooden handle, similar to that used by the bricklayer. The plasterer is obliged to keep this implement particularly clean and dry when he is not actually using it, lest it rust in the slightest degree, as it is clear that the brown oxide of iron would sadly discolour his finer work on touching it againwith the trowel. He is necessarily furnished with a lathing hammer, a hand float, a quirk float, and a derby or darby, which is a long two-handled float for forming the floated coat of lime and hair; brushes for fine or rough work; three or four jointing trowels for mitres, &c.; jointing rules; moulds for cornices, which are of wood, but for work of any importance the frame is made of wood and the outline cut out of a copper (or more usually zinc) plate,—these are inserted in the wooden stock, and narrow pieces of wood are fixed to the moulds transversely to guide and steady them along the screeds; a straight edge, wherewith to bring the plastering on a wall or ceiling to a perfectly even surface by traversing it in every direction; a screen, having metal wires to act as a sieve for separating the coarser materials which enter into the composition of plastering mortar,—these are thrown against its outer face, to separate the particles which are too large for the purpose from the finer,—the sand and lime, too, are mixed much more efficiently and completely by screening them together than in any other manner; a spade and hod like those of the bricklayer's labourer; a rake to separate the hair used in the mortar and distribute it throughout the mass; and a server for the hawk boy to beat up the mortar, and to deliver it in small pats on the hawk.

terials. The plasterer, as the term imports, works in plastic, adhesive compositions, which are laid on walls, both internally and externally, to stop crevices, reduce inequalities, and produce an even, delicate surface, capable of receiving any decoration that may be applied to it, either in colour or otherwise. These compositions are as various as the modes of applying them, the rudest being a compost of loam, a marly clay, and lime; this is used only for the commonest purposes, and being laid on in one coat, is washed over with a thin mixture of lime and water, a process termed lime-whiting. There are many grades from this to the highest work of the plasterer,—the making imitations of marbles and other costly stones, from the purest calcined gypsum mixed with a solution of gum and isinglass and colouring matter to produce the required imitation. His materials are laths, lath nails, lime, sand, hair, and plaster, a variety of stuccoes and cements, together with various ingredients to form colouring washes, &c. Scaffolding is not Scaff generally required for new work, but with old work it is sometimes necessary. Under ordinary circumstances, the plasterer is enabled to wash, stop, and whiten the ceilings and walls of rooms from trestles, with boards laid across them. In lofty saloons and halls, churches, &c., scaffolding is indispensable. It is necessary, too, to a front that is to be plastered in any way; but this may be afterwards washed, repaired, and coloured from a ladder, without the intervention of a scaffold, except perhaps the suspended scaffold now so much used.

Laths are narrow strips of some straight-grained wood, Lath generally of fir, though oak laths are sometimes used, in lengths of 3 and 4 feet, or to suit the distances at which the joists of a floor or the quarterings of a partition are set, and in thickness from $\frac{1}{8}$th to $\frac{3}{8}$ths of an inch; those of the greater thickness are called lath and a half. Lath nails are either wrought or cut; cut nails are in common use in England with fir laths. Coarse stuff is composed of ox Coar or horse hair from the hide, in addition to lime and sand stuff. mortar; this is intended to act as a sort of mesh to net or tie it together, and form a coarse but plastic felt. The hair should be long, and free from all grease and filth. Road drift is unfit to be used in place of clean sharp sand in mortar, unless it be completely cleansed from all animal and vegetable matter, and of mud and clay. Fine stuff is made of fine white lime, exceedingly well Fine slaked with water, or rather macerated in water to make the slaking complete; for some purposes a small quantity of hair is mixed up with this material. The mere paste, when allowed to evaporate until it is of a sufficient consistence for working, is called putty. Gauge stuff is composed of Gaug about three-fourths of putty and one-fourth of calcined stuff. gypsum or plaster of Paris; this may be mixed only in small quantities at a time, as the plaster or gauge renders it liable to set very rapidly. Bastard stucco is made of Stucc two-thirds fine stuff, without hair, and one-third of very fine and perfectly clean sand. Common stucco is composed of about three-fourths of clean sharp sand and one-fourth of the best lime, well incorporated. This must be protected from the air from the time it is made up until it is required to be laid on the walls. Parker's (or Parker's Roman) cement, when of good quality, with fine clean sharp sand, Ceme in the proportion of about three of sand to one of cement, and well executed, forms a very good external coating for walls. It is vulgarly called "comps," a contraction of "composition." Portland cement, so called because the mortar formed by it when mixed with sand is supposed to present the appearance of stone from the Portland quarries, is in much esteem for an outside stucco, as the colour to which it dries is sufficiently agreeable to the eye without any colouring wash, whereas Parker's cement is too often of a dark dirty tint, requiring painting or colouring to render it tolerable. Portland cement is also much valued as being proof against water when used as a mortar in setting brick-work, and in the composition of concrete for foundations. The patent selenitic cement already described (page 459), is stated to be an excellent substitute for Portland cement; it takes double the usual quantity of sand, and is stronger even then than ordinary mortar. Plastering is finished in much less time than by the common mode.

A class of cements capable of taking a brilliant polish resembling marble, and consequently very suitable for internal decoration, deserves to be mentioned. The chief

of these are Keene's marble cement and Parian cement. They become excessively hard in a short time, and are capable of being painted in a few days. The principal component is said to be obtained by the precipitation of alum by an alkali, which gives a white powder of great brilliancy. Tints can be made up with these cements for coloured decorative work. Cements made by the mixture of oil with various substances were formerly much used both here and abroad. The best known in England was called Hamelin's mastic, that in France the mastic de Dhil. These cements being very expensive, and requiring to be constantly painted, have now gone nearly out of use. For outside plastering they form a very fine clean surface, as may be seen in the quadrant in Regent Street and other buildings of that date, but in many instances it has been taken off and Portland cement substituted.

Blue lias lime.

Blue lias lime was formerly greatly esteemed as a cement for outside work, but the carelessness of the burners has tended much to limit its use, there being a large proportion of underburnt stone left in it. The workmen also would not take the requisite pains for slaking this lime, and manufacturers therefore ground it, by which operation the core becomes mixed up with the properly burnt material, and the efficiency of the lime is destroyed. The lumps should be broken as small as nutmegs, then immersed in water on a sieve until air-bubbles freely rise to the surface; the lime so wetted is to be left in a heap covered by damp sand for twenty-four hours, after which time it should be screened and mixed with the proper quantity of sand and the least possible quantity of water. To one of lime may be put not more than from two to two and a half of sand. When slaked it does not increase in bulk.

Coats of plastering.

The various coatings of plastering are distinguished thus. On laths, plastering in one coat simply is said to be laid, and in two coats, laid and set. In three-coat plastering on laths, however, the first is called the pricking up, the second is said to be floated, and the third set. On brick or stone walls, plastering in one plain coat is termed rendering; with two coats, a wall is said to be rendered and set; and in three, rendered, floated, and set.

Lathing ceilings.

Before beginning to lath a ceiling, the plasterer proves the under face of the joists, to which he has to work, by applying a long straight edge, and makes up for any slight inequalities in them, when the work is not to be of a very superior description, by nailing on laths or slips to bring them as nearly even as he can. When the inequalities are great, or if the work is to be of fine quality, he recurs to the carpenter, who takes off inordinate projections with his adze, and nails on properly dressed slips where the joists do not come down low enough, and thus brings the whole to a perfect level. This operation is called firring, or furring. If it be a framed floor with ceiling joists the plaster has to work to, it is tolerably sure to be straight; but the carpenter must have firred down on the beams or binders to the level of the ceiling joists, unless the ceiling joists have been nailed to the beams or binders, when nothing of this kind is necessary. If a ceiling is to be divided into compartments or panels, the projecting or depending portions must be bracketed or cradled down to receive the laths. It is an important point to be attended to in plastering on laths, and in ceilings particularly, that the laths should be attached to as small a surface of timber as possible, because the plastering is not supported or upborne by its adhesion or attachment to the wood, but by the keying of the mortar itself, which passes through between the laths, and bends round over them. If then the laths are in constantly recurring contact with thick joists and beams, the keying is as constantly intercepted, and the plastering in all such places must depend entirely on the portions between them which are properly keyed. Under a single floor, therefore, in which the joists are necessarily thick, a narrow fillet should be nailed along the middle under the whole length of them all, to receive the laths and keep them at a sufficient distance from the timber to allow the plastering to key under it; thus too the surface may be made more perfectly even, as it is in single floors that inequalities mostly occur. This being all arranged, the plasterer commences lathing. The laths should be of the stronger sort. Thin weak laths, if used in a ceiling, are sure to produce inequalities, by sagging with or yielding to the weight attached to them; one or two weak ones in a ceiling of otherwise strong laths may be the ruin of the best piece of work. They should be previously sorted, the weak, crooked, and knotty, if there be such, being reserved for inferior works, and the best and straightest selected for the work of most importance, so that the workman shall find none to his hand that is not fit to be brought in. Taking a lath that will reach across three or four openings, he strikes a nail into it on one of the intermediate joists, at about three-eighths of an inch from the one before it, and then secures the ends of that and the one that it meets of the last row with one nail, leaving the other end of the lath he has just set to be secured in the same manner with that which shall meet it of the next bay in continuation. It is of importance also that in ceiling-work he pay attention to the bonding of his work. In lathing on quartering partitions and battened walls, the bonding is not a matter of much importance; nor is the thickness of the timbers behind the latter of so much consequence as in a ceiling, because the toothing which the thickness of the lath itself affords to the plastering is enough to support it vertically; but, nevertheless, the more complete the keying, even in works of this kind, the better, as the toothing above will not protect it from any exciting cause to fall forwards, or away from the laths. The thinner or weaker sort of lath is generally considered sufficiently strong for partitions.

When the lathing is completed, the work is either laid or pricked up, according as it is to be finished with one, two, or three coats. *Laying* is a tolerably thick coat of coarse stuff or lime and hair brought to a tolerably even surface with the trowel only; for this the mortar must be well tempered, and of moderate consistence,—thin or moist enough to pass readily through between the laths, and bend with its own weight over them, and at the same time stiff enough to leave no danger that it will fall apart,—a contingency, however, that in practice frequently occurs in consequence of badly composed or badly tempered mortar, unduly close lathing, or sufficient force not having been used with properly consistent mortar to force it through and form keys. If the work is to be of two coats, that is, laid and set, when the laying is sufficiently dry, it is roughly swept with a birch broom to roughen its surface, and then the set, a thin coat of fine stuff, is put on. This is done with the common trowel alone, or only assisted by a wetted hog's bristle brush, which the workman uses with his left hand to strike over the surface of the set, while he presses and smoothes it with the trowel in his right. If the laid work should have become very dry, it must be slightly moistened before the set is put on, or the latter, in shrinking, will crack and fall away. This is generally done by sprinkling or throwing the water over the surface from the brush. For floated or three-coat work, the first, or pricking up, is roughly laid on the laths, the principal object being to make the keying complete, and form a layer of mortar on the laths to which the next coat may attach itself. It must, of course, be kept of tolerably equal thickness throughout, and should stand about one-quarter or three-eighths of an inch on the surface of the laths. When it is finished, and while the mortar is still quite moist, the plasterer scratches or scores it all over

ith the end of a lath in parallel lines from 3 to 4 inches art. The scorings should be made as deep as possible thout laying bare the laths; and the rougher their ges are the better, as the object is to produce a surface which the next coat will readily attach itself. When e pricked up coat is so dry as not to yield to pressure in e slightest degree, preparations may be made for the ating. Ledges or margins of lime and hair, about 6 or inches in width, and extending across the whole breadth a ceiling or height of a wall or partition, must be made the angles or at the borders, and at distances of about 4 t apart throughout the whole extent; these must be de perfectly straight with one another, and be proved every way by the application of straight edges; techni-ly these ledges are termed *screeds*. The screeds are gauges the rest of the work; for when they are ready, and the rtar in them is a little set, the interspaces are filled up sh with them; and a derby float or long straight edge ng made to traverse the screeds, all the stuff that projects yond the line is struck off, and thus the whole is brought a straight and perfectly even surface. To perfect the rk, the screeds on ceilings should be levelled, and on lls and partitions plumbed. When the floating is suffi-ntly set and nearly dry, it is brushed with a birch broom before described, and the third coat or set is put on. is for a fine ceiling that is to be whitened or coloured st be of putty; but if it is to be papered, which is very usual, ordinary fine stuff, with a little hair in it, will be ter. Walls and partitions that are to be papered are of this latter, or of rough stucco, but for paint the set st be bastard stucco trowelled. This coat must be ked of exactly the same thickness throughout, to pre-ve to the external surface the advantage that has been ained by floating. For all but the last-mentioned, the on floated work, the trowel and brush are considered icient to produce fine and even work; but trowelled cco must moreover be hand floated. In this operation stucco is set with the trowel in the usual manner, and ught to an even surface with that tool to the extent of or three yards. The workman then takes the hand-t in his right hand, and rubs it smartly over the surface, sing gently to condense the material as much as pos-e. As he works the float he sprinkles the surface with er from the brush in his left hand, and eventually duces a texture as fine and smooth almost as that of ished marble.

But lathing and plastering on laths as practised in gland is at best a very flimsy affair, and greatly uires improvement. Stronger laths than the laths nmonly employed, put on further apart, and with headed ught nails, and the plastering laid on upon both s in upright work, or both above and below the ceilings he same time, two men working against one another, l produce work in some degree worthy of the name. practice of the French in this respect is well worthy consideration, and to a great extent the imitation, of ...

work behind it, and be incorporated with it as much as possible. As its name imports, its surface may, indeed should, be rough; but it is not scratched or lined as the similar coat on lath is. For this, too, the wall must be previously wetted, that the mortar may the better attach itself to it. For the floating, screeds must be formed as before described, and the consecutive process is exactly the same as on lath, both for the floated and for the set coat. In almost every case in which plastering is to be floated, the workman finds a guide for the feet of his wall screeds in the narrow grounds which the joiner has previously fixed for his skirtings; from these he plumbs upwards, and makes his work perfectly flush with them.

Mouldings and cornices.

Mouldings and cornices (as large combinations of mouldings and flat surfaces immediately under the ceilings of rooms are called) are formed with running moulds, and are generally executed before the setting coat is put on the walls and ceiling. If the cornice do not project more than about an inch and a half, or 2 inches, from the ordinary work, a backing of lime and hair will be sufficient; and if any one part only happen to be more than ordinarily protuberant, a row of nails from 6 to 12 inches apart stuck into the wall or ceiling in the line of that part will give it sufficient support. But if the general mass of the cornice be more than that amounts to, and extend more than 6 or 8 inches along the ceiling, it must be bracketed out, and the bracketing lathed and pricked up, as for ordinary work. This pricking up, or other preparation, must of course be perfectly set before the cornice is run; and there should be one-fourth of an inch at least of clear space between the preparation and the mould in the nearest part. A wooden screed or parallel straight edge is tacked on with brads to the wall, and another on the ceiling, if the cornice be large and heavy, as guides or gauges for the mould, whose rests are chased to fit them; and then one man laying on gauge stuff in an almost fluid state with an angular trowel, another works the mould backwards and forwards over it, which strikes off what is superfluous, and gives the converse of its form to the rest. The mould is never taken down from the work at right angles to the line of it, but is drawn off at the end, so that none of the parts of the moulding or cornice is injured or torn by it, which must otherwise frequently be the case, from the peculiar forms at times given to the details. If a cornice be too large and heavy to be executed at once, it may be done in the same manner at two or more times, in so many parts; and if any part or parts of a moulding or cornice is to be enriched, the space for it is left vacant by the mould, and the enrichment is afterwards supplied. As a cornice cannot be completed up to the angles by the mould, it is worked by hand in those situations to a joint. The joinings are termed mitres, and in forming them the plasterer uses the jointing tools we have already described.

Enrichments.

Models for enrichments are made by the modeller, according to the design or drawing submitted to him, and from them the plasterer makes wax or gelatine moulds, or, as in ordinary practice, the modeller supplies the moulds in which the ornament is cast in plaster of Paris. If the ornament be in recurring lengths or parts, as is usually the case, only one length or part is modelled, and casts of as many as are required are taken from the mould; some single ornaments, again, which are very large, require to be moulded and cast in parts, which are put together by means of cement. When the cast ornaments are sufficiently dry the pieces are scraped and trimmed, and the joints made clean and even; and they are set in the cornice with plaster of Paris, with white lead, or with a composition called iron cement, as the case may require. If the castings have something in the cornice to rest upon, the first will do; but if there is nothing to retain or attach them but the

cement, one of the last two must be used. Flowers and other ornaments on ceilings which are too large and heavy to be trusted to adhesive matter alone, must be screwed to wooden cradling behind and above them.

Plastering with stucco. In plastering a wall with common stucco (and its use is mostly for outside work), the first thing to be done is to remove the dust from it by brushing, and then to wet very completely with water. If the wall to be stuccoed be an old one, or one of which the joints have been drawn, the mortar of the joints must be chipped or even raked out, and the bricks picked, to expose a new and porous surface to the plastering before brushing and wetting. The wall is then covered with stucco in a fluid state, applied with a broad and strong hog's bristle brush, like common white-washing. When this is nearly dry the stucco must be laid on as in common rendering, unless the work is to be floated, when the process is nearly similar to that in floated plastering. Screeds must be formed at the highest and lowest extremities of the wall, or of that part of the wall which is in the same vertical line, and is not intercepted by string courses, and be returned at the angles, putting the whole surface into a sort of frame. These must be made perfectly straight and plumb, so as to be quite out of winding by the careful application of the plumb-rule and straight edge. Inner vertical screeds must then follow at three or four feet apart across the whole surface, and be made to range exactly with the outer ones, and then the interstices must be filled in as before. As the work is made good it must be well rubbed with the hand float, as in the execution of trowelled stucco internally, to compress the material, and produce a hard, even, and glossy surface. Preparations for cornices and other projections from the straight surface of the work must have been previously made in or on the brick or stone-work by the protrusion of bricks, tiles, or whatever may be best suited to form a core; and the mouldings and cornices are run with moulds, in the manner described for the same things internally, only that in work of this kind no plastic material but the stucco itself is used,—that is, there is no preparation of any softer material than the stucco itself put under it. In running cornices in this material, workmen are very apt to mix a little plaster of Paris with the stucco to make it set under the mould, and thus give sharpness and fulness to the mouldings; but this should not be permitted; for the plaster is not qualified to stand the weather as the stucco is, and, if mixed with it, will produce premature decay. When the stucco is perfectly dry, it may be painted in oil colours, or be coloured in distemper; and in either case it is generally (though not invariably) ruled over the surface with a lead point, to give it the appearance of gauged stone-work.

Outside cement-work. Rendering in the Roman and Portland cements is executed almost exactly in the same manner as stucco rendering is, only that it is laid on the saturated wall directly, without the preliminary operation of roughing in, or washing the surface with a solution of the material. The same process, too, is followed in floating this cement, and with the same exceptions; and as, in addition to its superior hardness and capacity for duration, it is a quick-setting cement, it is far preferable to any of the common stuccoes for running cornices, mouldings, &c. These cements may, like stucco, be painted in oil, or coloured; but instead of a size colour, which is used for almost every other purpose in plastering, the colour for this composition is mixed with diluted sulphuric acid. This too may be lined and tinted to imitate stone and stone-work of any description.

Decay of stuccoes and cements. It may not be amiss here to refer to some of the causes of the premature decay which takes place in stuccoes and cements when used externally as a coating to walls. The primary cause is the presence of muddy earth and decayed animal and vegetable matter in the sand used with the lime and cement. To this may be added frequent impurities in the limes and cements themselves, particularly of argillaceous matter in the former, and sometimes the too great proportions of lime or cement to sand. These things might, however, remain quiescent for a long time, if the work were well protected from access of moisture, which is the grand exciting cause. The paint, or distemper wash, on the surface, is generally sufficient to prevent the rain which may beat against a vertical face from penetrating, especially if the work have been well hand-floated and trowelled, to make it close and compact; but the evil arises from exposure above, and from the numberless horizontal unfloated surfaces which are constantly presented. These receive and collect the water, and convey in streams over the vertical surfaces what is not immediately absorbed; and the work thus becoming saturated, frost seizes and bursts it, or warmth calls the vegetative powers of the impurities in it into action, and the whole is covered with a green sward. Let the sand of which a plaster composition is to be formed, whether with lime or cement, be washed until it no longer discolours clean water, and be well compounded with cementitious matter free from impurities with which it is so frequently charged; let the work be well hand-floated and trowelled, particularly on the backs or upper horizontal surfaces of projections, and protected above by projecting eaves or otherwise; and the work, with common care and attention to paint or distemper at intervals, will last as long as anything of the kind can be expected, or is found, to last anywhere.

Rough-cast. A cheap and useful covering for external walls, which are protected by projecting eaves, in plain buildings, is rough cast. This is executed in the following manner:—The surface is first roughed, or indented, and then well brushed with a stiff brush to remove all dust or loose earth. It is then covered with the rough cast, which consists of a small quantity of mortar diluted with water, to which a trowel of pure lime is added to make it about the thickness of cream. After the workman has done all within his reach the scaffolding is lowered, and he proceeds with the remainder. Another process is somewhat dearer. After having been roughed or indented, the wall is sprinkled with water, and then rendered with lime and hair; and when that is set, another coat of the same material is superadded, laid as evenly as it can be without floating, and as soon as a piece of two or three yards in extent is executed, the workman lays on it an almost fluid mixture of clean fine gravel and strong lime, which have been well mixed together. This is immediately washed with any ochreous colour that may be desired, and the whole dries into one compact mass. A third process, called stuccoing, is performed by the workman laying on a few trowels of stucco, which he spreads as much as possible; a second workman provided with a brush and a small wood float follows him, and after sprinkling the mortar with water he rubs over that part he has wetted with the float, and at the same time it may be whitened with lime alone. When the lime is very good this makes very good work.

Repairs. In renovating and repairing plastering the whole surface is first well washed to remove the dirt which may have attached itself, and as much of the earthy matter of the previous coat of whitening or colouring as will come away; any injuries the work may have received, such as cracks and fractures, are then repaired; and when the new stuff is quite dry, the joinings are scraped to produce an even surface, and the whole is again whitened or coloured once or twice or oftener as may be required, to make it bear out well. Stuccoed walls which have been painted must

be well rubbed with pumice stone, to take off the old paint as much as possible before the new work is proceeded with.

d ring. For a decoration to rooms having plastered walls, instead of papering or flat painting, or for a suitable ornamentation for the interior of churches built at small outlay, the old system of pargetting has been revived. The usual stucco or other plaster finish is, while still wet, stamped over with a pattern made of brass, or for rougher work of wood, to any geometrical or other form in accordance with the style of architecture; this indents the surface. It may be left all of one colour, or the open portions of the device may be filled in with another coloured plaster.

ito. Another revived method, especially for outside work, now much in use is called sgraffito. It was in vogue with the Italian artists about two centuries since, who executed some very elaborate specimens of ornamentation with it. The process is briefly as follows:—First, mix with the mortar some colouring substance of the tint desired for the pattern of the design; then apply a thin coat of it to the wall. When this coat is nearly dry, apply on it another coat similarly prepared but of the colour intended for the grounding, and then, a mould having been prepared in zinc of the exact outline of the pattern, it is to be applied to the surface, its outer edge marked round, and with a sharp tool as much of the upper coat of plaster is cut away as comes within the pattern, down to the face of the lower coat. By a careful arrangement of pattern, a considerable variety of colouring may be employed; and even three coloured coats can be put on, cutting through sometimes one, sometimes two, as may be desired to represent the design. As the colour is in the material itself, there is no fear of its scaling and so presenting a bad appearance; and it is a comparatively cheap process for the decoration of a new surface which cannot be painted for some time. The process has been adopted in England with coloured cements for outside work.

Under the plasterer's trade it may be desirable to mention some of the varieties of artificial marbles, scagliola, and other similar work for the decoration of buildings.

liola. Scagliola is a species of plaster or stucco invented about 1600–50 in Italy. The work is lathed and plastered as usual, and then the artist commences, preparing his material, which is composed of the purest gypsum broken into small pieces and calcined, passed through a very fine sieve and mixed up with glue, isinglass, &c. In this solution the colours are diffused that are required to be imitated in the marble; or the colours are prepared separately, and afterwards mingled and combined nearly in the same manner that a painter mixes the primitive colours on his palette to compose his different tints. When the gypsum is prepared and mingled, it is laid on the plaster, and then floated with proper moulds of wood, the artists during the floating using the colours necessary for the imitation, by which means they become mingled and incorporated with the surface. The process of polishing follows, first by means of pumice stone, then with tripoli and charcoal and fine and soft linen; after this the surface is rubbed with a piece of felt dipped in a mixture of oil and tripoli, and last of all with pure oil. The imitation may be so good that except by fracture or by sound it cannot be discovered to be a counterfeit.

er tation bles. Marezzo marble is made of cement mixed with fibre for strength and to resist a blow. Slabs are bedded on plaster of Paris, and with cramps and dowels like marble. Every variety of marble can be imitated in it, and it receives a high and permanent polish. The Marbre Universel Company have put forward a new manufacture of a similar description.

Modelling, Carved Work, and Gilding.

The modeller copies the drawings of the designs which may have been prepared for the enrichments, in whatever material they are to be cast, whether in plaster, in metals, or in composition of any kind, for the plasterer, smith, or decorator. The model is made of soft wood, by the usual chisels and gouges, or in a finely-tempered and plastic clay called modelling clay, or in wax. The modeller works the clay with his fingers, assisted by a few ivory, bone, or steel tools for finishing off neatly and sharply, and for working in parts which he cannot reach with his fingers. The best workman is one who can do most towards producing the required forms with his fingers, unassisted by artificial tools, as a greater degree of ease and freedom almost always results from the use of the hands alone. The model being completed, it is moulded, that is, a mould or moulds are made from it of a preparation of resin or of gelatine, sometimes of plaster of Paris; the moulds, if they have to be formed in portions, are fitted exactly to each other at the edges, and in these moulds casts in plaster of Paris or other material are made to any extent that may be required. For smith's work the wood model is sent to the founder for casting in metal. For carved work, such as caps of columns, shields, medallions, consoles, &c., the model may be sent to the mason or stone carver for the completion of the block, which may have been left in a boasted state by the mason when setting it. Mode

The modeller having some pretensions to be considered an artist rather than a mere artificer, is for the most part paid according to his merits, rather than for so much time, according to the ordinary mode of determining the value of artificers' works.

The carver is strictly an independent artist, whose business it is to cut ornaments and enrichments in solid and durable material, such as stone and wood, so that, like the modeller, he must be paid according to the taste and power he may exhibit in his works, rather than as a common artificer. The art of carving has, however, been in a great measure superseded by modelling and casting. In works of a free style, or of a mediæval character, the carver is often left free to exercise his own taste and fancy or talents in the execution, with or without a sketch by the architect before him. The decorator, in addition to casts in plaster of Paris, now makes use of composition ornaments, which are formed of a mixture of whiting and glue pressed into moulds; or of papier mâché, which is paper pressed into moulds; or of a composition of a thin coat of plaster of Paris poured into the mould, and then covered with coarse canvas, the result being to all appearance a plaster cast, but it is far lighter in weight,—a figure the size of life being readily moved about by one person. It was an old process revived by the late Mr Owen Jones, and well carried out for him by M. Desachy, in the elaborate ornamented ceiling at St James's Hall, Piccadilly. Carved work. Decora work.

Gilding is applied to castings as well as to carvings; but the former being, almost as a matter of course, less sharp and spirited in their flexures and details, as well as less firm in substance than the latter, castings can less bear to be further subdued by the application of foreign matters to their surfaces than carvings may. Gilding is the application of gold leaf to surfaces, which require, however, to be previously prepared for its reception. The work is first primed with a solution of boiled linseed oil and carbonate of lead, and then covered with a fine glutinous composition called gold size, on which, when it is nearly dry, the gold leaf is laid in narrow slips with a fine brush, and pressed down with a piece of cotton wool held in the fingers. As the slips must be made to overlap each other slightly, to insure the complete covering of the whole surface, the loose Gilding

edges will remain unattached; these are readily struck off with a large sable or camel-hair brush, fitted for the purpose; and the joints, if the work be dexterously executed, will be invisible. This is called oil gilding, and it is by far the best fitted for the enrichment of surfaces in architecture, because it is durable, and is easily cleaned, and does not destroy or derange the forms under it so much as burnished gilding does. The latter requires the work to be covered with various laminæ of gluten, plaster, and bole, which last is mixed with gold size, to secure the adhesion of the leaf.

Glazing.

The business of the glazier, the manufacture of whose material has of late years improved and progressed in a very remarkable degree, may be confined to the mere fitting and setting of glass; even the cutting of the plates up into squares being generally an independent art, requiring a degree of tact and judgment not necessarily possessed by the building artificer.

Tools. The glazier is supplied with a diamond or other cutting tool, laths or straight-edges of various lengths, a square, a glazing-knive, a hacking knife, a hammer, a duster, a sash-tool, a two-foot rule, and a machine called a glazier's horse, which he fixes outside a window sill, and stands on to reach the upper panes for glazing or cleaning purposes, without removing the sash, and so injuring the beads and paint.

Materials. His materials are simply glass, putty, and priming or paint. The glass is supplied by the glass-cutter, of the qualities and sizes required for the particular work to be executed. The putty is made by the glazier himself, or by a labourer, of fine clean powdered chalk or whitening, well mixed and combined with linseed oil, and kneaded to the consistence of dough. No more putty should be made at once than is likely to be worked up in the course of a few days, as, the oil drying out, it becomes hard and partially set, and is therefore less available for its purposes. Priming is a thin solution of white (with a little red) lead, mixed in linseed oil. For ordinary glass, the sashes are sent to the glazier from the joiner, after having been fitted into their places, and only require to be glazed before they are permanently set or hung.

Glazing operations. Supposing that no preliminary process is required, such as stopping (the result of bad joiners' work) and knotting (and knotty stuff should not be admitted in sashes), the sashes require to be primed. The priming is laid on every part of the sash except the outer edges of the styles and of the bottom and top rails, with the sash tool or painting brush, that is, if the sashes are intended to be painted; for if not, the rebates only must be primed. The object of this is to prepare the material of which the sash is composed for the reception of the putty, which would not otherwise attach itself so firmly as it does after this preparation. The priming being sufficiently dry, the workman cuts the panes of glass down into their places, making every one fall readily into the rebates without binding in any part; indeed the glass should fit so nicely as not to touch the wood with its edges anywhere, and yet hardly allow a fine point to pass between it and the sash-bar or rebate, the object being to encase it completely in putty, and yet that the putty should not be in greater quantity than is absolutely necessary. The glass being fitted or cut down, the workman takes the glazing-knife in his right hand, and a lump of putty in the palm of his left, the sash being laid on its face, that is, with the rebates upward, before him; with the knife he lays a complete bedding of putty on the returning narrow stops of the rebates, all round to every pane. This being done, the panes of glass are put on it as they have been fitted, and every one is carefully rubbed down with the fingers, forcing the putty out below and round the edges of the glass, until they are nearly brought into contact with the wood or other material of the sash. The rebates are then filled in with putty behind, the mass forming exactly a right-angled triangle, its base being the extent of the stop of the rebate, and its perpendicular the depth from the glass to the outer edge of the rebate; and the third side or hypothenuse is neatly smoothed off. The sash being then turned on its edge and held upright by the left hand, the protruded putty of the bedding, or back putty as it is called, is struck off with the knife, and the section of it neatly drawn. The sashes are now deposited on their faces to allow the putty to set, and then they may be hung and painted.

To very large squares, and to plate glass, needle points, or small nails called sprigs, are used to retain the material securely in its place while the putty is soft and yielding. These have to be carefully inserted, for if they fix the glass it is apt to fly at any sudden vibration. Large squares and plate glass are usually inserted after the sashes are hung, to prevent risks of breakage. Where the bar and frame can be made to allow of it, large squares are secured in their place by wood beads screwed to the rebate in lieu of putty. In this case the edge of the glass is first covered with a piece of flannel, or thin india-rubber, to fill up crevices, and so prevent admission of dust, and stop any current of air.

Lead-work, as it is termed, is the glazing of frames rather than of sashes with small squares or quarries of glass, which are held together by reticulations of lead; and these are secured to stout metal bars, which are fixed to the window frames. Leaden reticulating bars are grooved on their edges to receive the quarries, and are tied by means of leaden ribands or wires to the saddle bars, which, in their turn, are affixed to the stouter bars before mentioned, if the bay or frame be so large as to require both. This is now extensively carried on in the painted glass window shops, where the glass is cut to patterns, and shows outlines of figures, costumes, &c. "Stained glass" is obtained by mixing colours in the pot while in the furnace, hence the term "pot metal" for it. A kind of coloured glass has only a skin of colour on one side of the white material, and hence is termed "flashed glass." Lead-w

Besides all the varieties of clear glass, the glazier has Va.. now at his command the many qualities of obscured glass, glass. beyond the ground and painted glass of former days; the lace-pattern glass, executed by laying a pattern on the material which has been covered with a varnish, placing it in a box filled with a fine powder, which when shaken adheres to the varnished portions, and then putting it in a kiln where it becomes fixed; the patent rough plate for conservatories, workshops, &c., and its fluted varieties; the rough cast plate for workshops and store-houses; the stained ornamented quarry for church windows, &c. Lastly, there is the engraving on glass by aid of the sand blast,—a new and easily managed method, consisting in a jet of air blown violently through a tube, carrying with it particles of fine sand. The action is very rapid, and it reduces the surface in a few minutes to the condition of ground glass. A piece of lace, however, is sufficient to arrest the action of the sand. Reece's patent embossed and coloured glass is useful for screens and for windows which are not meant to be looked through.

Coming within the scope of the glazier's business is the novel pavement light, consisting of a frame of iron cast with small many-sided apertures, into which are placed a series of dome-shaped or prism-shaped blocks of glass, reflecting the light falling upon them. They distribute the light to a greater extent than a piece of rough plate-glass, and like Chappuis's and other reflectors require to be kept clean. Moore's window ventilator allows of the

admission of air through its louvres, which are worked by a wire or cord as necessary. Hartley's patent perforated glass attempts to gain the same end by small slits formed in the pane.

For publications relating to the glazier's chief material, see the article GLASS. For patterns of lead-work, see Shaw's reprint of W. Gidde, *Booke of Sundry Draughtes*, 8vo, 1615.

SMITH-WORK AND GASFITTING.

The smith is the worker in wrought metals of all kinds required chiefly by the carpenter and joiner, who fixes them in the building. Smithery is the art of uniting several lumps of iron into one lump or more, and forging them to any desired shape. The earlier parts are done at the forge and on the anvil with the hammer, and hence is produced "wrought work," whether for useful or for ornamental purposes. Machinery has been brought extensively to the smith's assistance, for rolling, drilling, planing, &c. The ornamental portion of his work is wrought iron shaped by hand into devices and patterns according to the various styles of architecture, as in gates, railings, standards, hinge bands, locks, handles, knockers, lanterns, candlesticks, and other lighting contrivances, which are also executed in brass-work and in cast-iron.

's The founder's work is all cast metal, such as for ornamental gates and railings, rain-water pipes, cistern heads, and other portions, guttering, stable-fittings, coal-plates, &c. These commonly require to be fitted and fixed by the smith. The founder supplies all fire-grates, stoves, and other apparatus for warming and also for ventilation.

g. The gasfitter is a smith who supplies and fixes cast-iron pipes for diameters above two inches, and wrought iron for those of smaller bore, where gas is required to be used. A three-quarter inch pipe is considered by some as the least size to be used even for supplying rooms on an upper story; tin or composition metal pipes are fixed for sizes under half an inch, and also flexible tubes. It is recommended that no pipes should be embedded in the plastering, as is usually the case. In Paris the gas pipes must be seen for their whole length, and where passing through a floor or partition they must be let through a larger pipe having both ends open. Lights should not be fixed within 36 inches beneath wood-work. The solar or sun light is one of the modern additions for lighting large halls, as well as for dwelling-rooms; the globe lights, and some others of the same kind, all assist also in ventilating the apartments by tubes carrying off the products of combustion, which tubes are ordinarily fixed in the thickness of the floor; and as the air therein is raised to a very high temperature, great precautions are required to prevent danger by fire to the timbers, and also where the tubes pass through the roof. The effect of continued hot air on wood is little understood by the public generally. The star light, an invention of the late Mr Owen Jones, consists of a number of jets placed either horizontally or slightly inclining upwards at the jets; this is productive of a pleasing and brilliant light. There are many varieties of gas burners, such as the one called a fish tail, from which the form of the flame is the worst as regards economical results; the bat's-wing is better, and the argand is the best. The latter is a metal ring, pierced with numerous small holes, which divide the flame and allow of the proper combustion of the gas. Besides the common metal burners, there are some made with a soapstone or other cap, to prevent corrosion; and one of the better class is Bronner's patent burner, into which the gas is admitted through a very small opening adapted for supplying only a certain quantity of gas per hour. The usual burners have a large opening up to where the gas is consumed, and hence a waste of it.

HOUSE-PAINTING.

The real object of painting is to protect wood, metals, and stuccoes from the action of the atmosphere, by covering them with a material which is capable of resisting it. A continued succession of moisture and dryness, and of heat and frost, soon effects the decomposition of woods, causes oxidation in most of the metals used for economic purposes, and destroys the generality of stuccoes if their surfaces be exposed nakedly to it. A solution of ceruse or white lead in linseed oil spread over them prevents these injuries in a great measure, and for a considerable period of time; and as the application of such an unction can be repeated without much trouble or expense as often as occasion may require, it may be said to furnish a protection against the contingencies named. In addition to the utility of painting, it is also available as an ornament, by bringing disagreeably or diversely coloured surfaces to a pleasing and uniform tint, or by diversifying a disagreeable monotony of tint, to suit the taste and fancy; and this is done in a great measure by the addition of various pigments to the solution before mentioned.

The painter works with brushes of various sizes, made Tool of hog's bristles, or of hair with a mixture of bristles, and pencils made of badger's hair; these, with the addition of pots to hold his colours, a grinding-stone and grinder or muller for grinding or triturating them, a pallet and a pallet knife, dusting brushes and a scraping knife for cleaning iron-work before repainting, are almost his only implements. In painting the outside of windows he sometimes uses the glazier's horse. His materials are comparatively few also; but for some purposes these require a great variety of ingredients, the preparation and combination of which, however, now devolves principally on the manufacturer or colourman, and not on the painter himself. The colours are ground with a muller, which Colo is worked on the stone until they become a very fine powder; with some, the more they are ground the better is the colour. The powder is moistened with a little water or oil, as necessary, from time to time. They should all be ground separately; it is not good to produce a tint by mixture until they are well prepared. Only the quantities necessary for the work undertaken should be got ready. Common colours are those which are produced by the addition to white lead (or zinc white) and oil of lamp-black, red lead, or any of the common ochres; blues, greens, rich reds, pinks, and yellows, &c., being more costly, are taken as such. Unflatted white is a common colour; flatted it classes with the rich colours. If the same surface be painted of two different tints, it is said to be in party colours. The substance generally constituting nine-tenths of the body of paint is carbonate of lead, commonly called white lead, the quality of which is therefore of the greatest importance.

to the durability of the work. It is said to improve by being kept for several years before use. Three qualities are manufactured, and there are six or more chief modes of adulteration recorded, which accounts in some measure for the great difference in painters' prices, and the relative values of their work when done. The other metallic white paint occasionally used, especially in water colour painting, is zinc white. It is well known for its intense whiteness, its resistance to sulphurous and other deteriorating causes, and its harmless qualities to the workman and the inmates of the house under decoration. Zinc white possesses less body than white lead, and great care is requisite that the colour when ground in oil is of sufficient consistence to be laid on a flat surface without showing through; any oil in excess will form a slight glutinous coating on the surface, retaining every particle of dust brought in contact with it, until it has evaporated. In general this white does not dry so quickly as the other colour, but this defect is remedied by the application of proper drying oils. It is asserted that in consequence of the great durability of the colour, the paint may be washed for a succession of three, four, and even five years; and that after each successive washing the surface will be found as clear and bright as when fresh painted.

ng work. In painting or laying on the colour, the brush must be constantly at right angles to the face of the work, only the ends of the hairs, in fact, touching it, for in this manner the paint is at the same time forced into the pores of the wood and distributed equally over the surface. If the brush be held obliquely to the work, it will leave the paint in thick masses wherever it is first applied after being dipped for a fresh supply into the pot, and the surface will be daubed, but not painted. Painting, when properly executed, will not present a shining, smooth, and glossy appearance, as if it formed a film or skin, but will show a fine and regular grain, as if the surface were natural, or had received a mere stain without destroying the original texture. Imitative grainings, however, and the varnishes which are intended to protect them, and make them bear out, necessarily produce a new and artificial texture; and for this reason some consider them to a greater or less extent disagreeable, however well the imitations may be effected. Carved mouldings and other enrichments have to be picked out with a pencil or small brush, that the quirks, &c., be not choked up.

As it must be presumed that all the wood submitted to the operations of a painter, which has passed through the hands of the joiner, is already well seasoned and properly dry, it is only necessary to say generally, that the work should be free from moisture of any and every kind before paint is applied to it, or it will at the least prove useless, and probably injurious rather than beneficial. This remark applies alike to wood and to plastered work, both internal and external; that is, whether they be subjected to the more violent changes of the weather or not. Dampness or moisture in woods, stopped in or covered up with paint, will, under ordinary circumstances, tend to their destruction; and in stuccoes it will spoil the paint, and most probably injure the plastering itself also. The first thing the workman has to attend to in painting new wood-work is to prepare its surface for the reception of paint, by counteracting the effect of anything that may tend to prevent it from becoming identified with the ma[illegible]. Thus, in painting pine-woods, the resin in the knots which appear on the surface must be neutralized, or a blemish will appear in the finished work over every resinous part. In best work the knots should be cut out to a sligth depth at the bench, and the holes filled up with a stiff putty made of white lead, japan, and turpentine. The next best way is to cover them with gold or silver leaf. The usual method is to cover them with a size knotting, which is a preparation of red lead, white lead, and whitening made into a thin paste with size. The common coating of red ochre is worth nothing.

Coats of paint. The next process is that of priming, which consists in giving a coat of white lead with red lead and a little drier in linseed oil. This is the first coat, upon which the look of the finished work much depends. Inequalities or unevennesses of surface must be reduced with sand-paper or pumice-stone, or made up with putty. The necessary process for killing knots will generally leave a film, which must be rubbed down; and the heads of nails and brads having been punched in, will present indentations, which should be stopped, as well as any cracks or other imperfections, with putty. A second coat is then given, consisting of white lead and linseed oil. It should have a good body, and be laid even. This coat, when thoroughly dry, is in best work rubbed down with fine sand paper and carefully examined to ascertain if any further stopping be required; and then the third coat or ground colour is applied, of a somewhat darker tint than wanted when finished, having sufficient oil for easy working, but not too fluid,—about two-thirds oil and one-third turpentine are used. The flatting coat follows, the object of which is to do away with the gloss or glaze of the oil, by obtaining a flat appearance. White lead is mixed with turpentine, with sometimes a little copal varnish; the colouring matter is added, but always lighter than the ground colour, or it would when finished appear in a series of shades and stripes. Flatting must be executed quickly, on account of the evaporation of the turpentine, and the brush is generally, if not always, carried up the wall and not across it. Some painters use a large quantity of turpentine in the several coats for quick work, as it dries more rapidly; but for good and lasting work no turpentine should be used. Flatted work is generally done only to best apartments, chief staircases, entrance halls, &c., and omitted in the upper rooms, in bedrooms, and in basements. All new wood-work should be painted a sufficient number of coats to "bear out" as it is called; this is a precaution against each coat being so much diluted with turpentine or other fluid as not to cover sufficiently, which is seen by a deadness in one part and a glaze in another. The priming coat and three others should be sufficient. Sometimes plaster and new wood are first done over with clearcole, which is white lead ground up in water and size added. This prevents absorption of the oil, but the paint added subsequently is apt to blister or to crack off; it therefore should not be allowed.

Painting or plaster. Plaster and stucco to be painted requires some care in the workmanship of it, as noticed under "Plaster-work," *supra*, to prevent bubbles, and must be quite dry. Some persons recommend a priming or a second coat of strong double size; the next coat then consists of white lead in oil as stiff as possible, and then another coat of size, and so on; but such work should be repudiated. A good first coat of priming, as much as the stucco will absorb, is essential.

Outside painting. All new outside work should be primed with red lead or litharge, mixed in linseed oil; the second coat is of the same mixture if four-coat work is to be done, and in this coat all defects are to be made good; the third and fourth coats, as may be determined upon, are generally of the tint required.

Old work. In painting old work, where two coats are generally considered sufficient, the surface must be well washed to get rid of all dirt and grease, and then rubbed down with pumice-stone to remove all inequalities. The work then receives one coat, after which any holes are stopped by the painter with putty; the second and perhaps a third

coat, or a flatting coat, are then applied. Sometimes each of the earlier coats is rubbed down.

Old ceilings and soffits of stairs are either washed to clean off the dirt and grease, stopped (which is cutting out the cracks and stopping them with new plaster), and whitened by a coat of whitening or Spanish white mixed with size; or after the two first operations they are finished in distemper, which is white lead and size; it presents a better appearance. Colouring is also done to plastered walls, the white being mixed in half linseed oil and half turpentine, and some earth added to make the tint required. Limewhiting is done by the bricklayer's labourer. Stucco or plaster-work, which is intended to be painted, but which is not sufficiently dry to receive the oil, may have a coating of water colours, or distemper colour, as it is called, in order to give a more finished appearance to that part of the building. The colour selected should be ground very fine, and incorporated with the whiting and parchment, or other strong size. Two coats will be required to make it bear out uniformly. When the stucco is sufficiently dry, and it is desired to be painted, the whole of the above colouring has to be washed off, and the painting proceeded with as described for new work.

Metal-work, not being absorbent, only requires when new to have a priming, and one, two, or three coats of oil paints, as may be considered necessary. It should have a coat as soon after it leaves the founder or smith as possible, to prevent early stages of oxidation. Old work should be cleaned, scraped, and filed if necessary, to remove rust, broken paint, and dirt.

Graining is understood among painters to be the imitating of the several different species of ornamental woods, as satin-wood, rose-wood, king-wood, air-wood, mahogany, wainscot or oak, and others. After the necessary coats of paint have been put on to the wood, a ground is then laid of Naples yellow and ceruse, diluted with turpentine if for satin-wood, which is left to dry. The painter then prepares small quantities of the same yellow and ochre with a little brown, and boiled oil and turpentine, and having mixed this, spreads it over some small part of his work. The flat hog's hair brushes being dipped in the liquid and drawn down the newly laid colour, the shades and grainings are produced. To obtain the mottled appearance, the camel's hair pencils are applied, and when completed the work is left to dry, and afterwards covered by a coat or two of good copal varnish. Imitation wainscot requires the use of combs of various degrees of fineness to obtain the grain (whence the process is called *combing* by some persons), and the flower is got by wiping off the colour with a piece of rag. When dry it is over-grained to obtain a more complete representation of the natural wood, and then varnished. If the work be done in water colour and not in oil, beer grounds to act as a drier are mixed with the colour, this sets it ready for varnishing. A "patent graining-machine," a sort of roller with a pattern upon it, has lately been introduced. The writer of this article suggested some years ago that deal well sized to prevent absorption might be at once grained either wainscot or pollard oak, without the preliminary operation, delay, and smell of painting. When dry it is to be varnished as usual. The effect is somewhat better than that obtained by the usual method of graining.

Marbling is the imitation of real marbles, granites, &c., some of which are represented by splashing on the carefully prepared ground, which should have been painted and often rubbed and polished to obtain an even surface; others have to be painted in colours, and then well varnished. The most expert at this sort of imitation do their work so as to prevent its easy detection except by the touch.

Ornamental painting embraces the execution of friezes and the decorative parts of architecture on walls and ceilings in chiaroscuro (or light and shade) or monochrome colouring. The ground is well prepared, and of the tint of the proposed work; the ornament and figures are drawn upon it, and are then painted and shaded to give them their due effect. This kind of work is sometimes painted on cloth and then fastened up. When the ornamental work is of a similar pattern throughout, as mouldings, fretwork, a running ornament, &c., it is effected by stencilling. This method consists in drawing a certain length of the pattern on paper, which is pricked through with a large sized needle, then laid on the wall to be ornamented, and struck with a small linen bag containing powdered chalk; the chalk enters the apertures, and fixes itself against the paint. The painter then draws it, or fills in the pattern with colours. Another method is to cut out the pattern where possible, and the paper, being stiffened with size, is laid on the surface, and a brush filled with the colour passed over it; the paper is carefully removed and laid on a fresh place, and so on. The pattern may then be touched up when dry with another tint, or with gold, or another pattern with minuter detail laid on it, and the operation repeated. A wall surface may be covered with such an ornamentation, of which paper hangings are a cheap substitute.

Many of these methods of decoration having been styled shams, the promoters of real woods advocated the disuse of paints, &c. This has led to the increased use of deals and pines for inside doors, wainscots, linings, shutters, and the like, which, if not left as completed by the tradesmen, are sized and varnished or polished. But in such a case a good selection of the wood is necessary, and it has to be picked. Another method is to stain the timber, as of roofs, galleries, and the like, or the joiners' work, so that it represents various tints of oak, and this is protected by a coat or two of varnish. These systems are open to the objection that the varnish, especially in towns, darkens rapidly, and every coat of it adds to the defect, so that in a few years paint is required to give the work the clean and lively appearance the wood originally possessed. Real wainscot, mahogany, and other woods are usually polished; the first is sometimes varnished after being properly prepared to prevent the rise of the grain which occurs when it is touched by a liquid.

Varnishing having been frequently referred to, we must notice that there are many varieties useful for various purposes. Like white lead, oil, and turpentine, they are subject to much adulteration, whereby the work is deprived of its proper consistency, and the painter and his employer dissatisfied with the result. There are drying varnishes made with spirit of wine; these are applied to some furniture, mouldings, &c. Varnishes made with essential oils, especially those made with oil of turpentine or ether and pure copal, are very solid, and better than those made with fat drying oils, which, from their colour being dark, are used only with grounds of a dark colour. Varnish can sometimes be tinted to correct defects of colour in graining, &c. For wood-work copal varnish in oil should alone be used.

It is not within our province to enter upon the higher class of painting on walls, which comes under the trade of the decorator, including that of the gilder and the artistic draughtsman and colourist, nor upon the higher class of paper-hangings. Decorations must necessarily depend upon the taste and skill required or employed in producing them. Paper-hangings are paid for by the piece or yard, a piece being made in England twelve yards long and twenty inches wide, and the hanging is charged at so much the piece. A dozen of borders is twelve yards long; they are charged by the yard for the material, and by the dozen for hanging. Sizing and otherwise preparing the

walls may be requisite before hanging the papers; and washing old papers from off the walls should always be insisted upon by the owner of a house, as accumulations of paste, colours, and size are apt to breed vermin, and, as some think, to give rise to fevers. French paper-hangings are only eighteen inches wide and nine yards long. Wood-linings, old panelled wainscoting, and other irregular surfaces, require to be canvased and papered before the decorative paper is hung, otherwise it is liable to crack with the shrinking of the wood.

The principal publications on house painting are as follows:—Tingry, *Painter's and Varnisher's Guide*, 8vo, 1832, 3d edit.; Higgins, *Painter's and Decorator's Companion*, 4to, 1841; Arrowsmith, *House Decorator's and Painter's Guide*, 4to, 1840; Field, *Rudiments of the Painter's Art*, 12mo, 1850, and his *Chromatography*, 4to, 1841; Smith, *The Art of House Painting*, 12mo, 1687, improved by W. Butcher, 8vo, 1821; Whittock, *Decorative Painter's Guide*, 4to, 1841; Moxon, *Grainer's Guide*, 1842; Barber, *Painter's Assistant*, 12mo, 1852; *Wood and Marble Imitator's Manual*, 8vo, Edinb. There are two or three French journals which give examples of imitations of woods and marbles, and illustrations of decorations for apartments. (W. P.)

INDEX OF PRINCIPAL SUBJECTS.

Legal definition. BUILDING SOCIETIES, or societies "for the purpose of raising, by the subscriptions of the members, a stock or fund for making advances to members out of the funds of the society upon freehold, copyhold, or leasehold estate by way of mortgage," may be "either terminating or permanent" (37 and 38 Vict. c. 42, § 13).

A "terminating" society is one "which by its rules is to terminate at a fixed date, or when a result specified in its rules is attained;" a "permanent" society is one "which has not by its rules any such fixed date or specified result, at which it shall terminate" (§ 5).

Popular definition. A more popular description of these societies would be,—Societies by means of which every man may become "his own landlord," their main purpose being to collect together the small periodical subscriptions of a number of members, until each in his turn has been able to receive a sum sufficient to aid him materially in buying his dwelling-house.

Origin. The origin and early history of these societies is not very clearly traceable. A mention of "building clubs" in Birmingham occurs in 1795; one is known to have been established by deed in the year 1809 at Greenwich; another is said to have been founded in 1825, under the auspices of the earl of Selkirk at Kirkcudbright in Scotland, and we learn (Scratchley *On Building Societies*, p. 5) that similar societies in that kingdom adopted the title of "menages."

Acts of 1834 and 1836. When the Friendly Societies Act of 1834 gave effect to the wise and liberal policy of extending its benefits to societies for frugal investment, and generally to all associations having a similar legal object, several building societies were certified under it,—so many, indeed, that in 1836 a short Act was passed (6 and 7 Will. IV. cap. 32), confirming to them the privileges granted by the Friendly Societies Act, and according to them the additional privileges (very valuable at that time) of exemption from the usury laws, simplicity in forms of conveyance, power to reconvey by a mere endorsement under the hands of the trustees for the time being, and exemption from stamp duty. This Act remained unaltered till 1874.

The early societies were all "terminating,"—consisting of a limited number of members, and coming to an end as soon as every member had received the amount agreed upon as the value of his shares. Terminating societies.

Take, as a simple typical example of the working of such a society, one the shares of which are £120 each, realizable by subscriptions of 10s. a month during 14 years. Fourteen years happens to be nearly the time in which, at 5 per cent. compound interest, a sum of money becomes doubled. Hence the present value, at the commencement of the society, of the £120 to be realized at its conclusion, or (what is the same thing) of the subscriptions of 10s. a month by which that £120 is to be raised, is £60. If such a society had issued 120 shares, the aggregate subscriptions for the first month of its existence would amount to exactly the sum required to pay one member the present value of one share. One member would accordingly receive a sum down of £60, and in order to protect the other members from loss, would execute a mortgage of his dwelling-house for ensuring the payment of the future subscription of 10s. per month until every member had in like manner obtained an advance upon his shares, or accumulated the £120 per share.

As £60 is not of itself enough to buy a house, even of the most modest kind, every member desirous of using the society for its original purpose of obtaining a dwelling-house by its means would require to take more than one share. In this respect the Act of 1836 presented a curious inconsistency; it limited the amount of each share to £150, and the amount of the monthly contributions on each share to £1, but did not limit the number of shares a member might hold. If its purpose in this respect was to confine the operation of these societies to the industrial classes, it was defective. The only rational explanation of the provision is that it was an anticipation of the modern system of limited liability.

The earlier formed societies (in London at least) did not usually adopt the title "Building Society;" or they added to it some further descriptive title, as "Accumulating Fund," "Savings' Fund," or "Investment Association." Several are described as "Societies for obtaining freehold property." Names of societies.

or simply as "Mutual Associations," or "Societies of Equality." The building societies in Scotland are mostly called "Property Investment Companies," or by some similar name. Although the term "Benefit Building Society" occurs in the title to the Act of 1836, it was not till 1849 that it became in England the sole distinctive name of these societies; and it cannot be said to be a happy description of them, for as ordinarily constituted they undertake no building operations whatever, and merely advance money to their members to enable them to build or to buy dwelling-houses or land.

The name "Building Society," too, leaves wholly out of sight the important functions these societies fulfil as means of investment of small savings. The Act of 1836 defined them as societies to enable every member to receive the amount or value of a share or shares to erect or purchase a dwelling-house, &c., but a member who did not desire to erect or purchase a dwelling-house might still receive out of the funds of the society the amount or value of his shares, improved by the payments of interest made by those to whom shares had been advanced.

ιanent ties. About 1846 an important modification of the system of these societies was introduced, by the invention of the "permanent" plan, which was adopted by a great number of the societies established after that date. It was seen that these societies really consist of two classes of members; that those who do not care to have, or have not yet received, an advance upon mortgage security are mere investors; and that it matters little when they commence investing, or to what amount, while those to whom advances have been made are really debtors to the society, and arrangements for enabling them to pay off their debt in various terms of years, according to their convenience, would be of advantage both to themselves and the society. By permitting members to enter at any time without back-payment, and by granting advances for any term of years agreed upon, a continuous inflow of funds, and a continuous means of profitable investment of them, would be secured. The interest of each member in the society would terminate when his share was realized, or his advance paid off, but the society would continue with the accruing subscriptions of other members employed in making other advances.

istics. Under this system Building Societies have largely increased and developed. In the county of Middlesex alone, 1600 societies were certified between 1836 and 1874; in that of Lancaster, 1300; and the total number of societies established in England and Wales cannot be less than between 5000 and 6000.

Deducting the terminating societies which have reached their termination, and the permanent societies which have failed or been dissolved, it is estimated that more than 2000 societies are still in existence. The operations of some of these societies are very extensive. The Queen's Building Society at Manchester has an income of £734,578, and assets amounting to £910,224; a society at Halifax has an income of £261,654, and assets £430,683; one at Burnley £221,508 income, and £324,919 assets (*Report of Registrar*, 1875). There are also several large societies in Scotland.

The total funds and income of building societies cannot be accurately ascertained; but the Royal Commissioners who inquired into the subject in 1872, estimated the total assets of the societies in 1870 at 17 millions, and their annual income at 11 millions. The larger societies are in the North of England, where, indeed, all classes of provident associations, notably friendly societies and co-operative societies, are more fully developed than in the South. To this remark, however, there is one exception, viz., the Birkbeck Building Society, London, whose receipts for the year 1874 amounted to 4½ millions, but by far the larger portion of that enormous sum consisted of deposits paid to the society as a banker.

arr Bow- ett cieties. A variety of the terminating class of societies has met with some favour of late years, under the name of "Starr Bowkett" or "mutual" societies, of which about 200 have been established. They differ from the typical society above described, in the contribution of a member who has not received an advance being much smaller, while the amount of the advance is much larger, and it is made without any calculation of interest. Thus a society will issue say 500 shares, on which the contributions are to be 1s. 3d. per week, and, as soon as a sum of £300 has accumulated, will allot it by ballot to one of the shareholders, on condition that he is to repay it without interest by instalments in 10 or 12½ years, and at the same time to keep up his share-contributions. The fortunate recipient of the appropriation is at liberty to sell it, and frequently does so at a profit; but (except from fines) no profit whatever is earned by those who do not succeed in getting an appropriation, and as the number of members successful in the ballot must necessarily be small in the earlier years of the society, the others frequently become discontented and retire. These societies cannot, of course, borrow money, for as they receive no interest they cannot pay any. The plan has recently been modified by granting the appropriations alternately by ballot and sale, so that by the premiums paid on the sales (which are the same in effect as payments of interest on the amount actually advanced) profits may be earned for the investing members.

A further modification of the "mutual" plan is to make all the appropriations by sale. The effect of this is to bring the mutual society back to the ordinary form; for it amounts to precisely the same thing for a man to pay 10s. a month on a loan of £60 for 14 years, as for him to borrow a nominal sum of £84 for the same period, repayable in the same manner, but to allow £24 off the loan as a "bidding" at the sale. The only difference between the two classes of societies is that the interest which the member pays who bids for his advance depends on the amount of competition at the bidding, and is not fixed by a rule of the society. Appro tions b sale or

In 1874 an Act was passed at the instance of the building societies conferring upon them several valuable privileges, and relieving them of some disabilities and doubts, which had grown up from the judicial expositions of the Act of 1836. Building societies are now incorporated bodies, and the members, and all who derive title through them, henceforth will not have to trace that title through a succession of trustees for a society. Again, a distinct declaration is given to the members of entire freedom from liability to pay anything beyond the arrears due from them at the time of winding up, or the amount actually secured by their mortgage deeds. Power to borrow money is also expressly given to the societies by the Act, but upon two conditions:—that the limitation of liability must be made known to the lender, by being printed on the acknowledgment for the loan, and that the borrowed money must not exceed two-thirds of the amount secured by mortgage from the members, or, in a terminating society, one year's income from subscriptions. Act of 1874.

Previous to the passing of the Act (or rather to the judicial decision in *Laing* v. *Read*, which the clause of the Act makes statutory) there had been, on the one hand, grave doubts on high legal authority whether a society could borrow money at all; while, on the other hand, many societies in order to raise funds carried on the business of deposit banks to an extent far exceeding the amounts used by them for their legitimate purpose of investment on mortgage. It is now enacted, that if a society borrow more than the statute authorizes, the directors accepting the loan shall be personally responsible for the excess.

The history of building societies thus briefly traced shows great progress in the past and equal promise for the future. The social and moral utility of societies established for the direct purpose of aiding a man to become proprietor of his dwelling-house is obvious, and the extent to which that purpose has been effected is very considerable.

It may be mentioned that building societies flourish in America (notably in Massachusetts, where they are called "Mutual Loan Fund Associations," and Pennsylvania), and in the British colonies, especially that of Victoria, Australia. (E. W. B.)

BUITENZORG, the capital of an assistant-residency in the island of Java, is situated in 6° 37′ S. lat. and 106° 52′ E. long., and is 66 miles S. of Batavia, with which it has been connected by rail since 1872. Lying 830 feet above the level of the sea, and possessing a salubrious climate, it is becoming a favourite place of residence for the Dutch of the greater city. Its principal buildings comprise the new church, which serves both for Protestant and Roman Catholic worship, a mosque, the regent's mansion, excellent barracks for the garrison, a prison, built in 1848, a bathing establishment, and the country palace of the governor-general. This splendid edifice occupies the site of the old castle, which was founded in 1744 by Baron van Imhof, enlarged by Daendels in 1809, restored by Van der Capellen in 1819, and destroyed by an earthquake in 1834. The botanical gardens, laid out in 1817 by Van der Capellen, are among the finest and most extensive in the world. In

the neighbourhood of Buitenzorg is Batton-Toulis-Cocabatou, a sacred wood held in high veneration by the natives.

BUJALANCE, a town of Spain, in the province of Cordova, and about 25 miles E. of that city. It contains a Moorish castle flanked with towers, two hospitals, a foundling asylum, and a seminary for the education of girls. Leather and woollen cloth are manufactured. Population 8946.

BUKOWINA, a duchy and crown-land of the Austrian empire, bounded on the N. and N.W. by Galicia, W. by Hungary and Transylvania, S. by Moldavia, and E. by Moldavia and Russia. It has an area of 4036 English square miles, and the population in 1869 amounted to 511,964, of whom 255,919 were males and 256,045 females. The country, especially in its southern parts, is largely occupied by offshoots of the Carpathian mountains. Its northern border is skirted by the Dniester, and a considerable section is drained by the Pruth, but by far the larger portion belongs to the system of the Danube, and is watered by the head streams of the Sereth, the Moldava, and the Bistritza. The climate is healthy but severe, especially in winter; and the soil, particularly in the north, is of great fertility. A large part of the surface,—according to official statistics in 1870, no less than 1,050,849 acres, or nearly one-half of the whole,—is occupied by woodland; and the very name of the country is derived from the abundance of beech-trees. Wheat, rye, oats, maize, barley, beans, potatoes, flax, and hemp are all more or less cultivated; and about 643,319 acres of arable land are under tillage. Gardens and meadows occupy 301,706 acres, vineyards 11, and pasture 290,531. In 1870 the number of horses in the duchy was 42,649, cattle 224,424, sheep 217,913, goats 18,786, and swine 133,385, while the bee stocks amounted to no fewer than 27,091. The mineral productions comprise copper, iron, lead, silver, coal, salt, sulphur, and alabaster, some of which, however, are only yielded in very moderate quantities. In 1870 the iron ore obtained amounted to 5808 tons, the copper to 945, and the salt 2590. The principal mineral springs are at Dorna-Watra, Jakobeny, and Lopuszna, but none of them as yet are much frequented. The country is divided into the eight districts of Czernowitz, Kimpolung, Kotzmann, Radautz, Sereth, Storozynec, Suczawa, and Wisznitz, the capital Czernowitz forming a separate and ninth division. There are seven towns in all, eight market-villages, and 456 hamlets, the most populous places being Czernowitz with 33,884 of a population, Radautz 9429, Suczawa 7450, Sereth 6486, Kuszusmare 6419, and Kimpolung 5561. Industrial activity is still comparatively slight, the most important establishments being the breweries, of which there were fifteen in 1870, and the distilleries, which numbered forty-nine. The population is of various origin,—about 180,000 being Roumanians, 200,000 Ruthenians, and the rest Germans, Poles, Jews, Hungarians, &c. The German language alone is used in twenty-one of the village schools, and Roumanian in forty-nine, while in many both are in use. In 1869 there were 376,946 adherents of the Greek church, 74,347 Catholics, 11,393 Protestants, and 47,772 Jews, the total population amounting to 511,964, while in 1857 it was only 456,920. The Bukowina diet consists by the law of 1861 of thirty members, including, besides the bishop, ten appointed by the landed proprietors, seven by the towns, and twelve by the rural communes. Five members are sent to the imperial diet. Originally a part of Transylvania, Bukowina, passed in 1482 to Moldavia, and in 1775 to Austria, who united it in 1786 as the Czernowitz circle with Galicia, but in 1849 raised it to its present independence

BULACAN, the chief town of a province of the same name in the Philippine island of Luzon, situated on an arm of the Pampanga delta, about 15 miles N. of Manila. With the exception of the churches and a few stone buildings, it was completely destroyed by fire in 1859, but has since been rebuilt. Population estimated at about 10,000.

BULANDSHAHR, a district of British India, in the Meerut division, under the jurisdiction of the Lieutenant Governor of the N.W. Provinces; lies between 28° 3′ and 28° 43′ N. lat., and 77° 28′ and 78° 32′ E. long. It is bounded on the N. by the district of Meerut; on the E. by the districts of Moradabad and Budaun; on the S. by the district of Alígarh; and on the W. by the districts of Gúrgáon and Delhi. The district stretches out in a level plain, with a gentle slope from north-west to south-east, and a gradual but very slight elevation about midway between the Ganges and Jumna. Principal rivers, the Ganges and Jumna,—the former navigable all the year round, the latter only during the rains; minor rivers, Hindan and East Kálí Nadí, not navigable. The Ganges canal intersects the district, and serves both for irrigation and navigation. Area of Bulandshahr district, 1910 square miles, of which 1368 are under cultivation; 346 cultivable, but not actually under cultivation; and the rest uncultivable waste. Population in 1872, 936,593 souls, residing in 182,694 houses, and inhabiting 1566 villages; persons per square mile, 490; per village, 598; per house, 5·1. Of the total population 760,602 or 81·2 per cent. were Hindus; 175,900 or 18·8 per cent. Mahometans; and 91 Christians and others.

Cotton, indigo, sugar, wheat, tobacco, barley, millet, and various kinds of pulse, form the principal agricultural products. The chief traffic routes are—(1), Road from Meerut to Alígarh; (2), from Delhi to Bareilly; and (3), between Delhi and Anúpshahr. The East Indian Railway passes through the district. Total revenue in 1870–71, £176,422, of which £155,675, or 88 per cent., was from land. The regular constabulary police consisted of 523 men in 1870–71, besides the rural or village watch. Bulandshahr district contained 302 schools in 1872–73, attended by 6959 pupils. The following twelve towns in the district have upwards of 5000 inhabitants:—1. Baran or Bulandshahr, the administrative headquarters, situated on the right bank of the Kálí Nadí, on the route from Bareilly to Delhi, in 28° 24′ N. lat. and 77° 56′ E. long.; area, 111 acres; population, 14,804; municipal income in 1872, £1075; expenditure, £1139, 2s.; rate of municipal taxation, 1s. 5⅝d. per head. 2. Dibai—area, 106 acres; population, 7782; municipal income, £346, 16s. 9d.; expenditure, £298, 7s. 4d.; rate of taxation, 10⅝d. per head. 3. Anúpshahr—area, 123 acres; population, 9336; municipal income, £598, 14s.; expenditure, £532, 14s.; rate of taxation, 1s. 3⅝d. per head. 4. Jahángírábad—114 acres; population, 9408; municipal income, £571, 3s. 5d.; expenditure, £456, 12s. 9d.; rate of taxation, 1s 2⅝d. 5. Shikárpur—area, 115 acres; population, 11,150; municipal income, £435, 19s. 6d.; expenditure, £408, 11s. 9d.; rate of taxation, 9⅝d. per head. 6. Dankaur—area, 251 acres; population, 5423; municipal income, £189, 2s. 4d.; expenditure, £163, 9s. 1d.; rate of taxation, 8⅝d. per head. 7. Jhajhar—area, 50 acres; population, 5632; municipal income, £241, 15s. 5d.; expenditure, £199, 2s. 9d.; rate of taxation, 10⅝d. per head. 8. Jewar—area, 78 acres; population, 7399; municipal income, £282, 14s. 4d.; expenditure, £233, 17s. 1d.; rate of taxation, 9½d. per head. 9. Siyána—area, 65 acres; population, 6268; municipal income, £294, 14s. 5d.; expenditure, £251, 9s. 4d.; rate of taxation, 11¼d. 10. Gulaothí—area, 44 acres; population, 5608; municipal income, £239, 0s. 8d.; expenditure, £223, 2s. 7d.; rate of taxation, 10¼d. per head. 11. Khúrja—area, 206 acres; population, 26,858; muncipal income, £2301, 14s.; expenditure, £3028, 10s.; rate of taxation, 1s. 8⅝d. per head. 12. Sikandarabad—area, 199 acres; population, 18,349; municipal income, £988; expenditure, £539, 10s.; rate of taxation, 1s. 0¾d. per head. The climate of the district is liable to extremes, being very cold in the winter and excessively hot in the summer.

Towards the end of the last century, the district passed into the hands of Perron, a French common sailor, who had won his way up to the rank of a general in the Marhattá service. Its annexation formed one of the leading points in the Marquis Wellesley's policy, and it was ceded to us by the Scindia treaty of 1803. Bulandshahr enjoyed a bad conspicuousness in the mutiny of 1857, when the Gujar peasantry plundered the towns.

there are 4,000,000 in the Turkish empire, and Professor Szabo makes their number in Servia 100,000. As early as the 14th century emigration took place to the Banat, where the Bulgarians number upwards of 23,000; and in Transylvania there is a colony which retains its dialect. (See *Denkschriften d. Wien. Akad., Phil.-hist. Cl.*, 1856.) Much more important are the Bulgarian settlements in Bessarabia, which in 1862 numbered 70,000 inhabitants. These began to be formed as early as 1787, and received strong accessions from 1801 to 1812. The chief town which owed its existence to this transmigration is Bolgrad, on Lake Yalpuk, which passed with a portion of Bessarabia to Moldavia in 1851. About 1865 it had 9000 inhabitants.

BULGARIN, Thaddäus (1789–1859), a distinguished Russian writer, was born in Lithuania. His father was an officer under Kosciusko in the last disastrous Polish campaign. By some influence of friends Thaddäus was entered at the college for military cadets at St Petersburg, and afterwards received a commission in the Russian army, with which he served against Napoleon and in Finland. He then left the Russian army, joined the Poles under Napoleon, and took part in nearly all the great campaigns in Spain, Germany, and Russia. After the fall of the emperor he took up his residence in Warsaw, and devoted himself to literature, writing in his native Polish language. In 1819 he removed to St Petersburg, learned Russian, and became Russian in every way. He edited, alone or in conjunction with Gretch, the *Northern Archives*, the *Northern Bee*, and the *Russian Thalia*. In 1829 his first novel, *Ivan Vuizhagen*, gained great popularity. A continuation was afterwards published under the title *Peter Ivanovitch Vuizhagen*. His other works comprise two novels, *Demetrius* and *Mazeppa*, an *Account of Russia* (Russia in an historical, statistical, geographical, and literary point of view), and his *Reminiscences*. An English translation of his best novel, *Ivan Vuizhagen*, was published in 1831.

BULGARUS, the most celebrated of the famous "Four Doctors" of the law school of Bologna. He is sometimes erroneously called Bulgarinus, which was properly the name of a jurist of the 15th century. Bulgarus was a native of Bologna, and was regarded as the Chrysostom of the Gloss-writers, being frequently designated by the title of the "Golden Mouth" (*os aureum*). The time of his birth is not known. A popular tradition represents him to have been a pupil of Irnerius, but unfortunately nothing is known of Irnerius after 1118 A.D. Bulgarus, on the other hand, died in 1166 A.D., having attained a great age, and having become childish before his death. There is thus no inseparable difficulty in point of time in accepting this tradition as far as regards Bulgarus, although Savigny considers the general tradition to be inadmissible which represents all the Four Doctors to have been pupils of Irnerius. Martinus Gosia was the next most celebrated of the Four Doctors. He and Bulgarus were the chiefs of two opposite schools at Bologna, corresponding in many respects to the Proculians and Sabinians of Imperial Rome, Martinus being at the head of a school which accommodated the law to what his opponents styled the equity of "the purse" (*æquitas bursalis*), whilst Bulgarus adhered more closely to the letter of the law. The school of Bulgarus ultimately prevailed, and it numbered amongst its adherents Joannes Bassianus, Azo, and Accursius, each of whom in his turn exercised a commanding influence over the course of legal studies at Bologna. Bulgarus took the leading part amongst the Four Doctors at the diet of Roncaglia in 1158, and was one of the most trusted advisers of the Emperor Frederick I. His most celebrated work is his commentary *De Regulis Juris*, which was at one time printed amongst the writings of Placentinus, but has been properly reassigned to its true author by Cujacius, upon the internal evidence contained in the additions annexed to it, which are undoubtedly from the pen of Placentinus. Savigny considers this *Commentary*, which is the earliest extant work of its kind emanating from the school of the Gloss-writers, to be a model specimen of the excellence of the method introduced by Irnerius, and a striking example of the brilliant results which had been obtained in a short space of time by a constant and exclusive study of the sources of law.

BULL, Papal. See Bulls and Briefs.

BULL, George (1634–1710), bishop of St David's, was born at Wells, and educated at Tiverton school, Devonshire. He entered Exeter College, Oxford, but had to leave in consequence of his refusal to take the oath of allegiance to the Commonwealth. He was ordained privately by Bishop Skinner in 1655. The first benefice he enjoyed was that of St George's near Bristol, from which he rose successively to be rector of Suddington in Gloucestershire, prebendary of Gloucester, archdeacon of Llandaff, and in 1705 bishop of St David's. He died February 17, 1710. During the time of the Commonwealth he adhered steadily, though with great prudence, to the forms of the Church of England, and in the reign of James II. preached very strenuously against the errors of Romanism. His works are among the most solid contributions made to theological learning by the Church of England. They uniformly display great erudition and powerful thinking. The *Harmonia Apostolica*, published in 1670, is an attempt to show the fundamental agreement between the doctrines of Paul and James with regard to justification. The *Defensio Fidei Nicenæ*, his greatest work, published in 1685, tries to show that the doctrine of the Trinity was an article of faith in the Christian church before the Council of Nicæa. It still retains value as a thoroughgoing examination of all the pertinent passages in early church literature. The *Judicium Ecclesiæ Catholicæ* obtained for him the thanks of the French clergy. His last treatise, *Primitive and Apostolical Tradition*, was published shortly before his death. The best edition of his works is that in 7 vols., published at Oxford by the Clarendon Press, under the superintendence of the Rev. E. Burton. This edition contains the *Life* by Nelson. The *Harmonia, Defensio,* and *Judicium* are translated in the Library of Anglo-Catholic Theology.

BULL, John, a distinguished English composer and organist, was born in Somersetshire about 1563. In 1591 he was appointed organist in the Queen's chapel in succession to Blitheman, from whom he had received his musical education; in 1592 he received his degree of doctor of music at Cambridge University; and in 1596 he was made music professor at Gresham College, London. As he was unable to lecture in Latin according to the foundation-rules of that college, the executors of Sir Thomas Gresham made a dispensation in his favour by permitting him to lecture in English. He gave his first lecture on 6th October 1597. He afterwards visited France and Germany, and was everywhere received with the respect due to his talents. The story told by Anthony Wood of Dr Bull's feat at St Omer, which consisted in adding, within a few hours, forty parts to a composition already written in forty parts, is simply impossible. Honourable employments were offered to him by various Continental princes; but he declined them, and returned to England, where he was appointed organist to James I. in 1607, and in the same year resigned his Gresham professorship. In 1613 he again went to the Continent on account of his health; and, in the Netherlands, entered into the service of the archduke. In 1617 he was appointed organist to the cathedral of Nôtre Dame

at Antwerp, and he died in that city on the 12th March 1628. The usual statement that he died at an earlier date at Hamburg or Lübeck is incorrect. Little of his music has been published, and the opinions of critics differ much as to its merits. A claim made on his behalf to the composition of the music of the English national anthem has given rise to much discussion, but it seems now generally agreed that the claim is not well founded. Contemporary writers speak in the highest terms of Bull's skill as a performer on the organ and the virginals.

BULLA (literally a bubble) was the term used by the Romans for any boss or stud, such as those on doors, sword-belts, shields, &c. It was applied, however, more particularly to an ornament, generally of gold, worn suspended from the neck by children of noble birth until they assumed the *toga virilis*, when it was hung up and dedicated to the household gods. See COSTUME. In ecclesiastical and mediæval Latin, *bulla* denotes the metal seal of oval or circular form, bearing the name and generally the image of its owner, which was attached to official documents. The bulla of the empire was of gold, while the Papal bulla was of lead. See BULLS and BRIEFS.

BULLFINCH (*Pyrrhula vulgaris*), a species of conirostral bird belonging to the family *Fringillidæ*, of a bluish-grey and black colour above, and generally of a bright tile-red beneath, the female differing only in having its colours somewhat duller than the male. It is a shy bird, not associating with other species, and frequents well-wooded districts, being very rarely seen on moors or other waste lands. It builds a shallow nest composed of twigs lined with fibrous roots, on low trees or thick underwood, only a few feet from the ground, and lays four or five eggs of a bluish white colour speckled and streaked with purple. The young remain with their parents during autumn and winter, and pair in spring, not building their nests, however, till May. In spring and summer they feed on the buds of trees and bushes, choosing, it is said, such only as contain the incipient blossom, and thus doing immense injury to orchards and gardens. In autumn and winter they feed principally on wild fruits and on seeds. The note of the bullfinch, in the wild state, is soft and pleasant, but so low as scarcely to be audible; it possesses, however, great powers of imitation, and considerable memory, and can thus be taught to whistle a variety of tunes. Bullfinches are very abundant in the forests of Germany, and it is there that most of the piping bullfinches sold in this country are trained. They are taught continuously for nine months, and the lesson is repeated throughout the first moulting, as during that change the young birds are apt to forget all that they have previously acquired. The bullfinch is a native of the northern countries of Europe, occurring in Italy and other southern parts only as a winter visitor. White and black varieties are occasionally met with; the latter, it is said, on the authority of White of Selborne, may be produced by feeding the bullfinch exclusively on hemp-seed, when its plumage gradually changes to black. It breeds in confinement, and hybrids between it and the canary have been produced.

BULLINGER, HEINRICH (1504–1575), an eminent Reformer, was born at Bremgarten, near Zurich. He studied at Emmerich and Cologne, where he read some of Luther's works, and after his return home lectured at the abbey of Kappel. In 1527 he heard Zwingli at Zurich, and in the following year he accompanied him to the great conference at Berne. He was made pastor at Bremgarten in 1529, and married one Anna Adlischwegler, formerly a nun. In 1531 he had to fly to Zurich in consequence of the Catholic victory at Kappel, and was soon afterward appointed minister of the principal church. He was a powerful upholder of the Zwinglian doctrine of the Lord's Supper, and wrote an able defence against Luther. He had also numerous controversial writings against the Anabaptists. His printed works are very numerous, and many of them were translated into English. They form ten vols. folio. Bullinger died at Zurich in 1575.

BULLION is a term applied to the gold and silver of the mines brought to a standard of purity. The term is of commercial origin, and has reference to the precious metals as a medium of exchange. It followed from this office of gold and silver that they should approximate in all nations to a common degree of fineness; and though this is not uniform even in coins, yet the proportion of alloy in silver, and of carats alloy to carats fine in gold, has been reduced to infinitesimal differences in the bullion of commerce, and is a prime element of value even in gold and silver plate, jewellery, and other articles of manufacture. All the new gold and silver coinage of France, Germany, Spain, Italy, Belgium, and the United States—probably of a still wider circle of the principal coining countries in the world—contain nine-tenths of pure metal. The coinage of Russia is on the British standard of eleven-twelfths, as nearly as it can be expressed in simple fractions of pure gold and silver, the alloy in silver being a little more in all cases than the alloy in gold. Bullion, whether in the form of coins, or of bars and ingots stamped, is subject, as a general rule of the London market, not only to weight but to assay, and receives a corresponding value.

The recognition of gold and silver from the earliest times as a convenient means of purchase, their ultimate adoption as a prevailing standard of value, their coinage by all the richer states into pieces of money, in virtue of which their circulation and absorption have been immensely increased, and the extent to which they have become the necessary financial reserve of Governments, banks, trading companies, and merchants, have given to these metals a greatly more extended use and importance than they could have acquired in the ordinary process of arts and manufactures; though even in this latter sphere, as gold and silver become more abundant and communities richer, the purposes to which they are applied and the demand for them are susceptible of much expansion. Writers of high authority have attempted at various periods to estimate the production of gold and silver, and correlatively their use and consumpt in the monetary system and the arts; but there is scarcely any subject of statistical inquiry on which it is so difficult to arrive at more than conjectural results. Yet in view of the theoretical speculations that arose on the Californian and Australian gold discoveries, the produce of these new fields of supply may here be worthy of notice. The Californian mines were computed to have in three years yielded gold to the value of £35,000,000 sterling. The Australian mines, still more prolific, were estimated in three years from their opening to be equal to an annual produce of £20,000,000 sterling. Such results, sustained over a considerable period of years, presented a phenomenon similar to the more slowly developed effects of the discovery of the South American mines in the 16th century; and it must be admitted that California and Australia, after many reverses in their mining industry, remain the most gold-productive countries in the world. But their produce of bullion has of late years much fallen in amount.

The director of the United States' Mint, in his report for 1875, estimates the annual yield of gold and silver in California and other United States possessions at $100,000,000, or about £20,000,000. The total export of bullion and specie from Australia, after deducting the import (chiefly intercolonial), varied in the fifteen years 1858–1872 from 11¼ to 7½ millions sterling per annum the general tendency being towards the lower amounts in the later years (*Statistical Abstract for Colonial and*

other Possessions of United Kingdom, 1874). The annual average export in these fifteen years was £9,747,635, and must be held to measure amply the produce of the gold and silver mines of Australia. The annual production of bullion in the United States and Australia cannot, on these data, be estimated at more than 28 millions sterling. Humboldt found the annual produce of the gold and silver mines of America, Europe, and Northern Asia, at the beginning of the century, to be about £9,700,000. The yield of gold and silver from the same sources in 1850-57 was estimated by M'Culloch, in the *Commercial Dictionary*, to be £14,000,000. The old gold and silver mines can hardly have become more productive since the advent of the Californian and Australian diggings, so that it would appear the latter have increased the visible annual supply of gold and silver about threefold, or from £14,000,000 to £42,000,000. Japan, so far as can be judged from the exchanges, must now be added to the list of gold-producing countries. For several years in succession Japan has exported considerable and apparently increasing amounts of treasure, or gold and silver coins of its own mint. In 1874 this export amounted to $13,332,794, or nearly three millions sterling (Sir Henry Parkes's *Summary of Consular Reports*). During the first six months of 1875 the imports of bullion from Yokohama to London were £1,257,170 gold, £95,080 silver; and not improbably the next great access of the product of gold-mines may be from that part of the world. But notwithstanding this marked increase of gold and silver since 1850, when one considers the increase of population, the still greater increase of trade and industry, and the vast extension of financial and commercial affairs in the same period, it may be held doubtful whether gold and silver have lost any of their old proportion to the need for them and to the work they have to do.

When the coffers of the great banks of Europe were filled with the virgin gold of California and Australia, one of the first consequences was a desire on the part of countries in which silver was either a collateral standard of value with gold, or the sole standard of value, to discard the silver standard and adopt gold as the sole standard, involving in either case a large displacement of silver coinage and reserve, and a large infusion in its room of gold coinage and reserve. This result was exhibited in the mint operations both of France and England. In the former country silver retains its quality of legal tender in a modified degree; but the proportion of silver authorized by the Bank Charter Act of 1844 has long disappeared from the bullion reserve of the Bank of England, which now consists wholly of gold. It was one of the first resolutions of the German Empire, on the conclusion of the war of 1870-71, not only to make gold the sole standard, but to dislodge all the old silver money of the German States; and in the same connection it may be observed, that the director of the United States' Mint, in reporting £20,000,000 as the annual produce of the United States' mines, uses this fact as an argument for the immediate resumption of specie payment—or, in other words, that the American people, by a strenuous effort, should strive to keep as much of the bullion-product of their mines at home as may enable the whole currency of the Union to become either gold and silver, or of convertible gold value. This preference for the more precious metal as the sole standard of value, and for gold and silver coin as a medium of general circulation, may be expected to extend throughout the world in proportion as the produce of the mines may be increased; and in this respect alone there is a vast opening for the beneficial use both of gold and silver. It gives some idea of the immense service of bullion in the international exchanges, as well as in the replenishment of the internal metallic circulations, to observe that in the thirteen years 1858-70 the annual average registered import of gold and silver (real value) to the United Kingdom was £27,083,330, the average annual export £22,095,346; and that in the same thirteen years the average annual coinage of gold and silver in the Royal Mint was £4,854,661, or nearly equal to the annual excess of imports over exports of bullion, which flows in all this volume through London to and from every part of the globe—(*Statistical Abstract for United Kingdom*, 1872).

While the production of gold has declined of late years from the maximum attained after the Californian and Australian discoveries, the production of silver has begun to increase, and in the rapid development of minerals containing this metal, is generally expected to increase in the future. But it would seem premature from the facts of past experience to anticipate any permanent depreciation of the value of silver in relation to gold. The price of silver in the market of London from 1833 to 1873 ranged from 59d. to 62½d. per oz., and during that time fully maintained its standard value in par with that of gold—(*Table* of Messrs Pixley and Abell, bullion-brokers, London). But in the subsequent years a decline in the price of silver has occurred, and it fell in 1875 to 56d. per ounce. This may be the result of temporary causes, such as (1) the fact of £20,000,000 of German silver, displaced by the new gold coinage hanging over the market; and (2) a cessation of demand for India and China, which the exchanges of the East with Europe may at any time alter.

BULLS AND BRIEFS, Papal, are the two kinds of authoritative letters issued by the popes in their official capacity as head of the church, the bulls being the more important. They are distinguished from each other by several marks.

A *bull* is written on thick polished parchment, commonly in angular Gothic characters, and in Latin; it is always open; it commonly begins with the name of the Pope, but without adding any number (*e.g.*, Pius, not Pius IX.), then follows the term *episcopus*, then *servus servorum Dei*, then either the phrase *ad perpetuam rei memoriam*, or the greeting *in Domino salutem et apostolicam benedictionem*. It closes with the place and the date, which is commonly given according to the kalends, nones, or ides of the month and the year of the pope. The chief mark, however, of a bull is the seal. The popes use three kinds of seals—1, the signet-ring; 2, since the end of the 5th century, the *bulla*; 3, from the 13th century, the *annulus piscatoris*. A bull is sealed with the second, the *bulla*, and from this it derives its name. The *bulla* is a globular seal of lead; on the one side there is, in modern times, the heads of St Peter and St Paul, with the letters S. PE. and S. PA.; on the other side is the name of the Pope. Formerly the *bulla* often bore other impressions; the name of the Pope was always given, but sometimes the title *Papa* was impressed on the opposite side; sometimes a Scriptural image, such as the Good Shepherd. The popes evidently began to use this particular seal when, from the growing weakness of the empire, the temporal authority of the bishop of Rome began to be a real thing, and the popes assumed the consular dress and insignia; for the *bulla* had been used by the emperor of Constantinople, and its use was permitted to many of the great officers of state who were accustomed to act for the emperor. The *bulla* was the common imperial seal, and was used not merely by the emperors of the East, but also by the early German emperors, and even by some of the minor European sovereigns. It was sometimes made of gold, sometimes of silver, often of lead, and it was not until the earlier part of the Middle Ages that the leaden *bulla* became the distinctive mark of a Papal charter.

"Non auro, non argento, sacra Bulla refulget,
Insignit chartas plumbea forma sacras."

The word *bulla*—meaning first a bubble, then any kind of small ornament "*quasi inflata*," then a seal of a globular shape—came to be applied to a charter sealed with such a globular seal, and since the 15th century, exclusively to Papal letters of the first rank. If the bull is *in forma gratiosa* the seal is attached by threads of red and yellow silk; if *in forma rigorosa*, hemp is used. If the Pope issues a bull before he is enthroned, nothing is put on the seal, and the bull is commonly called *bulla blanca*. Before the time of Nicholas IV. such bulls were only valid if confirmed after enthroning. Since then they have been valid without confirmation. Consistorial bulls are issued after consultation with the consistory of cardinals, and are signed by all the cardinals consulted. Ducange (*Gloss. Med. et Inf. Lat.*) says that consistorial bulls are often sealed with the signet-ring.

A *brief* is not so important as a bull. It is written upon white paper, or thin parchment, in modern cursive characters, and is sometimes sent open, sometimes closed. It begins with the name of the Pope, then the title *Papa*, then the number of the Pope, then the phrase *ad perpetuam rei memoriam*, or *in Domino salutem et apostolicam benedictionem;* it ends with the name of the place, and the date (the day of the month, the year A.D., and the year of the Pope), and, finally, the words *sub annulo piscatoris*. The principal mark of the brief is its seal. It is sealed with red wax, with the signet called "the fisherman's ring," which dates from the 13th century, and bears a representation of St Peter fishing in a boat, and the name and the number of the Pope. The distinction between briefs and bulls is not much older than the 15th century. In the early Middle Ages the word *breve* was used to denote all sorts of *short* charters, and Ducange in his *Glossary* gives over a hundred different kinds of these. Papal bulls and briefs, like all other important legal instruments, are liable to be forged, and hence Roman Catholic jurists have made a special study of the various marks by which they are able to tell the age of a charter. The bulls and briefs of greatest importance have been published in *Bullaria* collections which have been put forth at different times under the authority of the church. The most important of those collections is the *Bullarium Magnum Romanum, a Leone Magno usque ad Benedictum XIV.*, Luxembourg, 1727–1758, 19 vols. fol., and its continuations.

BÜLOW, FRIEDRICH WILHELM (1755–1816), a Prussian general, was born at Falkenberg on the 16th February 1755. He entered the army at the age of fourteen, rose slowly, and in 1797 was placed at the head of a battalion. He took part in the campaigns of 1806–7, and in 1809 was made major-general and brigadier of infantry. On the renewal of the war against France in 1813 he took the field with the rank of lieutenant-general, was engaged in the battle of Möckern, and stormed the defences of Halle. He was victorious over Oudinot at Luckau and Grossbeeren, and over Ney at Dennewitz. He led the attack on the fortifications at Leipsic, and was conspicuous in the Prussian victory at Laon. To him also belonged the honour of closing the campaign by the capture of Montmartre. For his valuable services he was raised to the rank of general, and made Baron Dennewitz, with a handsome revenue. During the Hundred Days he commanded the fourth army corps, and by his rapid march contributed to Blücher's success at Waterloo. After the conclusion of the war he retired to Königsberg, where he died on the 25th February 1816.

BULWER, SIR HENRY LYTTON EARLE (1801–1872), statesman and diplomatist, created a peer, under the title of Baron Dalling and Bulwer, in 1871. See DALLING.

BULWER-LYTTON, SIR EDWARD GEORGE EARLE LYTTON (1805–73), brother of the preceding, created a peer, under the title of Baron Lytton, in 1866. See LYTTON.

BUNDELKHAND, an extensive tract, consisting partly of British districts and partly of native states, in the North-Western Provinces of India, lying between 23° 52′ and 26° 26′ N. lat., and 77° 53′ and 81° 39′ E. long. It is bounded on the N. by the Jumna, on the E. by the Bághalkhand or the Rewá state, on the S. by the Central Provinces, and the W. by the state of Gwalior.

It comprises the British districts of Hamírpur, Jalaun, Jhánsi, Lalatpur, and Bándá; the semi-independent states of Orchhá or Tehrí, Datiyá, and Samthar; and the following petty states held under grants from the British Government, viz.:—Ajegarh, Alípurá, Ashtgarhí Jágír, Tori-Fathpur, Bijná and Paharí Banká, Barondá, Báwaní, Berí, Bíhat, Bijáwar, Charkhárí, seven Chaubiyáná Kalinjár Jágírs, Chhatrapur, Garraulí, Gáuríhar, Jasú, Jigní, Khaniyá Dháná, Lughásí, Naigáon Ribahí, Panná, and Sarílá. Length of Bundelkhand—200 miles from S.E. to N.W.; breadth, 155 miles; area variously estimated from 18,099 to 23,817 square miles.

The surface of the country is uneven and hilly, except in the N.E. part, which forms an irregular plain cut up by ravines scooped out by torrents during the periodical rains. The plains of Bundelkhand are intersected by three mountain ranges, the Bindháchal, Panná, and Bander chains, the highest elevation not exceeding 2000 feet above sea-level. Beyond these ranges the country is further diversified by isolated hills rising abruptly from a common level, and presenting from their steep and nearly inaccessible scarps eligible sites for castles and strongholds, whence the mountaineers of Bundelkhand have frequently set at defiance the most powerful of the native states of India. The general slope of the country is towards the north-east, as indicated by the course of the rivers which traverse or bound the territory, and finally discharge themselves into the Jumna.

The principal rivers are the Sindh, Betwá, Ken, Baighin, Paisuní, Tons, Pahuj, Dhasán, Bermá, Urmal, and Chandrawál. The Sindh, rising near Sironj in Málwa, marks the frontier line of Bundelkhand on the side of Gwalior. Parallel to this river, but more to the eastward, is the course of the Betwá. Still further to the east flows the Ken, followed in succession by the Baighin, Paisuní, and Tons. The Jumna and the Ken are the only two navigable rivers. Notwithstanding the large number of streams, the depression of their channels and height of their banks render them for the most part unsuitable for the purposes of irrigation,—which is conducted by means of *jhils* and tanks. These artificial lakes are usually formed by throwing embankments across the lower extremities of valleys, and thus arresting and accumulating the waters flowing through them. Some of the tanks are of great capacity; the Barwá Ságar, for instance, is 2½ miles in diameter. Diamonds are found, particularly near the town of Panná, in a range of hills called by the natives Band-Ahil.

The mines of Mahárájpur, Rájpur, Kimerá, and Gadásiá contain the finest diamonds; one dug from the last is reputed to be the largest in the world. It was kept in the fort of Kalinjas among the treasures of Rájá Himmat Bahádur. In the reign of the Emperor Akbar the mines of Panná produced diamonds to the amount of £100,000 annually, and were a considerable source of revenue, but for many years they have not been so profitable.

The tree vegetation consists rather of jungle or copse than forest, abounding in game which is preserved by the native chiefs. There are also within these coverts several varieties of wild animals, such as the tiger, leopard, hyena, wild boar, *nilgái*, and jackal.

British Bundelkhand contains a population of 2,161,495 souls. The total population of Bundelkhand, British and native, has been estimated at 2,260,714. The people represent various races. The Bundelás,—the race who gave the name to the country,—still maintain their dignity as chieftains, by disdaining to cultivate the soil, although by no means conspicuous for lofty sentiments of honour or morality. An Indian proverb avers that "one native of Bundelkhand commits as much fraud as a hundred Dandis" (weighers of grain, and notorious rogues). About Datiyá and Jhánsí the inhabitants are a stout and handsome race of men, well off and contented.

The prevailing religion in Bundelkhand is Hinduism.

The principal crops are wheat, *joár*, cotton, indigo, sugar-cane, a red dye called *ách*, various kinds of millets and pulses, and *mahuá* (*Bassia latifolia*). Carpets are manufactured at Jhánsí, and paper at Kalpi. Bamboo and *Acacia catechu* from the jungles form important articles of trade. Principal routes—(1), from Allahábád to Nasírábád through Bándá; (2), from Fathipur to Ságar through Bándá; (3), from Cawnpur to Jabalpur; (4), from Cawnpur to Guná through Kálpí and Jhánsí; (5), from Bándá to Gwalior; and (6) from Agra to Ságar. The Jabalpur line of the East Indian Railway passes through the native states of Bundelkhand. Principal towns,—Kálpí, Bándá, Jhánsí. Datiyá, Urchá, Jalaun, Chhatrapur, Mahobá, and Tehárí. The climate of Bundelkhand is sultry and unhealthy.

HISTORY.—Chandra Varmá, chief of the Chandel Rájputs, appears to have established the earliest paramount power in Bundelkhand towards the close of the 9th century A.D. Under his dynasty the country attained its greatest splendour in the early part of the 11th century, when its Rájá, whose dominions extended from the Jumna to the Nerbudda, marched at the head of 36,000 horse and 45,000 foot, with 640 elephants, to oppose the invasion of Mahmúd of Ghazní. In 1183 the Chandel dynasty was overthrown by Pirthwi Ráj, the ruler of Ajmir and Delhi, after which the country remained in ruinous anarchy until the close of the 14th century, when the Bundelás, a spurious offshoot of the Garhwá tribe of Rájputs, established themselves on the right bank of the Jumna. One of these took possession of Urchá by treacherously poisoning its chief. His successor succeeded in further aggrandizing the Bundelá state, but he is represented to have been a notorious plunderer, and his character is further stained by the assassination of the celebrated Abulfazl, the prime minister and historian of Akbar. Jajhar Sinh, the third Bundelá chief, unsuccessfully revolted against the court of Delhi, and his country became incorporated for a short time with the empire. The struggles of the Bundelás for independence resulted in the withdrawal of the royal troops, and the admission of several petty states as feudatories of the empire on condition of military service. The Bundelás, under Champat Rái and his son Chhatra Sál, offered a successful resistance to the proselytizing efforts of Aurungzebe. On the occasion of a Mahometan invasion in 1732, Chhatra Sál asked and obtained the assistance of the Marhattá Peshwá, whom he adopted as his son, giving him a third of his dominions. The Marhattás gradually extended their influence over Bundelkhand, and in 1792 the Peshwá was acknowledged as the lord paramount of the country. The Marhattá power was, however, on the decline; the flight of the Peshwá from his capital to Bassein before the British arms changed the aspect of affairs, and by the treaty concluded between the Peshwá and the British Government, the districts of Bándá and Hamírpur were transferred to the latter. Two chiefs then held the ceded districts, Himmat Bahádur, the leader of the Sanyásis, who promoted the views of the British, and Shamsher, who made common cause with the Marhattás. In September 1803, the united forces of the English and Himmat Bahádur compelled Shamsher to retreat with his army. In 1809 Ajaigarh was besieged by a British force, and again three years later Kalinjár was besieged and taken after a heavy loss. In 1817, by the treaty of Poonah the British Government acquired from the Peshwá all his rights, interests, and pretensions, feudal, territorial, or pecuniary, in Bundelkhand. In carrying out the provisions of the treaty, an assurance was given by the British Government that the rights of those interested in the transfer should be scrupulously respected, and the host of petty native principalities in the province is the best proof of the sincerity and good faith with which this clause has been carried out. During the mutiny of 1857, however, many of the chiefs rose against us, especially the Rání of Jhánsí.

BUNDI, a Rájput state of India, under the political superintendence of the Government of India through its agent in Rájputáná, situated between 24° 58′ and 25° 55′ N. lat., and 75° 23′ and 76° 36′ E. long. It is bounded on the N. by the native states of Jaipur and Tonk; on the E. by the state of Kotal; on the S. by Sindhiá's territories; and on the W. by the state of Udaipur. Many parts of the state are wild and hilly, inhabited by a large Míná population, a race of robbers. Two rivers, the Chambiá and the Níj, water the state; the former is navigable by country boats. Area, 2291 square miles; population in 1871–72, 224,000, or 97 to the square mile. The chieftain and the greater part of his followers are Rájputs. Principal crops—Indian corn, *joár*, wheat, pulses, and oil-seeds. Iron is found. The chief's annual income amounts to £50,000, derived from land-tax levied both in kind and money, and from customs. Thefts and petty robberies are still of frequent occurrence. Our political relations with Bundí commenced in 1804 during the Marhattá war, and in 1818 its chief accepted our protection. The present ruler has managed the state for the last fifty years, and done much to improve the condition of the people. Bundí pays an annual tribute of £4000 to the British Government.

BUNKER HILL, a small elevation, 110 feet high, in the town of Charlestown, 1 mile N. of Boston, in Massachusetts. One of the most celebrated battles in the war of American independence was fought here on the 17th of June 1775. The British remained masters of the field after a long and bloody contest. A commemorative obelisk, 221 feet high, has been erected in the centre of the grounds included within the redoubt on Breed's Hill. See BOSTON, vol. iv. p. 72.

BUNSEN, CHRISTIAN CHARLES JOSIAS, BARON VON (1791–1860), was born 25th August 1791, at Corbach, an old town in Waldeck, one of the the smallest of German principalities. He was of honourable but humble origin. His father, to eke out the scanty subsistence provided by his few acres of land, had entered a regiment "granted" to Holland by the prince. Without promotion or encouragement, he attended conscientiously to the drudgery of his post during twenty-nine long years, to return at last, in 1789, a widower, with broken health and a miserable pension. Brighter days were in store for him through the affections of his second wife and the birth of Christian. It is on record, how joyous were the evenings in that old-fashioned Corbach home, when, after reading a chapter from the family Bible, and devoutly praying with his household, the kindly old man loved to prune, by pithy remarks and snatches of proverbial lore, the redundant enthusiasm and all-embracing fervour of his son. To the latter, success and a host of fond admirers seem from the first never to have been wanting. Nor did humility of demeanour, exquisite sympathy with all men, and an almost unexampled power of work ever fail him. The Corbach grammar school was brilliantly passed, and after it a first year of university studies, at Marburg, devoted to divinity. But Göttingen in those days attracted all superior minds, and the youth of eighteen found himself on his way thither with the last savings from his father's purse, intent upon appeasing his desire for those wider regions of philological and historical learning in which he knew his strength must lie. Again all avenues of outward success opened to the unpretending student; although so young he was entrusted with lessons at the Latin school, and soon after with the office of private tutor to W. C. Astor, only son of the well-known merchant king of New York.[1] Bunsen soon became the acknowledged though unobtrusive centre of a chosen band of students, few only of whom have failed to attain that reputation to which their abilities seemed to call them,

[1] Mr W. C. Astor, "the landlord of New York," as he has been called, died in November 1875.

or that degree of public usefulness to which in an hour of genuine enthusiasm they one and all vowed to aspire. "Right royal in all his ways," as a poet has fitly described him, he sympathized with the favourite pursuits of each, wrestled with all, made them to love each other, and held high among them the ideals of youth and of science. It was quite a day of rejoicing in Göttingen when Bunsen had won the university prize essay of the year 1812 by a treatise on the *Athenian Law of Inheritance*, and again a few months later when the university of Jena granted him, unsolicited, the honorary degree of doctor of philosophy.

The time had now come for Mr Astor to travel. Bunsen had seen little of the world before then. Only one journey had he made, but that one was to Weimar, and in company with Arthur Schopenhauer, one of his Göttingen acquaintances, a man of genius, whose fate it has been to live unknown and to become after death not famous only, but the founder of a numerous and turbulent school of metaphysicians. Bunsen was introduced to Goethe, and bore away the impress of the society that assembled around the great poet. In 1813, a journey was undertaken to South Germany, during which Mr Astor was well pleased to see his friend revelling in the company of choice spirits at each centre of intellect, and shared in his exultation over the crushing blow that had fallen upon Napoleon at Leipsic. Some months later they separated at Göttingen, Astor to return to New York, with an understanding that they would meet for further travel two years later, and Bunsen to resume his studies which had lost nothing of their vast range. It seemed to Bunsen a purpose not exceeding the limits of a man's life to comprehend the history of all Teutonic races in religion, laws, language, and literature. That was the heroic age of comparative philology; and thus we see Bunsen, who had read Hebrew when a boy, plunging into Arabic at Munich, Persian at Leyden, and Norse at Copenhagen, as opportunities offered for each.

At the close of 1815 Bunsen found his way to Berlin, to lay before Niebuhr the historian what was then already a many years' plan of learned inquiry. This step led to important consequences in the life of Bunsen. Niebuhr not only approved of the Titanic scheme, and hoped that Prussia, in which all the hope of Germans then began to be centred, would in time find money for assisting it, but so powerful an impression did he receive on that occasion, that when they met again two years later, Niebuhr, having meanwhile become Prussian envoy to the Papal court, exerted all his influence to draw Bunsen into official life. Of the two intervening years it will suffice to relate that they had been spent by Bunsen in assiduous labour among the libraries and collections of Paris and Florence, whither the hope of meeting his former pupil, Mr Astor, had led him; and that he contracted during his stay in the capital of France a love for the peculiar graces of French genius which never left him through life.

Fascinated by the condescending friendship of Niebuhr, by the glories of Rome, and also by the charms of English society, Bunsen continued his stay in that city. In July 1817 he married Miss Waddington, eldest daughter and co-heiress of Mr B. Waddington of Llanover, Monmouthshire. Even then his purposes in life remained purely scientific. Little did he dream that the Eternal City was to become his home for twenty-one years, or that one of the most difficult problems of European diplomacy would there be entrusted to his hands.

When Niebuhr obtained the consent of his Government for the appointment of Bunsen as secretary of the Roman embassy, negotiations were being actively carried on between Berlin and Rome for a new establishment of the Papal Church in the Prussian dominions. This had become necessary, since 1815, by the addition of several millions of Catholics to the population of that mainly Protestant country, of which they now formed no less than two-fifths. An agreement was the fruit of these labours, by which the king of Prussia allowed the publication within his dominions of a Papal bull (called *De salute animarum*), circumscribing the Catholic dioceses, and determining the position of the Romanist hierarchy. During this period of initiation into the mysteries of Papal statecraft, Bunsen had occasion to learn that the Vatican began, under the fostering care of the Jesuit order, to revive from the inanition into which the French Revolution and its effects had thrown it. So universal and so strong was the wave of reaction in those days throughout Europe, that Protestant and Catholic rulers agreed in the conviction that of all conservatism the apex and supreme exponent must be the Pope, as representing "the most ancient succession of sovereigns," as "upholder of things as they are." Considering themselves the Pope's born allies, they closed their eyes to that stealthy encroachment of absolute Romish power into the dioceses within their territory with which the present generation is becoming acquainted in America as well as in Europe. Bunsen was among those who first discerned the coming danger. To direct official attention towards it, to ward it off by fairness and impartiality towards his Catholic fellow-subjects, to preserve religious peace in his country, thenceforward became the main object of his official labours.

At first his success was great. In Berlin the king and his minister, and at Rome each successive Pope and his cardinal secretary, bestowed upon him every mark of confidence and even of affection. King Frederick William III. had made his acquaintance as early as 1822 during a brief stay at Rome, and had taken unwonted pleasure not only in his conversation generally, but even in the outspoken but elegant frankness with which Bunsen defended his views when at variance with one or two of his sovereign's favourite theories. He evinced his appreciation of the youthful diplomatist by desiring him to undertake the legation after Niebuhr's retirement from his office.

In the Papal Government, also, Bunsen's honest endeavours to preserve a good understanding were readily acknowledged, and formed the basis for one of the rarest life friendships, and yet a most real one, with Monsignor Capaccini, the confidential adviser of successive Popes in foreign affairs, who never swerved from his principle of both receiving and meeting every communication of the Prussian envoy with equal trust and truthfulness.

A few words will explain the causes which eventually led to a failure of Bunsen's pacific efforts. Marriages between Romanists and Protestants (or so-called mixed marriages) had formerly been of rare occurrence in Prussia. Before the iron will of Frederick the Great, the naive demands of the hierarchy of Silesia—the chief of which is a promise on oath that all children shall be brought up as Catholics—had dwindled into a passive attitude on their part. After the accession of Rhineland and Westphalia to the Prussian monarchy had added to the frequency of such marriages, it was truly fortunate that a prelate of moderate views in matters ecclesiastical and a good patriot—Count Spiegel—held the archiepiscopal see of Cologne (1825). With him, who forbade processions of his own accord as leading to immorality, and who favoured a more enlightened education of candidates for holy orders, an arrangement which would leave the consciences of spouses and priests unviolated was practicable. It was easily obtained by Bunsen's personal negotiation with the archbishop. The other Prussian bishops also consented; but such was the slothfulness of the absolute king's Government, that the death of that wise archbishop (1835) occurred before its ratification, and such their blindness to reality that they

offered to promote a narrow-minded ascetic, Baron Droste, to the vacant post. "Is your king mad?" bluntly exclaimed the cardinal-secretary, whilst hastening to accept, on the part of the Vatican, the proffered tool of Papal aggression! Before two years had passed the religious strife was in a blaze everywhere,—Jesuit advisers more eagerly listened to at Rome, Prussian bishops all but unanimous in their opposition against moderate counsels, and (so the Government was informed) the leadership of these machinations against the internal peace of Prussia entrusted to members of that uniformly Ultramontane body, the Belgian bishops. In this extremity Bunsen was again summoned to Berlin from his post. It is difficult at this distance of time to discern how far the advice he may have given was founded upon too sanguine a view both of the power of an absolute king, unaided by an emancipated public opinion, a free press, or a parliament, and of the intensity of the agitation raging in Catholic districts. But this much is known that, when the seizure of the chief offender in his archiepiscopal palace at Cologne was resolved upon, Bunsen understood that the archbishop would forthwith be placed before the ordinary judges of the country for disobedience to its laws. This was never done, and the seizure was so mismanaged that the incriminating documents are said to have been destroyed before the judicial authorities had set foot in the palace. Thus a complete failure was the result of this very unsafe step. The Government thought it easier to leave Bunsen unsupported when, after his return to Rome, he courageously attempted to convince the Vatican of the archbishop's guilt, and, in the hope of burying the matter in oblivion, they accepted Bunsen's offer of resignation, in April 1838. It may not be irrelevant to mention here that the king's successor, Frederick William IV., on his elevation to the throne in 1840, released Baron Droste from prison. This romantic king established his policy towards the Vatican on the principle of granting liberty of action to the Papal power,—a liberty so well employed both before and since the revolution of 1848, that at this moment (1876) all the energies of a powerful chancellor and a united Germany are taxed to the utmost to find a basis for harmonious coexistence between modern states and the hierarchy of Rome.

When Bunsen left the Eternal City a politically disappointed man, he was able, nevertheless, to look back upon a term of years filled with everything that could adorn life—intense domestic contentment, intimacy with distinguished men of every nation who had sojourned in Rome during his twenty-one years' residence there, success in establishing institutions which, like the Archæological Institute, the German Hospital, and the Protestant chapel, have outlived his stay, experience in public affairs, and a deepening of his religious convictions. Religion had become the centre of his most tender emotions, of his intellectual activity, of his practical aspirations. To restore to the Bible that place in the households of his country which it had possessed in the first generations after the Reformation, to revive the knowledge and the love of the German reformers' hymns, to give his people such a Book of Common Prayer, resting upon the liturgies of all Christian ages, as would help congregations in "presenting themselves a living sacrifice," to rekindle the fervour of other days for works of self-devotion and charity, to work out a Christian philosophy of history,—such were the purposes to which he devoted his happiest and best hours in each succeeding year. Whilst he was at Rome a book of ancient hymns and a liturgy were printed.

Bunsen always looked back in later years upon his Roman time as men are apt to remember their college days. Right joyous had been his intercourse with artists such as Thorwaldsen, Rauch, Wolff, Cornelius, Schnorr, Overbeck, Schinkel, Felix Mendelssohn. He had become one of the best-informed men among art-collections, and was so attracted by the charms of Roman topography as to surrender to the temptation of contributing volumes to the German *Description of Rome*.

Few strangers have ever lived on terms of greater intimacy with Italians, or possessed a more entire command of their language than Bunsen. He was a believer in their national revival and political future at a time when Italy was "a geographical expression" only and when her art treasures and her blue sky were her only acknowledged qualities. Among Americans Mr Ticknor; among Russians Italinsky, Joukovsky, and Al. Tourgenieff; among Frenchmen the Duc de Blacas, Comte de St Aulaire, Chateaubriand, Champollion, Ampère, and others became his friends. But his most cherished intercourse was with English visitors and residents,[1] to which he owed an acquaintance with British life such as has rarely been possessed by any foreigner who never had set foot in this country.

Towards England, then, did he turn his face in 1838 to enjoy the leisure occasioned by his removal from the Capitol, and in England, except when he held a brief diplomatic appointment as Prussian ambassador to Switzerland from 1839 to 1841, the remainder of his official life was spent.

Between the Crown Prince of Prussia and Bunsen a very close intimacy had sprung up ever since they met at Berlin in 1828. They were attracted to each other by similarity of literary tastes, of poetic temperament, and of religious aspiration. In their enthusiasm for each other, the prince as well as the public servant fondly hoped, year after year, that diversity of character and of self-grown conviction, however marked, would tend rather to compensate defects than to disturb harmonious action. Their correspondence lately published (in part) by Ranke, the historian, shows the truthfulness and the durability of this remarkable friendship, and helps to explain why its results were not commensurate to the moral worth and intellectual capacity of the men who were united by it.

The new king had no sooner ascended the throne under the name of Frederick William IV. than he contemplated the erection of an Anglo-Prussian bishopric at Jerusalem, intended to represent European Protestantism as a united power, and to give a rallying point to Protestant missions in Syria and Palestine. The time seemed propitious for this fantastic scheme. The four allied powers, under the leadership of Great Britain, had reinstated the sultan in the possession of Syria. The Turkish Government would therefore readily grant a similar representation to Protestant churches to that possessed by Orthodox Greeks and Roman Catholics. King Frederick William summoned Bunsen to his capital, and instructed him to negotiate in London the establishment of such a bishopric on Mount Zion. In an incredibly short time (June to November 1841) Bunsen succeeded in bringing it about, with the English Government's courteous assent, and the energetic furtherance of the archbishop of Canterbury and the bishop of London, Prussia paying in a capital which secured one-half of its endowment, whilst the other half was to be raised in England. Much suspicion was felt and opposition raised against any association of the Church of England with German Protestantism, in both countries alike, though from

[1] One of these, and a very valued correspondent of Bunsen, was Lord Clifford, well known as a devout Roman Catholic. He had made the struggle between Berlin and the Vatican the subject of earnest study, and was enabled by his high social position to obtain from documents a more dispassionate view of it than, perhaps, any contemporary witness of the events. His testimony, therefore, expressed in a letter to Bunsen of 31st March 1838, may claim a place in this sketch. Lord Clifford writes,—"Your public career here has been of benefit to the peace of Europe."

opposite motives. To Bunsen this "special mission" brought in a rich harvest of friendly feeling among the leaders of both parliamentary parties, so that when Queen Victoria selected his name out of three proposed by the chivalrous courtesy of the Prussian king for the post of Prussian ambassador, he found himself well received by all classes of English society. The king's visit to England in February 1842, as sponsor to the Prince of Wales, helped to prove the earnest desire of Prussia to seek the friendship of Great Britain. An event, however, which directed the eyes of the British public even more to Bunsen than royal favour was the publication of Arthur Stanley's *Life of Dr Arnold*, in whose private letters an admiration amounting almost to enthusiasm for his German friend was expressed with a fervour unusual to Arnold's stately reserve. Although not palatable to the growing ritualistic school, and not always considered a safe theologian by the partizan leaders of the Low Church, Bunsen retained to the last the affection of the British nation, among whom he spent thirteen eventful years.

In the year 1844 his advice was asked by the king on the constitutional changes,—from absolutism to a representative government,—upon which Prussia, although in a first-rate financial military and administrative condition, found herself irresistibly constrained to enter. His advice, though studiously conservative, was considered of too sweeping a nature, and the king contented himself in 1847 with convoking an assembly composed of all members of the eight provincial diets of the monarchy, and clothed with scarcely any constitutional powers.

On the question of church organization, also, the king and his friend were fated to disagree more strongly than they had expected. Bunsen's views had developed into a system essentially Presbyterian, though with an Episcopal headship. He held up the constitution of the Episcopal Church of America as, perhaps, the best type to follow, because it contained personal rule organically allied to the free power of the laity. He recommended these ideas to his countrymen as well as to his sovereign in a book entitled *The Church of the Future*, which has not been without influence in the church constitution now (1876) about to become law in Prussia.

The king's expectations of a quiet time for maturing his work of reconstruction in church and state were rudely broken in upon by the French Revolution of February 1848. Bunsen's warning voice had been raised in vain; the discontent of the educated classes helped to weaken the distracted councils of Frederick William IV., and, though a constitution was eventually promulgated, Prussian politics succumbed under the tutelage of the Austrian premier, Prince Schwarzenberg, in 1849 Bunsen's diplomatic labours were mainly directed to settle, as German commissioner, the dispute with Denmark about the duchies of Holstein and Schleswig, Great Britain having offered her mediation. In these duchies a strong agitation of several years' standing had roused the German population, which occupies the whole of the former and part of the latter, to oppose the centralizing tendencies of the Danish Government. During the troubles of March 1848 they had taken up arms against Denmark and found assistance in Germany, then for the first time aspiring again to the position of a national power. This disturbance of the public peace of Europe was, however, regarded with so much disfavour by all powers, and secretly also by the sovereigns of Prussia and Austria, that the Danes obtained, in 1852, a European protocol, which reversed the political autonomy of the two duchies, and settled the crown of Denmark, after the death of the king and his son, upon Prince Christian of Glücksburg. It was the fate of Bunsen to be obliged to add his signature to this protocol, although it contained an abrogation of those "constitutional rights of Schleswig and Holstein," upon which he had dilated in a *Letter to Viscount Palmerston*, printed in April 1848.

The unity of Germany was another of those wishes in which Bunsen and his royal patron had been one ever since the beginning of their acquaintance, and yet found themselves widely apart when the question came to be practically tested. The king sincerely aimed at the resuscitation of the venerable German empire, fancying that the leadership within the federation of sovereigns might be divided between Austria and Prussia, yet so as to leave a kind of ceremonial primacy to the former. Enlightened Germans, on the contrary, had then already arrived at the conviction that the leadership must be in Prussian hands. Austria, hampered as she is by the numerical preponderance of non-German populations, and the divergence of her interests from those of Germany, should, they thought, take her place within a wider federation. Gradually and almost imperceptibly did this truth work its way through time-honoured tradition. Bunsen was one of its most eloquent apostles, in his official correspondence as well as in pamphlets published in 1848. Several times he was sanguine enough to believe such a policy to be permanently grasped in Berlin, but the king's vacillating temper and his adherence to tradition refused to be wrought upon beyond the approval of half-measures. Thus the opportunity was lost, the potentiality of the Prussian military power neglected, and a gnawing disappointment left in the minds of the best patriots throughout Germany.

With small hopes, and with no other wish but to serve as long as possible a sovereign whose friendship and confidence had outlived their former agreement on matters of religion and policy, Bunsen continued in the thankless task of representing Prussia after the downfall of those proud hopes that had pictured forth a revival of the German nationality under Prussian leadership. His main object, pursued under every difficulty, and seized with energy on every favourable opportunity, was to dissociate the policy of Berlin from that of St Petersburg and Vienna, and to draw closer whatever bonds of common sentiment or interest existed between the English and German communities. He was not tardy, therefore, in advising his royal master in an anti-Russian sense when the Crimean war began. As had so often been the case, the king's understanding went along with much that Bunsen wrote, and hopes were entertained that a Prussian participation in the war, containing the threat of an invasion of the north-western frontier of Russia, would force that country into compliance with the demands of the Western powers. But traditional policy again prevailed, mixed with the king's unconquerable aversion to Napoleon III., and his growing mistrust of Lord Palmerston's political principles. The alliance of the Western powers was declined, Prussia preserved towards her Eastern neighbour what is technically called a "benevolent neutrality," and the king accepted Bunsen's proffered resignation of his post as minister in London in April 1854.

The remaining years of Bunsen's life were spent in almost unbroken literary labours, first at a villa on the banks of the Neckar, near Heidelberg, and at the last in Bonn. In the politics of the day his interest was as keen as ever, and readily did he give his advice when advice was asked, as happened frequently on the part of the prince and princess of Prussia then residing at Coblentz, who have since risen to the exalted position of emperor and empress of Germany. But declining health determined him not to enter the Prussian Lower House, in which a seat was offered him by the liberal majority in the city of Magdeburg. His *Signs of the Times*, however, an elaborate pamphlet, published in 1856, acted like a first trumpet-call

against the aggressive demeanour of the reactionary clique, who were utilizing, in the interests of despotism and obscurantism, the horror of revolutionary outbreaks then felt by the quiet middle classes of Germany. Its publication prepared the way, more perhaps than any other event, for that rise of liberal opinion in Prussia which showed its power in the next reign.

Twice only was Bunsen tempted away from his Heidelberg retreat to show himself at Berlin,—once, at the king's desire and as his guest, in September 1857, to attend the meeting of the Evangelical Alliance, in the main objects of which he sympathized as warmly as King Frederick William IV. On that occasion, and after much confidential intercourse, the two friends parted never to meet again on this side of the grave. One of the last papers signed by the king before his mind gave way in October of that year was that which raised Bunsen to the rank of baron, and conferred upon him a life peerage. In 1858 the Regent (now Emperor) William having addressed a special request to Baron Bunsen not to fail him at the opening of his first parliament, he took his seat in the Upper House, and supported actively during a brief autumn session, but without ever making a speech, the regent's new cabinet, of which several of Bunsen's political and personal friends were members.

Literary work was, however, the centre of his life throughout that time. Two discoveries of ancient MSS. which occurred during his stay in London, containing, the one a shorter text of the *Epistles of St Ignatius*, and the other an unknown work *On all the Heresies*, by Bishop Hippolytus, had already given him an opportunity for enlarging upon the history of the first centuries of the Christian Church. He now concentrated all his efforts upon producing a Bible translation with commentaries that would open the sacred volumes afresh to the understanding and the hearts of a generation gradually estranged from them. Whilst this "*Bible-work*," was in preparation, and to pave the way for its reception, he printed a book considered by many to contain his most matured thoughts, under the title of *God in History*. The progress of mankind, he contends, marches parallel to the conception of God formed within each nation by the highest exponents of its thought. At the same time he carried through the press, ably assisted by Mr Birch the Egyptologist, the concluding volumes of his work (published in English as well as in German) *Egypt's Place in Universal History*—containing a reconstruction of Egyptian chronology, together with an attempt to determine the relation in which the language and the religion of that country stands to the development of each among the more ancient non-Aryan and Aryan races, between which its curious civilization seems to have formed a kind of connecting link. Those who desire to know Bunsen's ideas on this subject may find them most fully developed in two volumes published in London before he quitted England—*Outlines of the Philosophy of Universal History as applied to Language and Religion*. It will be seen even from this brief outline that his "first love" had never lost its hold upon him, and that the desire "to trace the firm path of God through the stream of ages" continued his purpose for life.[1]

But asthma and all other concomitants of a malady that had announced itself for years now began to disturb, not the mental alacrity or the spirits of Bunsen himself, but the hopes of his family and those among his friends who had imagined that he would be allowed to complete the works undertaken. Ordered to spend his winters in a more genial climate, he repaired to Cannes in 1858 and 1859, not without a lengthened visit to Paris, where he revelled, as in younger days, in the contact with men of learning. In May 1860 he purchased a house in Bonn, hoping against hope, pushing forward the publication of his *Bibel-Werk*, and even preparing lectures for students upon those subjects which he had most at heart. But the hand of death was upon him. He thanked God daily for teaching him how to support pain at the close of a life so eminently exempt from bodily suffering. And whenever, in the closing weeks of his existence on earth, a relaxation of asthma ensued, fervent prayer flowed from his lips, powerful attestation of his religious belief, loving exhortation to those from whom he was soon to be removed. Baron Bunsen died on November 28, 1860, and lies buried in the churchyard of Bonn, not far from the grave of his early friend and benefactor Niebuhr.

"Let us walk in the light of the Lord" (Isa. ii. 5) is the text which Baroness Bunsen placed on his tomb. One of his last requests having been that she would write down recollections of their common life, she published his *Memoirs* in 1868, which contain much of his private correspondence. The German translation of these *Memoirs* has added extracts from unpublished documents, throwing a new light upon the political events in which he played a part. Baron Humboldt's letters to Bunsen were printed in 1869, and Ranke published in 1873 a large portion of the correspondence that passed between King Frederick William IV. and Bunsen. (G. V. B.)

BUNTING, a word of uncertain origin, properly the common English name of the bird called by Linnæus *Emberiza miliaria*, but now used in a general sense for all members of the family *Emberizidæ*, which are closely allied to the Finches (*Fringillidæ*), though, in Professor Parker's opinion, to be easily distinguished therefrom—the *Emberizidæ* possessing what none of the *Fringillidæ* do, an additional pair of palatal bones, "palato-maxillaries." It will probably follow from this diagnosis that some forms of birds, particularly those of the New World, which have hitherto been commonly assigned to the latter, really belong to the former, and among them the genera *Cardinalis* and *Phrygilus*. The additional palatal bones just named are also found in several other peculiarly American families, namely, *Tanagridæ*, *Icteridæ*, and *Mniotiltidæ*—whence it may be perhaps inferred that the *Emberizidæ* are of Transatlantic origin. The Buntings generally may be also outwardly distinguished from the Finches by their angular gape, the posterior portion of which is greatly deflected; and most of the Old-World forms, together with some of those of the New World, have a bony knob on the palate—a swollen out growth of the dentary edges of the bill. Correlated with this peculiarity the maxilla usually has the tomia sinuated, and is generally concave, and smaller and narrower than the mandible, which is also concave to receive the palatal knob. In most other respects the Buntings greatly resemble the Finches, but their eggs are generally distinguishable by the irregular hair-like markings on the shell. In the British Islands by far the commonest species of Bunting is the Yellow Hammer (*E. citrinella*), but the true Bunting (or Corn-Bunting, or Bunting-Lark, as it is called in some districts) is a very well-known bird, while the Reed-Bunting (*E. schœniclus*) frequents marshy soils almost to the exclusion of the two former. In certain localities in the south of England the Cirl-Bunting (*E. cirlus*) is also a resident; and in winter vast flocks of the Snow-Bunting (*Plectrophanes nivalis*), at once recognizable by its pointed wings and elongated hind-claws, resort to our shores and open grounds. This last is believed to breed sparingly on the highest mountains of Scotland, but the majority of the examples which visit us come from northern regions, for it is a species which in summer

[1] It may be mentioned that Bunsen contributed the article LUTHER, one of the finest biographies of the great Reformer, to the eighth edition of the present work, 1857.

inhabits the whole circumpolar area. The Ortolan (*E. hortulana*), so highly prized for its delicate flavour, occasionally appears in England, but this island seems to lie outside its proper range. On the continent of Europe, in Africa, and throughout Asia, many other species are found, while in America the number belonging to the family cannot at present be computed. As already stated, the beautiful and melodious Cardinal (*Cardinalis virginianus*), commonly called the Virginian Nightingale, must be included in this family, as also the Bobolink (*Dolichonyx oryzivorus*), a bird for sapidity perhaps surpassing the far-famed Ortolan, and intimately connecting the *Emberizidæ* with the *Icteridæ*. Whether any species of the family inhabit the Australian Region is as yet doubtful, but it would seem possible that several genera of Australian birds hitherto classed with the *Fringillidæ* may have to be assigned to the *Emberizidæ*. (A. N.)

BUNTING, JABEZ, D.D., a distinguished Wesleyan minister, who exerted an influence in his denomination second only to that of John Wesley himself, was born at Manchester 13th May 1779, and died on the 16th June 1858. He was educated at the grammar school of his native town. At the age of nineteen he began to preach, and a year later (1799) he became a member of the Conference. He continued in the active discharge of his ministerial duties for upwards of fifty-seven years—his successive spheres of labour being Manchester, Liverpool, and London. In 1834 he was appointed president of the newly-founded Wesleyan theological college, and in this position, which he held till his death, he succeeded in materially raising the standard of education among Wesleyan ministers. He was four times chosen to be president of the Conference, was repeatedly secretary of the "Legal Hundred," and for eighteen years was secretary to the Wesleyan Missionary Society. In these and other offices he found ample scope for that great natural sagacity and power of administration which did so much for the consolidation and extension of the Wesleyan denomination. Dr Bunting was a popular preacher, and an effective platform speaker. Two volumes of his sermons were published posthumously in 1862. The first volume of a memoir, by his son, appeared in 1860.

BUNYAN, JOHN (1628–1688), the most popular religious writer in the English language, was born at Elstow, about a mile from Bedford, in the year 1628. He may be said to have been born a tinker. The tinkers then formed a hereditary caste, which was held in no high estimation. They were generally vagrants and pilferers, and were often confounded with the gipsies, whom in truth they nearly resembled. Bunyan's father was more respectable than most of the tribe. He had a fixed residence, and was able to send his son to a village school where reading and writing were taught.

The years of John's boyhood were those during which the Puritan spirit was in the highest vigour all over England; and nowhere had that spirit more influence than in Bedfordshire. It is not wonderful, therefore, that a lad to whom nature had given a powerful imagination and sensibility which amounted to a disease, should have been early haunted by religious terrors. Before he was ten, his sports were interrupted by fits of remorse and despair; and his sleep was disturbed by dreams of fiends trying to fly away with him. As he grew older, his mental conflicts became still more violent. The strong language in which he described them has strangely misled all his biographers except Mr Southey. It has long been an ordinary practice with pious writers to cite Bunyan as an instance of the supernatural power of divine grace to rescue the human soul from the lowest depths of wickedness. He is called in one book the most notorious of profligates; in another, the brand plucked from the burning. He is designated in Mr Ivimey's *History of the Baptists* as the depraved Bunyan, the wicked tinker of Elstow. Mr Ryland, a man once of great note among the dissenters, breaks out into the following rhapsody:—"No man of common sense and common integrity can deny that Bunyan was a practical atheist, a worthless contemptible infidel, a vile rebel to God and goodness, a common profligate, a soul-despising, a soul-murdering, a soul-damning, thoughtless wretch as could exist on the face of the earth. Now be astonished, O heavens, to eternity! and wonder, O earth and hell! while time endures. Behold this very man become a miracle of mercy, a mirror of wisdom, goodness, holiness, truth, and love." But whoever takes the trouble to examine the evidence will find that the good men who wrote this had been deceived by a phraseology which, as they had been hearing it and using it all their lives, they ought to have understood better. There cannot be a greater mistake than to infer from the strong expressions in which a devout man bemoans his exceeding sinfulness, that he has led a worse life than his neighbours. Many excellent persons, whose moral character from boyhood to old age has been free from any stain discernible to their fellow-creatures, have, in their autobiographies and diaries, applied to themselves, and doubtless with sincerity, epithets as severe as could be applied to Titus Oates or Mrs Brownrigg. It is quite certain that Bunyan was, at eighteen, what, in any but the most austerely puritanical circles, would have been considered as a young man of singular gravity and innocence. Indeed, it may be remarked that he, like many other penitents who, in general terms, acknowledge themselves to have been the worst of mankind, fired up, and stood vigorously on his defence, whenever any particular charge was brought against him by others. He declares, it is true, that he had let loose the reins on the neck of his lusts, that he had delighted in all transgressions against the divine law, and that he had been the ringleader of the youth of Elstow in all manner of vice. But when those who wished him ill accused him of licentious amours, he called on God and the angels to attest his purity. No woman, he said, in heaven, earth, or hell, could charge him with having ever made any improper advances to her. Not only had he been strictly faithful to his wife; but he had, even before his marriage, been perfectly spotless. It does not appear from his own confessions, or from the railings of his enemies, that he ever was drunk in his life. One bad habit he contracted, that of using profane language; but he tells us that a single reproof cured him so effectually that he never offended again. The worst that can be laid to the charge of this poor youth, whom it has been the fashion to represent as the most desperate of reprobates, as a village Rochester, is, that he had a great liking for some diversions, quite harmless in themselves, but condemned by the rigid precisians among whom he lived, and for whose opinion he had a great respect. The four chief sins of which he was guilty were dancing, ringing the bells of the parish church, playing at tipcat, and reading the history of Sir Bevis of Southampton. A rector of the school of Laud would have held such a young man up to the whole parish as a model. But Bunyan's notions of good and evil had been learned in a very different school; and he was made miserable by the conflict between his tastes and his scruples.

When he was about seventeen, the ordinary course of his life was interrupted by an event which gave a lasting colour to his thoughts. He enlisted in the Parliamentary army, and served during the decisive campaign of 1645. All that we know of his military career is, that, at the siege of Leicester, one of his comrades, who had

taken his post, was killed by a shot from the town. Bunyan ever after considered himself as having been saved from death by the special interference of Providence. It may be observed that his imagination was strongly impressed by the glimpse which he had caught of the pomp of war. To the last he loved to draw his illustrations of sacred things from camps and fortresses, from guns, drums, trumpets, flags of truce, and regiments arrayed each under its own banner. His Greatheart, his Captain Boanerges, and his Captain Credence are evidently portraits, of which the originals were among those martial saints who fought and expounded in Fairfax's army.

In a few months Bunyan returned home, and married. His wife had some pious relations, and brought him as her only portion some pious books. And now his mind, excitable by nature, very imperfectly disciplined by education, and exposed, without any protection, to the infectious virulence of the enthusiasm which was then epidemic in England, began to be fearfully disordered. In outward things he soon became a strict Pharisee. He was constant in attendance at prayers and sermons. His favourite amusements were, one after another, relinquished, though not without many painful struggles. In the middle of a game at tipcat he paused, and stood staring wildly upwards with his stick in his hand. He had heard a voice asking him whether he would leave his sins and go to heaven, or keep his sins and go to hell; and he had seen an awful countenance frowning on him from the sky. The odious vice of bell-ringing he renounced; but he still for a time ventured to go to the church tower and look on while others pulled the ropes. But soon the thought struck him that, if he persisted in such wickedness, the steeple would fall on his head; and he fled in terror from the accursed place. To give up dancing on the village green was still harder; and some months elapsed before he had the fortitude to part with his darling sin. When this last sacrifice had been made, he was, even when tried by the maxims of that austere time, faultless. All Elstow talked of him as an eminently pious youth. But his own mind was more unquiet than ever. Having nothing more to do in the way of visible reformation, yet finding in religion no pleasures to supply the place of the juvenile amusements which he had relinquished, he began to apprehend that he lay under some special malediction; and he was tormented by a succession of fantasies which seemed likely to drive him to suicide or to Bedlam.

At one time he took it into his head that all persons of Israelite blood would be saved, and tried to make out that he partook of that blood; but his hopes were speedily destroyed by his father, who seems to have had no ambition to be regarded as a Jew.

At another time Bunyan was disturbed by a strange dilemma: "If I have not faith, I am lost; if I have faith, I can work miracles." He was tempted to cry to the puddles between Elstow and Bedford, "Be ye dry," and to stake his eternal hopes on the event.

Then he took up a notion that the day of grace for Bedford and the neighbouring villages was past; that all who were to be saved in that part of England were already converted; and that he had begun to pray and strive some months too late.

Then he was harassed by doubts whether the Turks were not in the right, and the Christians in the wrong. Then he was troubled by a maniacal impulse which prompted him to pray to the trees, to a broomstick, to the parish bull. As yet, however, he was only entering the valley of the shadow of death. Soon the darkness grew thicker. Hideous forms floated before him. Sounds of cursing and wailing were in his ears. His way ran through stench and fire, close to the mouth of the bottomless pit. He began to be haunted by a strange curiosity about the unpardonable sin, and by a morbid longing to commit it. But the most frightful of all the forms which his disease took was a propensity to utter blasphemy, and especially to renounce his share in the benefits of the redemption. Night and day, in bed, at table, at work, evil spirits, as he imagined, were repeating close to his ear the words, "Sell him, sell him." He struck at the hobgoblins; he pushed them from him; but still they were ever at his side. He cried out in answer to them, hour after hour, "Never, never; not for thousands of worlds; not for thousands." At length, worn out by this long agony, he suffered the fatal words to escape him, "Let him go if he will." Then his misery became more fearful than ever. He had done what could not be forgiven. He had forfeited his part of the great sacrifice. Like Esau, he had sold his birthright; and there was no longer any place for repentance. "None," he afterwards wrote, "knows the terrors of those days but myself." He has described his sufferings with singular energy, simplicity, and pathos. He envied the brutes; he envied the very stones on the street, and the tiles on the houses. The sun seemed to withhold its light and warmth from him. His body, though cast in a sturdy mould, and though still in the highest vigour of youth, trembled whole days together with the fear of death and judgment. He fancied that this trembling was the sign set on the worst reprobates, the sign which God had put on Cain. The unhappy man's emotion destroyed his power of digestion. He had such pains that he expected to burst asunder like Judas, whom he regarded as his prototype.

Neither the books which Bunyan read, nor the advisers whom he consulted, were likely to do much good in a case like his. His small library had received a most unseasonable addition, the account of the lamentable end of Francis Spira. One ancient man of high repute for piety, whom the sufferer consulted, gave an opinion which might well have produced fatal consequences. "I am afraid," said Bunyan, "that I have committed the sin against the Holy Ghost." "Indeed," said the old fanatic, "I am afraid that you have."

At length the clouds broke; the light became clearer and clearer; and the enthusiast who had imagined that he was branded with the mark of the first murderer, and destined to the end of the arch-traitor, enjoyed peace and a cheerful confidence in the mercy of God. Years elapsed, however, before his nerves, which had been so perilously overstrained, recovered their tone. When he had joined a Baptist society at Bedford, and was for the first time admitted to partake of the eucharist, it was with difficulty that he could refrain from imprecating destruction on his brethren while the cup was passing from hand to hand. After he had been some time a member of the congregation, he began to preach; and his sermons produced a powerful effect. He was indeed illiterate; but he spoke to illiterate men. The severe training through which he had passed had given him such an experimental knowledge of all the modes of religious melancholy as he could never have gathered from books; and his vigorous genius, animated by a fervent spirit of devotion, enabled him not only to exercise a great influence over the vulgar, but even to extort the half-contemptuous admiration of scholars. Yet it was long before he ceased to be tormented by an impulse which urged him to utter words of horrible impiety in the pulpit.

Counter-irritants are of as great use in moral as in physical diseases. It should seem that Bunyan was finally relieved from the internal sufferings which had embittered his life by sharp persecution from without. He had been five years a preacher, when the Restoration

put it in the power of the Cavalier gentlemen and clergymen all over the country to oppress the dissenters; and, of all the dissenters whose history is known to us, he was perhaps the most hardly treated. In November 1660 he was flung into Bedford jail; and there he remained, with some intervals of partial and precarious liberty, during twelve years. His persecutors tried to extort from him a promise that he would abstain from preaching; but he was convinced that he was divinely set apart and commissioned to be a teacher of righteousness, and he was fully determined to obey God rather than man. He was brought before several tribunals, laughed at, caressed, reviled, menaced, but in vain. He was facetiously told that he was quite right in thinking that he ought not to hide his gift; but that his real gift was skill in repairing old kettles. He was compared to Alexander the coppersmith. He was told that if he would give up preaching he should be instantly liberated. He was warned that if he persisted in disobeying the law he would be liable to banishment, and that if he were found in England after a certain time his neck would be stretched. His answer was, "If you let me out to-day, I will preach again tomorrow." Year after year he lay patiently in a dungeon, compared with which the worst prison now to be found in the island is a palace. His fortitude is the more extraordinary because his domestic feelings were unusually strong. Indeed, he was considered by his stern brethren as somewhat too fond and indulgent a parent. He had several small children, and among them a daughter who was blind, and whom he loved with peculiar tenderness. He could not, he said, bear even to let the wind blow on her; and now she must suffer cold and hunger; she must beg; she must be beaten; "yet," he added, "I must, I must do it." While he lay in prison, he could do nothing in the way of his old trade for the support of his family. He determined, therefore, to take up a new trade. He learned to make long-tagged thread laces; and many thousands of these articles were furnished by him to the hawkers. While his hands were thus busied he had other employments for his mind and his lips. He gave religious instruction to his fellow-captives, and formed from among them a little flock, of which he was himself the pastor. He studied indefatigably the few books which he possessed. His two chief companions were the Bible and Fox's *Book of Martyrs*. His knowledge of the Bible was such that he might have been called a living concordance; and on the margin of his copy of the *Book of Martyrs* are still legible the ill-spelt lines of doggrel in which he expressed his reverence for the brave sufferers, and his implacable enmity to the mystical Babylon.

At length he began to write, and though it was some time before he discovered where his strength lay, his writings were not unsuccessful. They were coarse, indeed, but they showed a keen mother wit, a great command of the homely mother tongue, an intimate knowledge of the English Bible, and a vast and dearly bought spiritual experience. They therefore, when the corrector of the press had improved the syntax and the spelling, were well received by the humbler class of dissenters.

Much of Bunyan's time was spent in controversy. He wrote sharply against the Quakers, whom he seems always to have held in utter abhorrence. It is, however, a remarkable fact that he adopted one of their peculiar fashions; his practice was to write, not November or December, but eleventh month and twelfth month.

He wrote against the liturgy of the Church of England. No two things, according to him, had less affinity than the form of prayer and the spirit of prayer. Those, he said with much point, who have most of the spirit of prayer are all to be found in jail; and those who have most zeal for the form of prayer are all to be found at the alehouse. The doctrinal Articles, on the other hand, he warmly praised, and defended against some Arminian clergymen who had signed them. The most acrimonious of all his works is his answer to Edward Fowler, afterwards bishop of Gloucester, an excellent man, but not free from the taint of Pelagianism.

Bunyan had also a dispute with some of the chiefs of the sect to which he belonged. He doubtless held with perfect sincerity the distinguishing tenet of that sect, but he did not consider that tenet as one of high importance, and willingly joined in communion with pious Presbyterians and Independents. The sterner Baptists, therefore, loudly pronounced him a false brother. A controversy arose which long survived the original combatants. In our own time the cause which Bunyan had defended with rude logic and rhetoric against Kiffin and Danvers was pleaded by Robert Hall with an ingenuity and eloquence such as no polemical writer has ever surpassed.

During the years which immediately followed the Restoration, Bunyan's confinement seems to have been strict. But as the passions of 1660 cooled, as the hatred with which the Puritans had been regarded while their reign was recent gave place to pity, he was less and less harshly treated. The distress of his family, and his own patience, courage, and piety, softened the hearts of his persecutors. Like his own Christian in the cage, he found protectors even among the crowd at Vanity Fair. The bishop of the diocese, Dr Barlow, is said to have interceded for him. At length the prisoner was suffered to pass most of his time beyond the walls of the jail, on condition, as it should seem, that he remained within the town of Bedford.

He owed his complete liberation to one of the worst acts of one of the worst governments that England has ever seen. In 1671 the Cabal was in power. Charles II. had concluded the treaty by which he bound himself to set up the Roman Catholic religion in England. The first step which he took towards that end was to annul, by an unconstitutional exercise of his prerogative, all the penal statutes against the Roman Catholics; and in order to disguise his real design, he annulled at the same time the penal statutes against Protestant Nonconformists. Bunyan was consequently set at large. In the first warmth of his gratitude he published a tract, in which he compared Charles to that humane and generous Persian king, who, though not himself blessed with the light of the true religion, favoured the chosen people, and permitted them, after years of captivity, to rebuild their beloved temple. To candid men, who consider how much Bunyan had suffered, and how little he could guess the secret designs of the court, the unsuspicious thankfulness with which he accepted the precious boon of freedom will not appear to require any apology.

Before he left his prison he had begun the book which has made his name immortal. The history of that book is remarkable. The author was, as he tells us, writing a treatise, in which he had occasion to speak of the stages of the Christian progress. He compared that progress, as many others had compared it, to a pilgrimage. Soon his quick wit discovered innumerable points of similarity which had escaped his predecessors. Images came crowding on his mind faster than he could put them into words, quagmires and pits, steep hills, dark and horrible glens, soft vales, sunny pastures, a gloomy castle, of which the courtyard was strewn with the skulls and bones of murdered prisoners, a town all bustle and splendour, like London on the Lord Mayor's Day, and the narrow path, straight as a

rule could make it, running on up hill and down hill, through city and through wilderness, to the Black River and the Shining Gate. He had found out, as most people would have said, by accident, as he would doubtless have said, by the guidance of Providence, where his powers lay. He had no suspicion, indeed, that he was producing a masterpiece. He could not guess what place his allegory would occupy in English literature; for of English literature he knew nothing. Those who suppose him to have studied the *Faery Queen* might easily be confuted, if this were the proper place for a detailed examination of the passages in which the two allegories have been thought to resemble each other. The only work of fiction, in all probability, with which he could compare his *Pilgrim* was his old favourite, the legend of Sir Bevis of Southampton. He would have thought it a sin to borrow any time from the serious business of his life from his expositions, his controversies, and his lace tags, for the purpose of amusing himself with what he considered merely as a trifle. It was only, he assures us, at spare moments that he returned to the House Beautiful, the Delectable Mountains, and the Enchanted Ground. He had no assistance. Nobody but himself saw a line till the whole was complete. He then consulted his pious friends. Some were pleased. Others were much scandalized. It was a vain story, a mere romance, about giants, and lions, and goblins, and warriors, sometimes fighting with monsters, and sometimes regaled by fair ladies in stately palaces. The loose atheistical wits at Will's might write such stuff to divert the painted Jezebels of the court; but did it become a minister of the gospel to copy the evil fashions of the world? There had been a time when the cant of such fools would have made Bunyan miserable. But that time was past; and his mind was now in a firm and healthy state. He saw that in employing fiction to make truth clear and goodness attractive, he was only following the example which every Christian ought to propose to himself; and he determined to print.

The *Pilgrim's Progress* stole silently into the world. Not a single copy of the first edition is known to be in existence.[1] The year of publication has not been ascertained. It is probable that during some months the little volume circulated only among poor and obscure sectaries. But soon the irresistible charm of a book which gratified the imagination of the reader with all the action and scenery of a fairy tale, which exercised his ingenuity by setting him to discover a multitude of curious analogies, which interested his feelings for human beings, frail like himself, and struggling with temptations from within and from without, which every moment drew a smile from him by some stroke of quaint yet simple pleasantry, and nevertheless left on his mind a sentiment of reverence for God and of sympathy for man, began to produce its effect. In puritanical circles, from which plays and novels were strictly excluded, that effect was such as no work of genius, though it were superior to the *Iliad*, to *Don Quixote*, or to *Othello*, can ever produce on a mind accustomed to indulge in literary luxury. In 1678 came forth a second edition with additions; and then the demand became immense. In the four following years the book was reprinted six times. The eighth edition, which contains the last improvements made by the author, was published in 1682, the ninth in 1684, the tenth in 1685. The help of the engraver had early been called in; and tens of thousands of children looked with terror and delight on execrable copperplates, which represented Christian thrusting his sword into Apollyon, or writhing in the grasp of Giant Despair. In Scotland, and in some of the colonies, the *Pilgrim* was even more popular than in his native country. Bunyan has told us, with very pardonable vanity, that in New England his dream was the daily subject of the conversation of thousands, and was thought worthy to appear in the most superb binding. He had numerous admirers in Holland, and among the Huguenots of France. With the pleasures, however, he experienced some of the pains of eminence. Knavish booksellers put forth volumes of trash under his name, and envious scribblers maintained it to be impossible that the poor ignorant tinker should really be the author of the book which was called his.

He took the best way to confound both those who counterfeited him and those who slandered him. He continued to work the gold-field which he had discovered, and to draw from it new treasures, not indeed with quite such ease and in quite such abundance as when the precious soil was still virgin, but yet with success, which left all competition far behind. In 1684 appeared the second part of the *Pilgrim's Progress*. It was soon followed by the *Holy War*, which if the *Pilgrim's Progress* did not exist, would be the best allegory that ever was written.

Bunyan's place in society was now very different from what it had been. There had been a time when many dissenting ministers, who could talk Latin and read Greek, had affected to treat him with scorn. But his fame and influence now far exceeded theirs. He had so great an authority among the Baptists that he was popularly called Bishop Bunyan. His episcopal visitations were annual. From Bedford he rode every year to London, and preached there to large and attentive congregations. From London he went his circuit through the country, animating the zeal of his brethren, collecting and distributing alms, and making up quarrels. The magistrates seem in general to have given him little trouble. But there is reason to believe that, in the year 1685, he was in some danger of again occupying his old quarters in Bedford jail. In that year the rash and wicked enterprise of Monmouth gave the Government a pretext for prosecuting the nonconformists; and scarcely one eminent divine of the Presbyterian, Independent, or Baptist persuasion remained unmolested. Baxter was in prison: Howe was driven into exile: Henry was arrested. Two eminent Baptists, with whom Bunyan had been engaged in controversy, were in great peril and distress. Danvers was in danger of being hanged; and Kiffin's grandsons were actually hanged. The tradition is that, during those evil days, Bunyan was forced to disguise himself as a waggoner, and that he preached to his congregation at Bedford in a smock-frock, with a cart-whip in his hand. But soon a great change took place. James the Second was at open war with the church, and found it necessary to court the dissenters. Some of the creatures of the Government tried to secure the aid of Bunyan. They probably knew that he had written in praise of the indulgence of 1672, and therefore hoped that he might be equally pleased with the indulgence of 1687. But fifteen years of thought, observation, and commerce with the world had made him wiser. Nor were the cases exactly parallel. Charles was a professed Protestant; James was a professed Papist. The object of Charles's indulgence was disguised; the object of James's indulgence was patent. Bunyan was not deceived. He exhorted his hearers to prepare themselves by fasting and prayer for the danger which menaced their civil and religious liberties, and refused even to speak to the courtier who came down to remodel the corporation of Bedford, and who, as was supposed, had it in charge to offer some municipal dignity to the bishop of the Baptists.

Bunyan did not live to see the Revolution. In the summer of 1688 he undertook to plead the cause of a son

[1] A copy has been discovered in very recent times, and a fac-simile reprint of it was published in 1875.

with an angry father, and at length prevailed on the old man not to disinherit the young one. This good work cost the benevolent intercessor his life. He had to ride through heavy rain. He came drenched to his lodgings on Snow Hill, was seized with a violent fever, and died in a few days (August 31). He was buried in Bunhill Fields; and the spot where he lies is still regarded by the Nonconformists with a feeling which seems scarcely in harmony with the stern spirit of their theology. Many Puritans, to whom the respect paid by Roman Catholics to the reliques and tombs of saints seemed childish or sinful, are said to have begged with their dying breath that their coffins might be placed as near as possible to the coffin of the author of the *Pilgrim's Progress.*

The fame of Bunyan during his life, and during the century which followed his death, was indeed great, but was almost entirely confined to religious families of the middle and lower classes. Very seldom was he during that time mentioned with respect by any writer of great literary eminence. Young coupled his prose with the poetry of the wretched D'Urfey. In the *Spiritual Quixote,* the adventures of Christian are ranked with those of Jack the Giant-Killer and John Hickathrift. Cowper ventured to praise the great allegorist, but did not venture to name him. It is a significant circumstance that, till a recent period, all the numerous editions of the *Pilgrim's Progress* were evidently meant for the cottage and the servant's hall. The paper, the printing, the plates, were all of the meanest description. In general, when the educated minority and the common people differ about the merit of a book, the opinion of the educated minority finally prevails. The *Pilgrim's Progress* is perhaps the only book about which, after the lapse of a hundred years, the educated minority has come over to the opinion of the common people.

The attempts which have been made to improve and to imitate this book are not to be numbered. It has been done into verse; it has been done into modern English. The Pilgrimage of Tender Conscience, the Pilgrimage of Good Intent, the Pilgrimage of Seek Truth, the Pilgrimage of Theophilus, the Infant Pilgrim, the Hindoo Pilgrim, are among the many feeble copies of the great original. But the peculiar glory of Bunyan is that those who most hated his doctrines have tried to borrow the help of his genius. A Catholic version of his parable may be seen with the head of the virgin in the title-page. On the other hand, those Antinomians for whom his Calvinism is not strong enough, may study the Pilgrimage of Hephzibah, in which nothing will be found which can be construed into an admission of free agency and universal redemption. But the most extraordinary of all the acts of Vandalism by which a fine work of art was ever defaced was committed so late as the year 1853. It was determined to transform the *Pilgrim's Progress* into a Tractarian book. The task was not easy; for it was necessary to make two sacraments the most prominent objects in the allegory, and of all Christian theologians, avowed Quakers excepted, Bunyan was the one in whose system the sacraments held the least prominent place. However, the Wicket Gate became a type of Baptism, and the House Beautiful of the Eucharist. The effect of this change is such as assuredly the ingenious person who made it never contemplated. For, as not a single pilgrim passes through the Wicket Gate in infancy, and as Faithful hurries past the House Beautiful without stopping, the lesson which the fable in its altered shape teaches, is that none but adults ought to be baptized, and that the Eucharist may safely be neglected. Nobody would have discovered from the original *Pilgrim's Progress* that the author was not a Pædobaptist. To turn his book into a book against Pædobaptism, was an achievement reserved for an Anglo-Catholic divine. Such blunders must necessarily be committed by every man who mutilates parts of a great work, without taking a comprehensive view of the whole. (M.)

Bunyan's works were first published in a collected form in 1692 (2 vols. folio). Of more recent editions, one of the best is that by George Offor (3 vols. 8vo, 1853). The *Pilgrim's Progress* has probably passed through a larger number of editions than any other book except the Bible. Southey's edition (1830) contains a life of Bunyan, which was afterwards (1839) published separately.

BUNZLAU (1.), the chief town of a circle in the government of Liegnitz in Prussian Silesia, on the right bank of the Bober, about 27 miles from the city of Liegnitz by the Berlin and Breslau Railway, which crosses the river by a noble viaduct. The older part of the town is still surrounded with fortifications. Its public institutions comprise a gymnasium, a normal college, an orphan asylum, and the provincial lunatic asylum. The house is shown where Opitz was born in 1597, and in the market-place is a cast-iron obelisk to field-marshal Kutusoff. The Bunzlau pottery is famous; woollen and linen cloth are manufactured, and there is a considerable trade in grain and cattle. Bunzlau (Boleslavia) received its name in the 12th century from Duke Boleslas, who separated it from the duchy of Glogau. Its importance was increased by numerous privileges and the possession of extensive mining works. It was frequently captured and recaptured in the wars of the 17th century, and in 1739 was completely destroyed by fire. In 1813 it was the scene of a battle between the French and the Allies. Population in 1871, 8812.

BUNZLAU (2.), the chief town of a circle in Bohemia, on the left bank of the Iser, in 50° 25′ N. lat. and 14° 54′ E. long. It has a town-house and castle, supposed to have been built in the 10th century—which is now used as barracks,—a military hospital, a Piaristic college, and a gymnasium. Its manufactures include cotton, woollen, and linen cloth, leather, and soap. Bunzlau is frequently called Jung Bunzlau to distinguish it from Alt Bunzlau, a village on the Elbe. Population (1869), 8695.

BUONAFEDE, Appiano (1716–1793), an Italian writer on philosophy and social economy, was born at Comachio, in Ferrara, in 1716. He became professor of theology at Naples in 1740, and entering the religious body of the Celestines in 1734, rose gradually to be general of the order. He died at Rome in 1793. His principal works, generally published under the assumed title of *Agatopisto Cromaziano,* are on the history of philosophy, *Della Istoria e delle Indole di ogni Filosofia,* 7 vols., 1772, *seq.;* and *Della Restaurazione di ogni Filosofia ne' Secoli* xvi., xvii., xviii., 3 vols., 1789 (which has been translated into German by Heydenreich). The second of these is of great importance for the estimation of the Italian philosophers of the 16th century. His other works are *Istoria critica e filosofica del suicidio,* 1761; *Delle conquiste celebri esaminate col naturale diritto delle genti,* 1763; *Storia critica del moderno diritto di natura e delle genti,* 1789; and a few poems and dramas.

BUONARROTI. See Michel Angelo.

BUOY, a floating body used as a means of denoting any desired spot in a river, channel, or other place frequented by shipping. Buoys are made of various shapes and material, such as a small log of wood 6 or 8 inches diameter and about twice that length, an ordinary cask, or a special structure either of iron or wood, varying in strength, shape, and size according to the duty it is required to perform. Before an anchor is let go, a buoy is generally attached to it, the length of the buoy-rope being slightly greater than the depth of water at high tide. This is done that if for any reason it should become necessary to slip the cable, both anchor and cable may be afterwards recovered

the more readily, their position being denoted by the buoy, and also because it is of service to know the position of the anchor before attempting to weigh it. The buoys most commonly used for this purpose are of the shape of two cones brought together at their bases, and are made of sheet iron, usually galvanized; they are called *Nun-buoys.*

Mooring-buoys are placed in convenient positions so that ships may make fast to them instead of dropping their anchors, and are generally provided with large ring and eye bolts for this purpose. Such buoys are usually of a cylindrical shape, and are made either of iron or wood. They must have sufficient buoyancy to support the weight of a cable of the required strength for the size of ship it is intended to moor, and at the same time be high enough out of the water to make themselves conspicuous. One of the largest and most approved mooring buoys recently made consisted of a cylinder 9 feet long and 6 feet 9 inches diameter, the edges of the ends being rounded off; it was made of iron plates $\frac{3}{8}$ inch thick, and was divided into two water-tight compartments by an iron flat passing through the axis of the cylinder; a watertight iron trunk was fitted, passing through the buoy at the centre, at right angles to the flat, for the cable to go through, so that it might be secured on the upper surface of the buoy.

Buoys are also used to mark the positions of sands and shoals. A usual shape given to them in rivers and sheltered places is that of a frustum of a cone, the smaller end being placed downwards, and the name of the buoy—a name which indicates the shoal it marks—being painted in large letters on the upper end. In more exposed positions the buoys have to be larger and stronger, and are usually made of an egg-shape flattened at the bottom. The largest and most approved are made of iron plates $\frac{1}{2}$ inch and $\frac{3}{8}$ inch thick, with a smaller buoy of similar shape, built within the larger one, so as to divide it into two water-tight compartments. The advantage of the division in this case, and in the case of the mooring buoy described above, is, that the buoy is less liable to be sunk by collision with passing vessels, since if one compartment is damaged the other has sufficient buoyancy to float the whole. The largest of these buoys are about 15 feet 6 inches high, and 10 feet diameter at the widest part, the inner buoy being 9 feet high and 8 feet diameter.

A bell which is frequently placed on a buoy is of great service at night or in foggy weather, the motion of the buoy as it is tossed about by the waves causing the bell to ring.

BUPALUS AND ATHENIS, Greek sculptors, about 540 B.C., lived in the island of Chios, which at that time had a school of sculptors who had acquired some celebrity by their works in marble, which material they had introduced as a substitute for the bronze and wood previously employed for sculpture. Bupalus was the more celebrated of the two brothers. Their father was Archermus, also a sculptor; and it seems from the few notices of their works which exist, that they produced only draped figures, from which it is inferred that their art had not yet advanced to the study of the human figure itself. The Graces, who are now only known as nude figures, were represented as draped by Bupalus for the Temple of Nemesis in Smyrna. He is said also to have made a figure of Tyche (Fortune) for that town. They worked apparently only for the towns in Asia Minor and the Greek islands. Yet Pliny (*Nat. Hist.* xxxvi. 11) says that sculptures from their hands were to be seen in the pediment of the temple of Apollo on the Palatine at Rome, whither they had been brought by Augustus, who seems to have had a taste for early Greek work. But if this is true, and if the figures at all fitted into the peculiar space of a temple pediment, it would follow that they had originally been designed for a similar purpose, and that, therefore, these early artists were able to produce figures for architectural decoration, which hardly seems probable. There is a story that Bupalus had made a caricature portrait of the poet Hipponax, who was known for his ugliness, and that the poet replied by some verses, the sting of which caused the sculptor to hang himself.

BUPHONIA, called also DIIPOLIA, a religious festival held on the 14th of the month Skirophorion (July) at Athens, when the very ancient ceremony was gone through of sacrificing an ox to Zeus, under the following circumstances.—The ox was driven forward to the altar, on which grain was spread, by members of the family of the Kentriadæ, on whom this duty devolved hereditarily (κέντρον, from which the name is derived, means a goad). When it began to eat, one of the family of the Thaulonidæ advanced with an axe, slew the ox, then immediately threw away the axe, and fled. The axe was now carried before the court of the Prytaneum (see AREOPAGUS), and there charged with having caused the death of the ox, for which it was thrown into the sea. Meantime the sacrifice of the ox was accepted in the usual manner.

BURCKHARDT, JOHN LUDWIG (1784–1817), a celebrated Swiss traveller, was born at Kirchgarten, near Lausanne, November 24, 1784. After studying at Leipsic and Göttingen he visited England in the summer of 1806, carrying a letter of introduction from the celebrated Blumenbach to Sir Joseph Banks, who, with the other members of the African Association, accepted his offer to explore the interior of Africa. After studying in London and Cambridge, and inuring himself to all kinds of hardships and privations, he left England in April 1809 for Malta, whence he proceeded, in the following October, to Aleppo. In order that he might acquire Arabic thoroughly he disguised himself as a Mussulman, under the name of Sheik Ibrahim Ibn Abdallah; and, after two years passed in that part of Asia, he had so mastered the language as not to be distinguished from the natives, and had acquired such accurate knowledge of the contents of the Koran, and of the commentaries upon its religion and laws, that after a critical examination the most learned Mussulmans entertained no doubt of his being really what he professed to be, a learned doctor of their law. During his residence in Syria he visited Palmyra, Damascus, Lebanon, and thence repaired to Cairo with the intention of joining a caravan, and travelling to Fezzan, in the north of Africa. In 1812, whilst waiting for the departure of the caravan, he undertook a journey to the Nile, as far up as Mahass; and then, in the character of a poor Syrian merchant, he made a journey through the Nubian desert which Bruce had traversed, passing by Berber and Shendy to Suakin, on the Red Sea, whence he performed the pilgrimage to Mecca by way of Jiddah. After enduring privations and sufferings of the severest kind, he returned to Cairo in a state of great exhaustion; but in the spring of 1816 he travelled to mount Sinai, whence he returned to Cairo in June, and there made preparations for his intended journey to Fezzan, and exploration of the sources of the Niger. Several hindrances prevented his prosecuting this intention, and finally, in April 1817, when the long expected caravan prepared to depart, he was seized with an illness of which he died in October. He had from time to time carefully transmitted to England his journals and remarks, and a very copious series of letters, so that nothing which appeared to him to be interesting in the various journeys he made has been lost. He bequeathed his collection of 800 vols. of Oriental MSS. to the library of Cambridge university.

His works were, *Travels in Nubia*, 1819; *Travels in Syria and the Holy Land*, 1822; *Travels in Arabia*, 1829; *Notes on the Bedouins and Wahabys*, 1830; *Arabic Proverbs*, 1830.

BURDER, GEORGE, one of the founders of the London Missionary Society, was born in London, June 5, 1752,

and died there May 29, 1832. He was pastor of the Independent church at Lancaster from 1778 to 1783. Afterwards, he was for twenty years minister of the West Orchard chapel at Coventry. At the end of this period he removed to London, where for twenty-nine years he officiated at the Fetter Lane chapel. For many years he performed gratuitously the duties of secretary to the London Missionary Society, and edited, with much success, the *Evangelical Magazine*. He is chiefly remembered now as the author of the *Village Sermons*, which appeared at intervals from 1799 to 1812, and were at last completed in six volumes. They have had an extraordinarily wide circulation, and have passed through numerous editions. He edited many works,—among others the *Pilgrim's Progress*, Collings's *Weaver's Pocket-book, or Weaving Spiritualized*, and Henry's *Bible with Improvements*.

BURDETT, Sir Francis (1770–1844), Baronet, was born on the 25th of January 1770. The rudiments of his education he received at Westminster school, whence he removed in due time to Oxford. He did not wait to graduate at that university, but in 1790 set out on a Continental tour, in the course of which he became strongly imbued with the revolutionary principles then dominant in France and other countries. On his return to England in 1793 he married the youngest daughter of Thomas Coutts, a London banker, with whom he received a large fortune. In 1796, through the influence of the duke of Newcastle, he was chosen M.P. for Boroughbridge, on which occasion he had as colleague John Scott, afterwards Lord Eldon. In 1797 he succeeded his grandfather in the baronetcy, his father and elder brother having predeceased him. At the outset of his political career he was a zealous supporter of ultra-liberal measures. In 1802, after a protracted contest, he was elected M.P. for Middlesex, in opposition to the former member, Mr Mainwaring. The election, however, was declared void, and in the subsequent canvass he was defeated. In 1806 he again stood for Middlesex and was again defeated, but when he stood for Westminster in the same year he was elected by a large majority. In March 1810 he wrote a letter to his constituents, denying the right of Government to commit for libel, as they had recently done. This letter was brought under the notice of the House, and the speaker issued a warrant for the committal of Sir Francis to the Tower. The baronet, however, disputed the right of the House, and had to be removed from his own residence by force. There was some collision in consequence between the military and the populace who were devoted to Sir Francis. At the prorogation of parliament he was released, and lost no time in prosecuting the Speaker and the Sergeant-at-arms, but without success. On the occasion of the Manchester riots in 1819 he wrote a letter to his constituents, for which he was tried for libel, found guilty, and condemned to three months' imprisonment, and to pay a fine of £1000. In 1837 he ceased to represent Westminster, and when he was returned for North Wiltshire he joined the Conservative party, which he supported during the remainder of his political career. He died January 23, 1844.

BURG, a town of Prussian Saxony, on the River Ihle, and on the railway from Berlin to Magdeburg, 14 miles N.E. of the latter. It has long been noted for its woollen manufactures, which afford employment to a great part of its population. The town formerly belonged to the Querfurt principality, but was ceded to Brandenburg in 1687. It owes its prosperity to the large influx of industrious French, Palatinate, and Walloon refugees, which took place in the end of the 17th century. Population in 1871, 15,184.

BURGAGE is a form of tenure, both in England and Scotland, applicable to the property connected with the old municipal corporations and their privileges. The term is of less practical importance in the English than in the Scottish system, where it still holds an important place in the practice of conveyancing, real property being there generally divided into feudal-holding and burgage-holding. It is usual to speak of the English burgage-tenure as a relic of Saxon freedom resisting the shock of the Norman conquest and its feudalism, but it is perhaps more correct to consider it a local feature of that general exemption from feudality enjoyed by the *municipia* as a relic of their ancient Roman constitution. The reason for the system preserving its specifically distinct form in Scottish conveyancing is because burgage-holding was an exception to the system of subinfeudation which remained prevalent in Scotland when it was suppressed in England. While other vassals might hold of a graduated hierarchy of overlords up to the crown, the burgess always held directly of the sovereign. It is curious that while in England the burgage-tenure was deemed a species of soccage, to distinguish it from the military holdings, in Scotland it was strictly a military holding, by the service of watching and warding for the defence of the burgh. In England the franchises enjoyed by burgesses, freemen, and other consuetudinary constituencies in burghs, were dependent on the character of the burgage-tenure.

BURGDORF (in French, Berthoud), a town in the Swiss canton of Bern, on the River Emme, about 14 miles by railway from the chief city. It is situated 1840 feet above the level of the sea, and consists of an upper and lower part, which are connected by a spiral arrangement of streets. Its houses are substantially built, and it has an ancient castle, a town-house, a hospital, an orphanage, and a public library. Ribbons and damask, tobacco and chocolate are manufactured; and a large trade is carried on in the dairy produce of the Emmenthal. From the Lueg about $4\frac{1}{2}$ miles to the N.E. a view of the whole Bernese Alps can be obtained. The castle of Burgdorf was built at a very early date, and the town became the capital of Lesser Burgundy and the residence of the dukes of Zähringen. In 1270 they were succeeded by the lords of Kyburg, who, in 1326, pawned their possessions to Ulrich of Signan. In 1384 the town and countship were purchased by Bern for 37,000 florins, and the Bernese magistrates held rule till 1798. Pestalozzi had his educational establishment in the castle for a number of years. Population in 1870, 5078.

BÜRGER, Gottfried August (1748–1794), a celebrated German poet, was born on the 1st of January 1748 at Wolmerswende, a village in the principality of Halberstadt, where his father was Lutheran minister. In his childhood he showed little inclination to study; the Bible was the only book which had any attraction for him, and his first attempts in versification were imitations of the Psalms. It is to this first direction of his studies that we are to attribute the Biblical phrases, and the allusions to Christianity, which we find even in his amatory poetry. He was fond of solitude, and indulged in all the romantic sentiments which deserts and the gloom of forests inspire. From the school of Aschersleben, where his maternal grandfather resided, and which he quitted in consequence of receiving a severe chastisement for composing an epigram, he was sent to the institution at Halle. But at neither of these places did he make much progress, having a taste only for the lessons in prosody and versification. In 1764 Bürger, who was intended for the clerical office, began to attend the course of lectures given by the professors of the university. Klotz, a learned classical scholar, admitted him into the select number of the young men whose talents he took a pleasure in cultivating; but this society appears not to have produced the same favourable effect on the

moral character of Bürger as on his genius. His conduct prejudiced his grandfather Bauer against him; and it was with difficulty that he obtained from him some further assistance, with permission, in the year 1768, to repair to Göttingen to prosecute the study of the law. This change did not make him more regular in his studies; his morals became corrupted; and his grandfather withdrew his protection. Bürger contracted debts; and his situation would have become altogether desperate had not some friends interfered to assist him. An association, memorable in the annals of German literature, and into which Bürger was now admitted, had just been formed at Göttingen; it reckoned among its members Boje, Biester, Sprengel, Hölty, Müller, Voss, the two Counts Stolberg, C. F. Cramer, and Leisewitz. All of these were persons versed in Greek and Roman literature, and at the same time they all idolized Shakespeare. Bürger, in a great measure, owed his style to the enthusiasm which he showed, in common with his literary friends, for our great dramatist. The *Reliques of Ancient English Poetry*, published about this time by Dr Percy, gave an additional impulse to the direction which his mind had taken, and suggested to him some of his most admired productions. Of all his friends, Boje was the one who exercised the greatest influence over him in the choice and treatment of his subjects; and it is to his severe observations that the poetical stanza of Bürger owes a great part of that elegance and roundness which characterize it. To the same friend he was indebted also for some improvement in his circumstances. On the recommendation of Boje he was appointed to the collectorship of Altengleichen, in the principality of Calenberg. The following winter, some fragments of a ghost story, which he heard a peasant girl singing by moonlight, caught his imagination, and suggested his celebrated ballad of *Leonora*. This remarkable production at once established his reputation as a poet. About this time he married a Hanoverian lady, named Leonhart; but this union proved only a source of bitterness, as an unhappy attachment to her younger sister soon after sprung up in his heart. The loss of a sum of money, of which his grandfather had made him a present, was the first commencement of his embarrassments; the taking of a large farm, which he did not know how to manage, increased them. The dismissal from his place, in 1784, in consequence of suspicions (probably ill-founded) raised against the fidelity of his accounts, gave the finishing stroke to his misfortunes. He had a little before lost his wife, whose death was hastened by the culpable passion which Bürger cherished in his heart. Left with two children, and reduced to the inconsiderable emoluments of *The Almanack of the Muses*, which he had edited since 1779, he removed to Göttingen with a view to giving private lessons there, and in the hope of obtaining a professor's chair in the department of belles-lettres. Five years later the title was conferred on him, but without a salary; and this was the only public recompense obtained during his whole life by a man who was one of the favourite authors of his nation, and who, while yet young, had achieved the highest reputation. Scarcely were the ashes of his wife cold when he espoused her sister, whose name his poems have made but too famous. She died in childbed in the beginning of 1786. From that moment his own life only lingered on; and the fire of his genius seemed extinguished with the passion which had so long nourished it. He had scarcely strength enough, in the intervals of his dejection, to finish his *Song of Songs*, a sort of dithyrambic or nuptial hymn, intended to celebrate his second marriage, and which is a strange mixture of frantic passion, religious devotion, and the most bombastic expression. It was the last production of Bürger.

Having studied the philosophy of Kant, he had an idea of deriving some advantage from it at Göttingen, where it had not yet been taught. He undertook to explain it in a course of lectures, which were attended by a great number of students. The satisfaction which the university expressed to him for two cantatas which he composed in 1787, on the occasion of the fifty years' jubilee of this illustrious institution, and his appointment to the situation of professor extraordinary, reanimated his spirits. Fortune appearing to smile on him once more, he formed the design of marrying again. During one of the moments when he was most occupied with this idea he received a letter from Stuttgart, in which a young woman, whose style indicated a cultivated mind, and her sentiments an elevated and feeling heart, after describing to him with enthusiasm the impression which his poetry had made upon her, offered him her hand and heart. The information which he received respecting the character, the fortune, and personal accomplishments of his correspondent having excited his curiosity, he took a journey to Stuttgard, and brought back with him a wife who embittered and dishonoured the rest of his days. In less than three years he saw himself under the necessity of obtaining a divorce from her; and the ruin of his health aggravated the absolute disorder of his finances. Confined to a small chamber, the favourite poet of Germany wasted the remainder of his strength in translations for foreign booksellers; but sickness and grief soon deprived him even of this resource, and he must have died in a state of the most abject poverty if the Government of Hanover had not relieved his necessities. He died June 8, 1794, in the forty-seventh year of his age.

Bürger is only remarkable as a lyric poet; for after having tried all the different species of this class of compositions, he has succeeded eminently only in the song and the ballad. We shall perhaps characterize his genius sufficiently by saying that his imagination is more fresh than rich,—that he has more sensibility than elevation, more naiveté and good nature than delicacy or taste. His style is striking from its clearness and its energy, and an elegance which is rather the result of labour than of natural grace; he possesses, in short, all the qualities which please the multitude. Allowing the title of poet only to those whose writings were calculated to become popular, he early habituated himself to reject whatever appeared to him not sufficiently intelligible and interesting to all classes of readers. He is always clear and forcible; and if at certain times there appears a want of selection and care in the details, yet the sentiments are uniformly noble, and the moral purpose of the majority of his pieces is irreproachable. Of the first three editions of Bürger's works, published at Göttingen, two appeared in 1778 and 1789, in 3 vols. 8vo; and the third, after his death, was published by his friend Ch. Reinhard, in 4 vols., 1796. Later editions of his poems are very numerous.

BURGERSDYK, or BURGERSDICIUS, FRANCIS, a celebrated Dutch logician, was born at Lier, near Delft, in 1590, and died at Leyden in 1629, in the thirty-ninth year of his age. He studied at the university of Leyden, and after completing his academical career there with great distinction, travelled through Germany and France. On arriving at Saumur in the latter country he began to study theology, and was so successful, that, while still a very young man, he was appointed professor of philosophy in that town. This office he held for five years, at the end of which period he returned to Leyden, where he accepted the chair of logic and moral philosophy, and afterwards that of natural philosophy. His *Logic* was at one time widely used, and is still a very valuable compendium. His treatise on ethics, entitled *Idea Philosophiæ Moralis*, was published posthumously in 1644.

BURGESS, DANIEL (1645–1712), a learned and witty dissenting divine of the 17th century, born at Staines,

in Middlesex, of which parish his father was minister. He was educated at Westminster school, and in 1660 was sent to Magdalen Hall, Oxford, but not being able conscientiously to subscribe the necessary formulæ, he quitted that university without taking his degree. In 1667, after taking orders, he was appointed by Lord Orrery to the head-mastership of a school recently established by that nobleman at Charleville in Munster, and soon after he became private chaplain to Lady Mervin, near Dublin. On his return from Ireland he openly avowed his Presbyterian principles, and frequently preached in contempt of the severe laws against nonconformity. For these offences he was imprisoned, but soon regaining his liberty he went to London, where he speedily collected a large congregation, as much by the somewhat fanatical fervour of his piety as by the ludicrous illustrations which he frequently employed in his sermons. Besides preaching, he gave instructions to private pupils, of whom the most distinguished was Henry St John, afterwards Lord Bolingbroke.

BURGESS, THE RIGHT REV. THOMAS (1756–1837), bishop of Salisbury, was born at Odiham, in Hampshire. He was educated at Winchester, and in 1775 he removed to Oxford, where he gained a scholarship at Corpus Christi College. Before graduating, he edited a reprint of Burton's *Pentalogia*. In 1781 he brought out an edition of Dawes's *Miscellanea Critica*, with numerous annotations, a work so favourably received on the Continent that it was reprinted *verbatim* at Leipsic in 1800. In 1783 he became a fellow of his college, and two years later undertook a journey to Holland, where he prosecuted his researches for some time. On his return he was appointed chaplain to Shute Barrington, bishop of Salisbury, through whose influence he obtained a prebendal stall in the cathedral of that town. In 1789 he published his *Considerations on the Abolition of Slavery*, in which he advocated the principle of gradual emancipation. From Salisbury he removed to Durham, where he effected much good among the poorer classes, by publishing and distributing suitable religious works. In 1803 he was promoted by his old schoolfellow Addington, then prime minister, to the vacant see of St David's, which he held for twenty years, and where he gave evidence of his philanthropic disposition by establishing the Society for the Promotion of Christian Knowledge, and founding the College of Lampeter, which he liberally endowed. In 1820 he was appointed first president of the Royal Society of Literature recently founded; and three years later he was promoted to the see of Salisbury, over which he presided for twelve years, prosecuting his benevolent designs with unwearied industry. One of the most important of the many services which he rendered to the church, was the establishment of a Church Union Society for the assistance of infirm and distressed clergymen, to which he bequeathed £3000. In the midst of his useful and laborious career, he was cut off by an attack of dropsy, February 19, 1837. He bequeathed his library and a large sum of money to Lampeter College. A list of his works, which are very numerous, will be found in his biography by J. S. Harford, 2d ed., 1841. In addition to those already referred to may be mentioned his *Essay on the Study of Antiquities, The First Principles of Christian Knowledge; Reflections on the Controversial Writings of Dr Priestley; Emendationes in Suidam et Hesychium et alios Lexicographos Græcos; The Bible, and nothing but the Bible, the Religion of the Church of England.*

BURGHLEY, WILLIAM CECIL, LORD. See CECIL.

BURGKMAIR, HANS or JOHN, a celebrated engraver on wood, believed to have been a pupil of A. Dürer, was born at Augsburg in 1473, and died about 1531. Professor Christ ascribes to him about 700 woodcuts, most of them distinguished by that spirit and freedom which we admire in the works of his supposed master. His principal work is the series of 135 prints representing the triumphs of the Emperor Maximilian I. They are of large size, executed in chiaroscuro, from two blocks, and convey a high idea of his powers. Burgkmair was also an excellent painter in fresco and in distemper, specimens of which are in the galleries of Munich and Vienna, carefully and solidly finished in the style of the old German school. See Kugler's *Handbook of Flemish, Dutch, and German Schools*, by Crowe.

BURGLARY, or NOCTURNAL HOUSE-BREAKING (*burgi latrocinium*), which by the ancient English law was called *hamesucken* (a word also used in the law of Scotland, but in a somewhat different sense), has always been looked upon as a very heinous offence. The definition of a burglar, as given by Sir Edward Coke, is "he that by night breaketh and entereth in a mansion-house with intent to commit a felony." The offence and its punishment are regulated by 24 and 25 Vict. c. 96. Night, for the purposes of that Act (sec. 1), is deemed to commence at nine o'clock in the evening of each day, and to conclude at six o'clock in the morning. Sec. 51 extends the definition of burglary to cases in which a person enters another's dwelling-house with intent to commit felony, or being in such house commits felony therein, and in either case *breaks out* of such dwelling-house by night. The punishment is penal servitude for life, or any term not less than five years, or imprisonment not exceeding two years, with or without hard labour and solitary confinement.

BURGOS, the capital formerly of the kingdom of Old Castile, and now of a separate province, stands on the slope of a hill, the base of which is skirted by the River Arlanzon, 75 miles from Madrid, in lat. 42° 21′ N., long. 3° 43′ W. It is a considerable town, consisting of about 1400 houses, originally girt into the form of a segment of a circle by a wall, some portions of which still remain. On the opposite bank of the river, and connected with the more ancient part of the town by three stone bridges, are the suburbs (Barrio de la Vega), tastefully laid out in pleasure-grounds, while lower down in the midst of the stream is an island furnished with seats and walks as a public promenade. The streets and squares are exceedingly irregular, although spacious and well built. The principal square is the Plaza Mayor, or Plaza de la Constitucion, in the centre of which is a bronze statue of Charles II. The most important public building is the cathedral, begun by Bishop Maurice, traditionally an Englishman, in 1221, but not completed till 1567. It is built in an irregular florid Gothic style, and contains eight chapels, the most famous of which is the Capilla del Condestable, containing the tombs of several of the Velasco family, the hereditary constables of Castile. (See View and Plan in Street's *Gothic Architecture of Spain*, and history by Orcajo, *Historia de la Catedral de Burgos*.) Besides the cathedral there is the Hotel de Ville, or *Casa de Ayuntamiento* (where the bones of the Cid and his wife are preserved in a walnut case), the Palace of Velasco, the church of St Paul, and a beautiful Doric arch, erected in honour of Fernando Gonzalez. There is a fine approach to the city through the massive gate of Santa Maria, surmounted by a statue of the Virgin and Child, and with figures of Fernando Gonzaléz, Charles I., the Cid, and Diego Porcelos in the niches. The hospitals of Burgos are seven in number, and well supported; they are the Hospital San Juan (founded in 1479), the Hospital de la Conception, San Julian, San Quirce, Del Rey, Militar, and the Hospicio y Casa de Epositos. The educational wants of the district are supplied by four primary schools, which are liberally endowed from the municipal funds, and give gratuitous instruction to a considerable number of pupils. There is also a normal school and

a Seminario Conciliar, in which the higher branches are taught. But the most important educational establishment is the Instituto Superior which has a staff of 21 professors, and annually enrols about 250 students. The university, founded in 1550 and restored in 1776, has been long defunct. Burgos is the see of an archbishop, who has for his suffragans the bishops of Pamplona, Palencia, Santander, and Tudela. It has several monasteries, amongst which may be mentioned San Pablo, built about 1415 and now occupied as a store; La Merced, converted into a hospital; the Monasterio de Fredesval, and others. About two miles distant from the town stands the Carthusian convent of Miraflores, built in room of an earlier erection about 1480-7; whilst a little below the promenade of the Isla stands the Santa Maria la Real de las Huelgas, founded by Alphonso VIII., the abbess of which was invested with almost royal prerogatives, and held an unlimited sway over more than fifty villages. Burgos is the official residence of a military staff, and is well provided with barracks and storehouses. The jurisdiction of its courts extends over the whole *audiencia*, including Alava, Guipuzcoa, Logroño, Santander, Soria, and Biscay.

Besides furnishing a mart for the agricultural produce of the neighbouring districts, Burgos carries on a considerable export trade in linen and woollen stuffs, made in imitation of English goods. The principal articles of manufacture are paper, hats, stockings, and leather goods. Its population, which is said at one time to have numbered 80,000, amounted to 25,721 at the census of 1860, which was an increase of 10,931 since 1845.

The history of Burgos cannot be carried back beyond the end of the 9th century. There is no trace of its existence during the occupation of Spain by the Romans. We find the nucleus of it existing in 884, when Diego Porcelos, at the command of Alphonso the Great, built a castle on the right bank of the Arlanzon to check the progress of the Moors. From that time forward it steadily increased in importance, reaching the height of its prosperity in the 15th century, when, alternately with Toledo, it was occupied as a royal residence, but rapidly declining when the court was finally removed to Madrid. Being on one of the principal military roads of the kingdom, it suffered severely during the Peninsular War. In 1808 it was the scene of the defeat of the Spanish army by the French under Marshal Soult. It was unsuccessfully besieged by Wellington in 1812, but was surrendered to him at the opening of the campaign of the following year. (See Waring, *Architectural Studies in Burgos.*)

BURGOYNE, JOHN, an English general in the American War of Independence, was born about 1730, and died in 1792. He is generally supposed to have been a natural son of Lord Bingley, but according to his latest biographer this is not the case. He entered the army when young, and made a runaway marriage with a daughter of the earl of Derby. In 1761 he sat in parliament for Midhurst, and in the following year he served as brigadier-general in Portugal. On the outbreak of the American war he was appointed to a command, and in 1777 he was at the head of the British reinforcements designed for the invasion of the colonies from Canada. In this disastrous expedition he gained possession of Ticonderoga and Fort Edward; but, pushing on, was detached from his communications with Canada, and hemmed in by a superior force at Saratoga. On the 17th October his troops, about 3500 in number, laid down their arms. The success was the greatest the colonists had yet had, and it proved the turning point in the war. The indignation in England against Burgoyne was great, but perhaps unjust. The general himself resigned all his appointments, and demanded a trial, but without avail. In 1782, however, he was restored to his rank, and made commander-in-chief in Ireland. His *Dramatic and Poetical Works* appeared in 2 vols., 1808. One comedy, *The Heiress*, kept the stage for long. (See De Fonblanque, *Political and Military Episodes from the Life and Correspondence of Right Hon. J. Burgoyne*, 1876.)

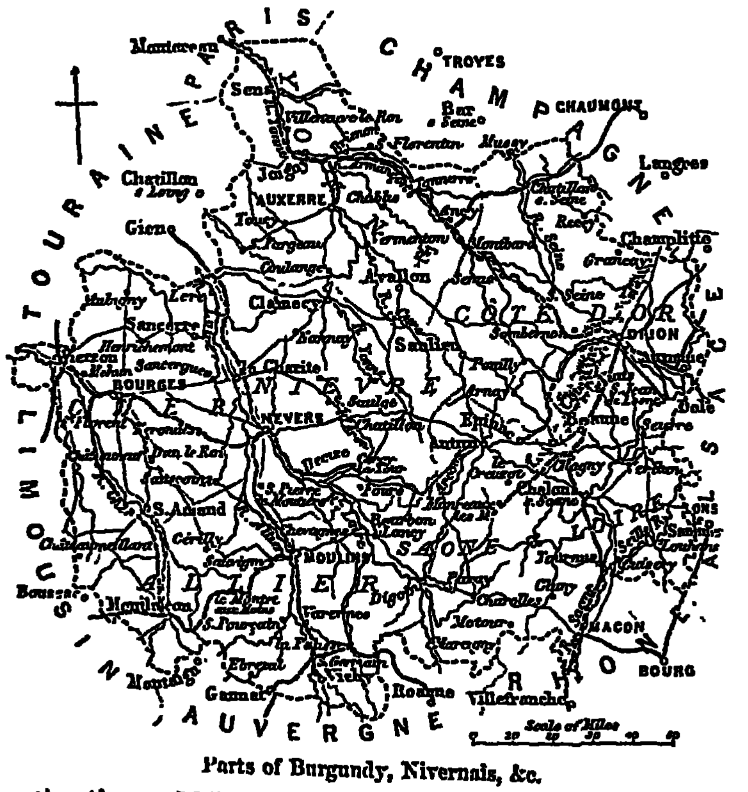
BURGOYNE, SIR JOHN FOX, son of the preceding, was born in 1782, and died October 7, 1871. He was educated at Eton and Woolwich, obtained a commission, and served in 1800 in Abercromby's expedition to the Mediterranean. He afterwards served in the Peninsular campaigns, but before the end of them was sent with Pakenham's division to New Orleans. During the years of peace Burgoyne took an active part in promoting the movement for national defences, and in 1845 was appointed Inspector-General of Fortifications. He was engaged at Alma, Balaklava, and Inkerman, and conducted the siege of Sebastopol till his recall in March 1855. After the conclusion of peace he received a baronetcy, and was made general, and in 1868 was raised to the rank of field-marshal.

BURGUNDIO, an illustrious jurist of the university of Pisa, sometimes erroneously styled Burgundius. He assisted at the Lateran Council in 1179 and died at a very advanced age in 1194. He was a distinguished Greek scholar, and is considered on the authority of Odofredus to have translated into Latin the various Greek fragments which occur in the Pandects, soon after the Pandects were brought to Bologna, with the exception of those in the 27th book, the translation of which has been attributed to Modestinus. The Latin translations which have been ascribed to Burgundio were received at Bologna as an integral part of the text of the Pandects, and form part of that known as *The Vulgate* in distinction from the Florentine text.

BURGUNDY (French, *Bourgogne*) has at various periods been the name of different political and geographical areas. The Burgundians (*Burgundi* or *Burgundiones*) seem to have been a people of German race, who are first found settled between the Oder and the Vistula. At an early period they came into conflict with the Alemanni, whom they defeated; and in the beginning of the 5th century they crossed into Roman Gaul under their leader Gundicar. The Romans not only permitted them to settle within the limits of the empire, but caused the inhabitants of the district to yield up to them one-half of their houses, two-thirds of the cultivated land, and a third of their slaves. The new-comers thus founded, in the country between the Aar and the Rhone, what is usually known as the first kingdom of Burgundy, which lasted till 534, when it was incorporated in the Frankish empire. Gundicar was succeeded in 436 by Gunderic, who somewhat extended his kingdom. In 470 it was parcelled out among his four sons—Chilperic, Gundibald, Godegisil, and Gondemar, who had their headquarters respectively at Geneva, Besançon, Lyons, and Vienne; but it was ultimately reunited in the hands of Gundibald, who is famous for his patronage of the Catholic ecclesiastics and his codification of the Burgundian law, which is consequently known as *Lex Gundibaldia*, or *Loi Gombette*. Gundibald was succeeded in 516 by his son Sigismund, who in turn gave place to Gundimar, the last of the dynasty. On the disintegration of the Carlovingian empire, Boson, the husband of Ermengarde, the daughter of the Emperor Louis II., founded the kingdom of Cisjuran or Lower Burgundy, but in 882 he recognized the overlordship of Charles the Stout. His territory included what was afterwards known as Franche Comté, a part of the later province of Burgundy, Dauphiné, Provence, and part of Languedoc and Savoy. In 888 Boson's example was followed by Rudolph, a Swiss count of Guelf race, who, supported by a large body of civil and ecclesiastical dignitaries called together by him at St Moritz in Valais, established a kingdom known as Transjuran or Upper Burgundy

His son, Rudolph, bartered his rights to the Italian crown for the Cisjuran kingdom, and thus united both Burgundies into what is frequently called the kingdom of Arles, which after various vicissitudes was finally united to the German empire by Conrad II. in 1033.

On the foundation of the Lower Burgundian kingdom by Boson, his brother Richard remained faithful to Charles the Bald of France, and was invested with the duchy of Burgundy, which had been held by various members of the Carlovingian family. King Robert II., however, took possession of it, and bestowed it in 1015 on his son, afterwards Henry I. On the accession of the latter to the throne of France, he gave the duchy to his brother Robert, with whose descendants it continued for a considerable period. In 1361 that elder line of dukes expired, and the duchy was seized by king John, and in 1363 presented by him to his son Philip the Bold as a reward for his bravery at the battle of Poitiers. Thus commenced that famous line of dukes which played so great a part in the history of France during the 14th and 15th centuries, and by the splendour of its achievements and the magnificence of its patronage rivalled the greatest dynasties of



Parts of Burgundy, Nivernais, &c.

the time. Philip's marriage with Margaret of Flanders brought him the countships of Burgundy (Franche Comté), Flanders, Artois, Réthel, and Nevers; and at a later period he purchased the countship of Charolais from the count of Armagnac. He was succeeded in 1404 by John the Fearless (*Jean sans Peur*), who was assassinated at the Bridge of Montereau in 1419, and left the duchy to his son Philip the Good. This duke survived till 1467, and during that time had greatly extended his territory. By very questionable proceedings he obtained possession of Hainault and Holland. Namur was purchased in 1429; and in the following year Brabant and Limburg also fell into his grasp. In 1435 there were further yielded to him, by treaty with France, Macon, Auxerre, Bar-sur-Seine, and various other towns in that district. His son, Charles the Bold, followed in the same course of territorial aggrandizement, and his ambitious projects gradually extended, till he began to aim at the founding of a great Gallo-Belgian kingdom; but his splendid plans came to an untimely end with his own death at the battle of Nancy in 1477, when he was trying to wipe off the disgrace inflicted on his arms by the Swiss at Morat. His daughter and heiress, Mary, married the Archduke Maximilian, son of Frederick III.; and with the exception of the duchy of Burgundy proper, which remained a fief of the French crown, brought with her all the vast inheritance of her father. In 1512 Maximilian incorporated the territory with the German empire under the title of the circle of Burgundy. It was gradually diminished by the encroachments of France, and by the liberation of the Netherlands, so that at the Revolution it only consisted of Brabant, Limburg, Luxembourg, and parts of Flanders, Hainault, Namur, and Guelders.

The duchy meanwhile had been raised with some additions to the rank of a province, and formed a military governorship. It was bounded on the N. by Champagne, E. by Franche Comté and Bresse, S. by Lyonnais and Dauphiné, and W. by Bourbonnais and Nivernais. It was divided into eight districts—Auxerrais, the country of the Mountain, Auxais, Dijonnais, Autunais, Châlonnais, Charolais, and Mâconnais. It possessed a separate assembly of states general, which met every three years at Dijon, the capital, under the presidency most frequently of the governor of the province. The bishop of Autun was at the head of the clergy; the nobility and gentry had a leader of their own election; and the corresponding place in the third estate belonged to the mayor of Dijon.

See Derichsweiler's *Geschichte der Burgunden*, 1863; Barante's *Histoire des ducs de Bourgogne*, 10 vols. 1824; and De Laborde's *Les ducs de Bourgogne*, 1871.

BURHÁNPUR, a town of British India in the Nimár district of the Central Provinces, situated on the north bank of the River Tapti, in 21° 81′ N. lat. and 76° 20′ E. long., at a distance of 280 miles N.E. of Bombay, and 2 miles from the Great Indian Peninsula Railway station of Lálbágh. It was founded in 1400 A.D. by a Mahometan prince of the Farukhí dynasty of Khandesh, whose successors held it for 200 years, when the Farukhí kingdom was annexed to the empire of Akbar. It formed the chief seat of the Government of the Deccan provinces of the Mughul empire till Sháh Jahán removed the capital to Aurangábád, in 1635. Burhánpur was plundered in 1685 by the Marhattás, and repeated battles were fought in its neighbourhood in the struggle betweeen that race and the Musalmáns for the supremacy of India. In 1739 the Mahometans finally yielded to the demand of the Marhattás for a fourth of the revenue, and in 1760 the Nizám of the Deccan ceded Burhánpur to the Peshwá, who in 1778 transferred it to Sindhiá. In the Marhattá war the army under General Wellesley, afterwards the duke of Wellington, took Burhánpur (1803), but the treaty of the following year restored it to Sindhiá. It remained a portion of Sindhiá's dominions till 1860–61, when, in consequence of certain territorial arrangements, the town and surrounding estates were ceded to the British Government. Under the Mughuls the city covered an area of about 5 square miles, and was about 10½ miles in circumference. In the "Ain-i-Akbarí" it is described as a "large city, with many gardens, inhabited by all nations, and abounding with handicraftsmen." Sir Thomas Roe, who visited it in 1614, found that the houses in the town were "only mud cottages, except the prince's house, the chan's, and some few others." In 1865–66 the city contained 8000 houses, with a population of 34,137, which had decreased to 29,303 in 1872. Burhánpur is celebrated for its muslins, flowered silks, and brocades, which, according to Tavernier, who visited it in 1668, were exported in great quantities to Persia, Egypt, Turkey, Russia, and Poland. The gold and silver wires used in the manufacture of these fabrics are drawn with considerable care and skill; and in order to secure the purity of the metals employed for their composition, the wire-drawing under the native rule was done under Government inspection. The town of Burhánpur and its manufactures have

long been on the decline. The buildings of interest in the town are a palace, built by Akbar, called the Lál Kilá or the Red Fort, and the Jumá Masjid built by Aurungzebe. A considerable number of Borás, a class of commercial Mahometans, reside here. Municipal income of the town in 1872, £3514, 10s.; expenditure, £2321, 12s.

BURIAL AND BURIAL ACTS. The practice of burying in churches or churchyards is said to have been connected with the custom of praying for the dead, and it would appear that the earlier practice was burying in the church itself. "In England, about the year 750, spaces of ground adjoining the churches were carefully enclosed and solemnly consecrated and appropriated to the burial of those who had been entitled to attend divine service in those churches, and who now became entitled to render back into those places their remnants to earth, the common mother of mankind, without payment for the ground which they were to occupy, or for the pious offices which solemnized the act of interment" (Lord Stowell). The right to burial in the parish churchyard is far from being merely an ecclesiastical privilege, but at the same time it is intimately bound up with the laws of the Church Establishment. It is a common law right, controlled in many points by the provisions of the law ecclesiastical. This double character is sufficient to explain the controversy which has so long raged round the subject of burials in England. Every man, according to the common law, has a right to be buried in his own churchyard, or, as it is sometimes put, in the churchyard of the parish where he dies. But the churchyard, as well as the church itself, is the freehold of the parson, who can in many respects deal with it as if it were a private estate. A statute of Edward I. (35, st. 2) speaks of the churchyard as the soil of the church, and the trees growing in the churchyard "as amongst the goods of the church, the which laymen have no authority to dispose," and prohibits "the parsons from cutting down such trees unless required for repairs." Notwithstanding the consecration of the church and churchyard, and the fact that they are the parson's freehold, a right of way may be claimed through them by prescription. The right to burial may be subject to the payment of a fee to the incumbent, if such has been the immemorial custom of the parish, but not otherwise. The spirit of the ancient canons regarded such burial fees as of a simoniacal complexion, inasmuch as the consecrated grounds were among the *res sacræ*—a feeling which Lord Stowell says disappeared after the Reformation. No person can be buried in a church without the consent of the incumbent, except when the owner of a manor house prescribes for a burying-place within the church as belonging to the manor house. In the case of Rex *v.* Taylor it was held that an information was grantable against a parson for opposing the burial of a parishioner; but the court would not interpose as to the parson's refusal to read the burial service because he never was baptized—that being matter for the ecclesiastical court. Strangers (or persons not dying in the parish) should not be buried, it appears, without the consent of the parishioners or churchwardens, "whose parochial right of burial is invaded thereby." According to a recent case, a clergyman may be punished for refusing to read the burial service over a person who had ceased to be a parishioner, but was buried in a family vault. While burial is a common-law right, the mode of burial is said to be of ecclesiastical cognizance, and a mandamus to inter a body in an iron coffin was in one case refused. Lord Stowell permitted the use of iron coffins on condition of an increased rate of payment to the parish, observing that the common cemetery is not *res unius ætatis*, the property of one generation now departed, but of the living and of generations yet unborn, and is subject only to temporary appropriation (Gilbert *v.* Buzzard, 2 Consistory Reports, 333). One of the canons of 1603 requires the clergyman under penalty of suspension for three months to bury the corpse without refusal or delay, "unless the party deceased were excommunicated *majori excommunicatione*, for some grievous and notorious crime, and no man able to testify of his repentance." It appears that persons dying in a state of intoxication must be buried with the funeral service of the church. On the other hand no service but that of the Church of England may be used, and no layman or unauthorized person can read or assist in reading a burial service over a dead body in consecrated ground. Nor, it seems, does the church recognize "such an indecency" as burial without service. There are probably many questions as to the common right of burial to which the law has as yet provided no specific answer. In the meantime many attempts have been made to pass a Burials Bill, the main feature of which is the permission to use in churchyards religious services other than that of the Church of England.

The necessity for providing new cemeteries, caused by the natural increase of population, has led to a good deal of legislation, and an Act was passed (10 and 11 Vict. c. 65) to consolidate certain provisions usually contained in Acts authorizing the making of cemeteries. Sec. 23 allows the bishop to consecrate a part of any such cemetery "for the burial of the dead according to the rites of the Established Church." The 15 and 16 Vict. c. 85, for discontinuing burials in the metropolis and opening new burial grounds, was extended to other towns by the 16 and 17 Vict. c. 134. The new burial ground is to be divided into consecrated and unconsecrated portions; and provision is made for building a cemetery chapel for the use of the church, and, if necessary, another for dissenters. By 20 and 21 Vict. c. 81, ground may be consecrated for the burial of poor persons. The same Act allows a burial board to appeal to the archbishop when the ordinary refuses to consecrate a new burial ground, and if after the archbishop confirms the appeal the bishop still refuses to consecrate, the archbishop may licence the grave for interments as if it were consecrated. The 30 and 31 Vict. c. 133 (amended in the following year) provided facilities for cheapening the expense of consecration and for allowing limited owners to convey sites of land for churchyards.

The practice of burying suicides on a public highway, with a stake driven through the body, is prohibited by 4 Geo. IV. c. 52, which requires the coroner to direct their private interment, without religious rites, in the churchyard, within twenty-four hours after the inquest, and between the hours of nine and twelve at night. Bodies may not be removed from burial grounds without licence from a Secretary of State, except when the removal is from one unconsecrated place to another, and is authorized by the ordinary. A coroner may disinter the body in a case of violent death.

In Scotland the obligation of providing and maintaining the churchyard rests on the heritors of the parish. The guardianship of the churchyard belongs to the heritors and also to the kirk-session, either by delegation from the heritors, or in right of its ecclesiastical character. The right of burial appears to be strictly limited to parishioners, although an opinion has been expressed that any person dying in the parish has a right to be buried in the churchyard. The parishioners have no power of management. The presbytery may interfere to compel the heritors to provide due accommodation, but has no further jurisdiction. It is the duty of the heritors to allocate the churchyard. The Scotch law hesitates to attach the ordinary incidents of real property to the churchyard, while English law treats the ground as the parson's freehold. It would be difficult to say who in Scotland is the legal owner of the

soil. Various opinions appear to prevail, *e.g.*, as to grass growing on the surface and minerals found beneath. The difficulty as to religious services does not exist. On the other hand, the religious character of the ground is hostile to many of the legal rights recognized by the English Law.

BURIAL RITES. See FUNERAL.

BURIATS, a Mongolian race, who dwell in the vicinity of the Baikal Lake, for the most part in the government of Irkutsk and the Trans-Baikal territory. They are divided into various tribes or clans, which generally take their names from the locality they frequent. These tribes are subdivided according to kinship. In 1857 the Buriats numbered 190,000, about two-thirds of whom were in the Trans-Baikal territory. They have high cheek-bones, broad and flat noses, and sparse hair on the chin. The men shave their heads like the Chinese, and leave a tail at the top. In summer they dress in silk and cotton gowns, in winter in furs and sheepskins. Their principal occupation is the rearing of cattle; and some of them possess about 500 oxen and nearly 1000 horses. Some tribes, especially the Idinese, the Kudinese, the Alarese, and the Khorinese, also engage in agriculture,—a department of activity which was totally neglected till 1796, when the last-mentioned tribe first turned its attention to it. As early as 1802 the produce of the Irkutsk government was no less than 9800 quarters of grain; and in 1839 the Buriats had 229,500 acres under cultivation. Their soil is generally fertile, and they have an elaborate system of irrigation by canals and trenches. Their only implements are the plough and the harrow. Wheat, rye, spring corn, and oats are their principal crops; and a large quantity of hay is made for their cattle. A good deal of activity is also shown in trapping and fishing. In religion the Buriats are mainly Buddhists; and their head lama (Khambo Lama) lives at the Goose Lake (Gusinoe Ozero). Others are Shamanists, and their most sacred spot is the Shamanic stone at the mouth of the River Angar. A few only, about 9000 or 10,000, are Christians. A knowledge of reading and writing is diffused, especially among the Trans-Baikal Buriats, who possess books of their own, chiefly translated from the Thibetan. Their own language is Mongolian, and presents three distinct dialects, of which the Selengese is nearest to the written form. The Russians became acquainted with the Buriats in the beginning of the 16th century. In 1631 there was built in their territory, for the purpose of bringing them into subjection. the Bratski block-house, whence arose the Russian designation of Bratski applied to the Buriats. This building was followed by the Kanski block-house in 1640, the Verkholenski in 1641, the Udinski in 1648, the Balaganski in 1654, and finally in 1661 by Irkutsk itself. The Buriats frequently besieged these posts and attacked the Russians, and in 1661 they even slew the Russian ambassador, Zabolotski; but in the end of the 17th century they were finally subdued. (See Gmelin, *Siberia*; Pallas, *Mongol. Völkersch.*; Castren, *Versuch einer Burätisch. Sprachlehre.*)

BURIDAN, JEAN, a celebrated philosopher who flourished in the 14th century, was born at Bethune in Artois, but in what year is not known. He studied at Paris under William of Occam, and became an ardent nominalist. The legend which represents him as having been involved, when a student, in the terrible drama of the Tour de Nesle has no discoverable historical basis. He long held the office of professor of philosophy in the university of Paris; in 1327 he was its rector; in 1345 he was deputed to defend its interests before Philip of Valois and at Rome. He was alive in 1358, but the year of his death has not been recorded. The tradition that he was forced to flee from France along with other nominalists, and that he settled in Vienna, and there founded the university in 1356, is unsupported by evidence and in contradiction to the fact that the university of Vienna was founded by Frederick II. in 1237. An ordinance of Louis XI., in 1473, directed against the nominalists, prohibited the reading of his works. These works treat of logic, metaphysics, physics, ethics, and politics; theology is deliberately avoided on the ground that it does not rest on reason alone, and does not proceed exclusively by argumentation. In philosophy Buridan acknowledged no other authority than that of reason. He followed Occam in resolutely denying all objective reality to universals. He held that singulars or individuals alone exist, and that universals are mere words. "Genera et species non sunt nisi termini apud animam existentes vel etiam termini vocales aut scripti, qui non dicuntur genera aut species nisi secundum attributionem ad terminos mentales quos designant." Occam had not gone so far. The chief aim of his logic is commonly represented as having been the devising of rules for the easy and rapid discovery of syllogistic middle terms,—the construction of a dialectical *pons asinorum*,—but there is nothing in his writings to warrant this representation. The parts of logic which he has treated with most minuteness and subtility are the doctrines of modal propositions and of modal syllogisms. In commenting on Aristotle's *Nicomachean Ethics* he dealt in a very independent and interesting manner with the question of free will. The conclusions at which he arrived are remarkably similar to those long afterwards reached by John Locke. The only liberty which he ascribes to the soul is a certain power of suspending the deliberative process and determining the direction of the intellect. Otherwise the will is entirely dependent on the view of the mind, the last result of examination. The comparison of the will unable to act between two equally balanced motives to a hungry ass unable to eat between two equal and equidistant bundles of hay is not found in any of his works, and may have been invented by his opponents to ridicule his determinism. His works are—*Summula de dialectica*, 1487; *Compendium logicæ*, 1489; *Quæstiones in viii. libros physicorum*, &c., 1516; *In Aristotelis Metaphysica*, 1518; *Quæstiones in x. libros ethicorum Aristotelis*, 1489; *Quæstiones in viii. libros politicorum Aristotelis*, 1500. There may be consulted regarding him, besides the general histories of philosophy, Bayle's *Dictionary*, art. "Buridan"; Prantl's *Geschichte der Logik*, bk. iv. 14–38; and Stöckl's *Geschichte der Philosophie des Mittelalters*, Bd. ii. 1023–1028. (R. F.)

BURKE, EDMUND, one of the greatest names in the history of political literature. There have been many more important statesmen, for he was never tried in a position of supreme responsibility. There have been many more effective orators, for lack of imaginative suppleness prevented him from penetrating to the inner mind of his hearers; defects in delivery weakened the intrinsic persuasiveness of his reasoning; and he had not that commanding authority of character and personality which has so often been the secret of triumphant eloquence. There have been many subtler, more original, and more systematic thinkers about the conditions of the social union. But no one that ever lived used the general ideas of the thinker more successfully to judge the particular problems of the statesman. No one has ever come so close to the details of practical politics, and at the same time remembered that these can only be understood and only dealt with by the aid of the broad conceptions of political philosophy. And what is more than all for perpetuity of fame, he was one of the great masters of the high and difficult art of elaborate composition.

A certain doubtfulness hangs over the circumstances of Burke's life previous to the opening of his public career.

The very date of his birth is variously stated, and has given rise to sharper controversy than the small importance of the discrepancies can deserve. The most probable opinion is that he was born at Dublin on the 12th of January 1729, new style. Of his family we know little more than that his father was a Protestant attorney, practising in Dublin, and that his mother was a Catholic, a member of the family of Nagle. He had at least one sister, from whom are descended the only existing representatives of Burke's family; and he had at least two brothers, Garret Burke and Richard Burke, the one older and the other younger than Edmund. The sister, afterwards Mrs French, was brought up and remained throughout life in the religious faith of her mother; Edmund and his brothers followed that of their father. In 1741 the three brothers were sent to school at Ballitore in the county of Kildare. This school was kept by Abraham Shackleton, an Englishman, and a member of the Society of Friends. He appears to have been an excellent teacher and a good and pious man. Burke always looked back on his own connection with the school at Ballitore as among the most fortunate circumstances of his life. Between himself and a son of his instructor there sprang up a close and affectionate friendship, and, unlike so many of the exquisite attachments of youth, this was not choked by the dust of life, nor parted by divergence of pursuit. Richard Shackleton was endowed with a grave, pure, and tranquil nature, constant and austere, yet not without those gentle elements that often redeem the drier qualities of his religious persuasion. When Burke had become one of the most famous men in Europe, no visitor to his house was more welcome than the friend with whom long years before he had tried poetic flights, and exchanged all the sanguine confidences of boyhood. And we are touched to think of the simple-minded guest secretly praying, in the solitude of his room in the fine house at Beaconsfield, that the way of his anxious and overburdened host might be guided by a divine hand.

In 1743 Burke became a student in that famous institution at Dublin which numbers among its sons so many of the shining names of the 18th century in literature, politics, and law. Oliver Goldsmith was at Trinity College at the same time as Burke. But the serious pupil of Abraham Shackleton would not be likely to see much of the wild and squalid sizar. Henry Flood, who was two years younger than Burke, had gone to complete his education at Oxford. Burke, like Goldsmith, achieved no academic distinction. His character was never at any time of the academic cast. The minor accuracies, the limitation of range, the treading and re-treading of the same small patch of ground, the concentration of interest in success before a board of examiners, were all uncongenial to a nature of exuberant intellectual curiosity and of strenuous and self-reliant originality. His knowledge of Greek and Latin was never thorough, nor had he any turn for critical niceties. He could quote Homer and Pindar, and he had read Aristotle. Like others who have gone through the conventional course of instruction, he kept a place in his memory for the various charms of Virgil and Horace, of Tacitus and Ovid; but the master whose page by night and by day he turned with devout hand, was the copious, energetic, flexible, diversified, and brilliant genius of the declamations for Archias the poet and for Milo, against Catiline and against Antony, the author of the disputations at Tusculum and the orations against Verres. Cicero was ever to him the mightiest of the ancient names.* In our own literature Milton seems to have been more familiar to him than Shakespeare, and Spenser was perhaps more of a favourite with him than either.

It is too often the case to be a mere accident that men who become eminent for wide compass of understanding and penetrating comprehension, are in their adolescence unsettled and desultory. Of this Burke is a signal illustration. He left Trinity in 1748, with no great stock of well-ordered knowledge. He neither derived the benefits nor suffered the drawbacks of systematic intellectual discipline. It would seem that in most cases of vigorous and massive faculty, the highest powers are only thoroughly awakened and concentrated by some stimulus that awakens personal and independent activity. Not the advantages of acquisition, but the necessity of production, are with such men the effectual incentive to the exercise of their fullest capacity.

Burke, after taking his degree at Dublin, went in the year 1750 to London to keep terms at the Temple. The ten years that followed were passed in obscure industry. We know hardly any of the details of this period in his life with satisfactory accuracy or on decisive authority. In that respect at least unlike Cicero, Burke was always extremely reserved about his private affairs. It shows a gratuitous meanness of spirit to explain this reserve by supposing that there was something discreditable or sinister to conceal. All that we know of Burke exhibits him as inspired by a resolute pride, a certain stateliness and imperious elevation of mind. Such a character, while free from any weak shame about the shabby necessities of early struggles, yet is naturally unwilling to make them prominent in after life. There is nothing dishonourable in such an inclination. "I was not swaddled and rocked and dandled into a legislator," wrote Burke when very near the end of his days: "*Nitor in adversum* is the motto for a man like me. At every step of my progress in life (for in every step I was traversed and opposed), and at every turnpike I met, I was obliged to show my passport. Otherwise no rank, no toleration even, for me."

All sorts of whispers have been circulated by idle or malicious gossip about Burke's first manhood. He is said to have been one of the too numerous lovers of his fascinating countrywoman, Margaret Woffington. It is hinted that he made a mysterious visit to the American colonies. He was for years accused of having gone over to the Church of Rome, and afterwards recanting. There is not a tittle of positive evidence for these or any of the other statements to Burke's discredit. The common story that he was a candidate for Adam Smith's chair of moral philosophy at Glasgow, when Hume was rejected in favour of an obscure nobody (1751), can be shown to be wholly false. Like a great many other youths with an eminent destiny before them, Burke conceived a strong distaste for the profession of the law. His father, who was an attorney of substance, had a distaste still stronger for so vagrant a profession as letters were in that day. He withdrew the annual allowance, and Burke was launched on the slippery career of the literary and political adventurer. In fairer words, he set to work to win for himself by indefatigable industry and capability in the public interest that position of power or pre-eminence which his detractors acquired either by accident of birth and connections, or else by the vile arts of political intrigue. He began at the bottom of the ladder, mixing with the Bohemian society that haunted the Temple, practising oratory in the free and easy debating societies of Covent Garden and the Strand, and writing for the booksellers.

In 1756 he made his first mark by a satire upon Bolingbroke, entitled *A Vindication of Natural Society*. It purported to be a posthumous work from the pen of Bolingbroke, and to present a view of the miseries and evils arising to mankind from every species of artificial society. The imitation of the fine style of that magnificent writer but bad patriot is admirable. As a satire the piece

is a failure, for the simple reason that the substance of it might well pass for a perfectly true, no less than a very eloquent, statement of social blunders and calamities. Such acute critics as Chesterfield and Warburton thought the performance serious. Rousseau, whose famous discourse on the evils of civilization had appeared six years before, would have read Burke's ironical vindication of natural society without a suspicion of its irony. There have indeed been found persons who insist that the *Vindication* was a really serious expression of the writer's own opinions. This is absolutely incredible, for various reasons. Burke felt now, as he did thirty years later, that civil institutions cannot wisely or safely be measured by the tests of pure reason. His sagacity discerned that the rationalism by which Bolingbroke and the deistic school believed themselves to have overthrown revealed religion, was equally calculated to undermine the structure of political government. This was precisely the actual course on which speculation was entering in France at that moment. His *Vindication* is meant to be a reduction to an absurdity. The rising revolutionary school in France, if they had read it, would have taken it for a demonstration of the theorem to be proved. The only interest of the piece for us lies in the proof which it furnishes, that at the opening of his life Burke had the same scornful antipathy to political rationalism, which flamed out in such overwhelming passion at its close.

In the same year (1756) appeared the *Philosophical Inquiry into the Origin of our Ideas on the Sublime and Beautiful*, a crude and narrow performance in many respects, yet marked by an independent use of the writer's mind, and not without fertile suggestion. It attracted the attention of the rising æsthetic school in Germany. Lessing set about the translation and annotation of it, and Moses Mendelssohn borrowed from Burke's speculation at least one of the most fruitful and important ideas of his own influential theories on the sentiments. In England the *Inquiry* had considerable vogue, but it has left no permanent trace in the development of æsthetic thought in this country.

Burke's literary industry in town was relieved by frequent excursions to the western parts of England, in company with William Burke. There was a lasting intimacy between the two namesakes, and they seem to have been involved together in some important passages of their lives; but we have Edmund Burke's authority for believing that they were probably not kinsmen. The seclusion of these rural sojourns, originally dictated by delicate health, was as wholesome to the mind as to the body. Few men, if any, have ever acquired a settled mental habit of surveying human affairs broadly, of watching the play of passion, interest, circumstance, in all its comprehensiveness, and of applying the instruments of general conceptions and wide principles to its interpretation with respectable constancy, unless they have at some early period of their manhood resolved the greater problems of society in independence and isolation. By 1756 the cast of Burke's opinions was decisively fixed, and they underwent no radical change.

He began a series of *Hints on the Drama*. He wrote a portion of an *Abridgment of the History of England*, and brought it down as far as the reign of John. It included, as was natural enough in a warm admirer of Montesquieu, a fragment on law, of which he justly said that it ought to be the leading science in every well-ordered commonwealth. Burke's early interest in America was shown by an *Account of the European Settlements* on that continent. Such works were evidently a sign that his mind was turning away from abstract speculation to the great political and economic fields, and to the more visible conditions of social stability and the growth of nations. This interest in the concrete phenomena of society inspired him with the idea of the *Annual Register* (1759), which he designed to present a broad grouping of the chief movements of each year. The execution was as excellent as the conception, and if we reflect that it was begun in the midst of that momentous war which raised England to her climax of territorial greatness in East and West, we may easily realize how the task of describing these portentous and far-reaching events would be likely to strengthen Burke's habits of wide and laborious observation, as well as to give him firmness and confidence in the exercise of his own judgment. Dodsley gave him £100 for each annual volume, and the sum was welcome enough, for towards the end of 1756 Burke had married. His wife was the daughter of a Dr Nugent, a physician at Bath. She is always spoken of by his friends as a mild, reasonable, and obliging person, whose amiability and gentle sense did much to soothe the too nervous and excitable temperament of her husband. She had been brought up, there is good reason to believe, as a Catholic, and she was probably a member of that communion at the time of her marriage. Dr Nugent eventually took up his residence with his son-in-law in London, and became a popular member of that famous group of men of letters and artists, whom Boswell has made so familiar and so dear to all later generations. Burke, however, had no intention of being dependent. His consciousness of his own powers animated him with a most justifiable ambition, if ever there was one, to play a part in the conduct of national affairs. Friends shared this ambition on his behalf; one of these was Lord Charlemont. He introduced Burke to William Gerard Hamilton (1759), now only remembered by a nickname derived from the circumstance of his having made a single brilliant speech in the House of Commons, which was followed by years of almost unbroken silence. Hamilton was by no means devoid of sense and acuteness, but in character he was one of the most despicable men then alive. There is not a word too many nor too strong in the description of him by one of Burke's friends, as "a sullen, vain, proud, selfish, cankered-hearted, envious reptile." The reptile's connection, however, was for a time of considerable use to Burke. When he was made Irish Secretary, Burke accompanied him to Dublin, and there learnt Oxenstiern's eternal lesson, that awaits all who penetrate behind the scenes of government, *quam parva sapientia mundus regitur*.

The penal laws against the Catholics, the iniquitous restrictions on Irish trade and industry, the selfish factiousness of the Parliament, the jobbery and corruption of administration, the absenteeism of the landlords, and all the other too familiar elements of that mischievous and fatal system, were then in full force. As was shown afterwards, they made an impresssion upon Burke that was never effaced. So much iniquity and so much disorder may well have struck deep on one whose two chief political sentiments were a passion for order and a passion for justice. He may have anticipated with something of remorse the reflection of a modern historian, that the absenteeism of her landlords has been less of a curse to Ireland than the absenteeism of her men of genius. At least he was never an absentee in heart. He always took the interest of an ardent patriot in his unfortunate country; and, as we shall see, made more than one weighty sacrifice on behalf of the principles which he deemed to be bound up with her welfare.

When Hamilton retired from his post, Burke accompanied him back to London, with a pension of £300 a year on the Irish Establishment. This modest allowance he hardly enjoyed for more than a single year. His patron having discovered the value of so laborious and powerful a subaltern.

wished to bind Burke permanently to his service. Burke declined to sell himself into final bondage of this kind. When Hamilton continued to press his odious pretensions they quarrelled (1765), and Burke threw up his pension. He soon received a more important piece of preferment than any which he could ever have procured through Hamilton.

The accession of George III. to the throne in 1760 had been followed by the disgrace of Pitt, the dismissal of Newcastle, and the rise of Bute. These events marked the resolution of the court to change the political system which had been created by the Revolution of 1688. That system placed the government of the country in the hands of a territorial oligarchy, composed of a few families of large possessions, fairly enlightened principles, and shrewd political sense. It had been preserved by the existence of a Pretender. The two first kings of the House of Hanover could only keep the crown on their own heads by conciliating the Revolution families and accepting Revolution principles. By 1760 all peril to the dynasty was at an end. George III., or those about him, insisted on substituting for the aristocratic division of political power a substantial concentration of it in the hands of the sovereign. The ministers were no longer to be the members of a great party, acting together in pursuance of a common policy accepted by them all as a united body; they were to become nominees of the court, each holding himself answerable not to his colleagues but to the king, separately, individually, and by department. George III. had before his eyes the government of his cousin the great Frederick; but not every one can bend the bow of Ulysses, and, apart from difference of personal capacity and historic tradition, he forgot that a territorial and commercial aristocracy cannot be dealt with in the spirit of the barrack and the drill-ground. But he made the attempt, and resistance to that attempt supplies the key-note to the first twenty-five years of Burke's political life.

Along with the change in system went high-handed and absolutist tendencies in policy. The first stage of the new experiment was very short. Bute, in a panic at the storm of unpopularity that menaced him, resigned in 1763. George Grenville and the less enlightened section of the Whigs took his place. They proceeded to tax the American colonists, to interpose vexatiously against their trade, to threaten the liberty of the subject at home by general warrants, and to stifle the liberty of public discussion by prosecutions of the press. Their arbitrary methods disgusted the nation, and the personal arrogance of the ministers at last disgusted the king. The system received a temporary check. Grenville fell, and the king was forced to deliver himself into the hands of the orthodox section of the Whigs. The Marquis of Rockingham (July 10, 1765) became prime minister, and he was induced to make Burke his private secretary. Before Burke had begun his duties, an incident occurred which illustrates the character of the two men. The old duke of Newcastle, probably desiring a post for some nominee of his own, conveyed to the ear of the new minister various absurd rumours prejudicial to Burke,—that he was an Irish papist, that his real name was O'Bourke, that he had been a Jesuit, that he was an emissary from St Omer's. Lord Rockingham repeated these tales to Burke, who of course denied them with indignation. His chief declared himself satisfied, but Burke, from a feeling that the indispensable confidence between them was impaired, at once expressed a strong desire to resign his post. Lord Rockingham prevailed upon him to reconsider his resolve, and from that day until Lord Rockingham's death in 1782, their relations were those of the closest friendship and confidence.

The first Rockingham administration only lasted a year and a few days, ending in July 1766. The uprightness and good sense of its leaders did not compensate for the weakness of their political connections. They were unable to stand against the coldness of the king, against the hostility of the powerful and selfish faction of Bedford Whigs, and, above all, against the towering predominance of William Pitt. That Pitt did not join them is one of the many fatal miscarriages of history, as it is one of the many serious reproaches to be made against that extraordinary man's chequered and uneven course. An alliance between Pitt and the Rockingham party was the surest guarantee of a wise and liberal policy towards the colonies. He went further than they did, in holding, like Lord Camden, the doctrine that taxation went with representation, and that therefore Parliament had no right to tax the unrepresented colonists. The ministry asserted, what no competent jurist would now think of denying, that Parliament is sovereign; but they went heartily with Pitt in pronouncing the exercise of the right of taxation in the case of the American colonists to be thoroughly impolitic and inexpedient. No practical difference, therefore, existed upon the important question of the hour. But Pitt's prodigious egoism, stimulated by the mischievous counsels of men of the stamp of Lord Shelburne, prevented the fusion of the only two sections of the Whig party that were at once able, enlightened, and disinterested enough to carry on the government efficiently, to check the arbitrary temper of the king, and to command the confidence of the nation. Such an opportunity did not return.

The ministerial policy towards the colonies was defended by Burke with splendid and unanswerable eloquence. He had been returned to the House of Commons for the pocket borough of Wendover, and his first speech (January 27, 1766) was felt to be the rising of a new light. For the space of a quarter of a century, from this time down to 1790, Burke was one of the chief guides and inspirers of a revived Whig party. The "age of small factions" was now succeeded by an age of great principles, and selfish ties of mere families and persons were transformed into a union resting on common conviction and patriotic aims. It was Burke who did more than any one else to give to the Opposition, under the first half of the reign of George III., this stamp of elevation and grandeur. Before leaving office the Rockingham Government repealed the Stamp Act; confirmed the personal liberty of the subject by forcing on the House of Commons one resolution against general warrants, and another against the seizure of papers; and relieved private houses from the intrusion of officers of excise, by repealing the cider tax. Nothing so good was done in an English parliament for nearly twenty years to come. George Grenville, whom the Rockinghams had displaced, and who was bitterly incensed at their formal reversal of his policy, printed a pamphlet to demonstrate his own wisdom and statesmanship. Burke replied in his *Observations on a late Publication on the Present State of the Nation* (1769), in which he showed for the first time that he had not only as much knowledge of commerce and finance, and as firm a hand, in dealing with figures as Grenville himself, but also a broad, general, and luminous way of conceiving and treating politics, in which neither then nor since has he had any rival among English publicists.

It is one of the perplexing points in Burke's private history to know how he lived during these long years of parliamentary opposition. It is certainly not altogether mere impertinence to ask of a public man how he gets what he lives upon, for independence of spirit, which is so hard to the man who lays his head on the debtor's pillow, is the prime virtue in such men. Probity in money is assuredly one of the keys to character, though we must be very careful in ascertaining and proportioning all the circumstances. Now, in 1769, Burke bought an estate at Beaconsfield, in

the county of Buckingham. It was about 600 acres in extent, was worth some £500 a year, and cost £22,000. People have been asking ever since how the penniless man of letters was able to raise so large a sum in the first instance, and how he was able to keep up a respectable establishment afterwards. The suspicions of those who are never sorry to disparage the great have been of various kinds. Burke was a gambler, they hint, in Indian stock, like his kinsmen Richard and William, and like Lord Verney, his political patron at Wendover. Perhaps, again, his activity on behalf of Indian princes, like the Raja of Tanjore, was not disinterested and did not go unrewarded. The answer to all these calumnious inuendoes is to be found in documents and title-deeds of decisive authority, and is simple enough. It is, in short, this. Burke inherited a small property from his elder brother, which he realized. Lord Rockingham advanced him a certain sum (£6000). The remainder, amounting to no less than two-thirds of the purchase-money, was raised on mortgage, and was never paid off during Burke's life. The rest of the story is equally simple, but more painful. Burke made some sort of income out of his 600 acres; he was for a short time agent for New York, with a salary of £700; he continued to work at the *Annual Register* down to 1788. But, when all is told, he never made as much as he spent; and in spite of considerable assistance from Lord Rockingham, amounting it is sometimes said to as much as £30,000, Burke, like the younger Pitt, got every year deeper into debt. Pitt's debts were the result of a wasteful indifference to his private affairs. Burke, on the contrary, was assiduous and orderly, and had none of the vices of profusion. But he had that quality which Aristotle places high among the virtues,—the noble mean of Magnificence, standing midway between the two extremes of vulgar ostentation and narrow pettiness. He was indifferent to luxury, and sought to make life, not commodious nor soft, but high and dignified in a refined way. He loved art, filled his house with statues and pictures, and extended a generous patronage to the painters. He was a collector of books, and, as Crabbe and less conspicuous men discovered, a helpful friend to their writers. Guests were ever welcome at his board; the opulence of his mind and the fervid copiousness of his talk naturally made the guests of such a man very numerous. *Non invideo equidem, miror magis*, was Johnson's good-natured remark, when he was taken over his friend's fine house and pleasant gardens. Johnson was of a very different type. There was something in this external dignity which went with Burke's imperious spirit, his spacious imagination, his turn for all things stately and imposing. We may say, if we please, that Johnson had the far truer and loftier dignity of the two; but we have to take such men as Burke with the defects that belong to their qualities. And there was no corruption in Burke's outlay. When the Pitt administration was formed in 1766, he might have had office, and Lord Rockingham wished him to accept it, but he honourably took his fate with the party. He may have spent £3000 a year, where he would have been more prudent to spend only £2000. But nobody was wronged; his creditors were all paid in time, and his hands were at least clean of traffic in reversions, clerkships, tellerships, and all the rest of the rich sinecures which it was thought no shame in those days for the aristocracy of the land and the robe to wrangle for, and gorge themselves upon, with the fierce voracity of famishing wolves. The most we can say is that Burke, like Pitt, was too deeply absorbed in beneficent service in the affairs of his country, to have for his own affairs the solicitude that would have been prudent.

In the midst of intense political preoccupations, Burke always found time to keep up his intimacy with the brilliant group of his earlier friends. He was one of the commanding figures at the Club at the Turk's Head, with Reynolds and Garrick, Goldsmith and Johnson. The old sage who held that the first Whig was the Devil, was yet compelled to forgive Burke's politics for the sake of his magnificent gifts. "I would not talk to him of the Rockingham party," he used to say, "but I love his knowledge, his genius, his diffusion and affluence of conversation." And everybody knows Johnson's vivid account of him: "Burke, Sir, is such a man that if you met him for the first time in the street, where you were stopped by a drove of oxen, and you and he stepped aside to take shelter but for five minutes, he'd talk to you in such a manner that when you parted you would say, 'This is an extraordinary man.'" They all grieved that public business should draw to party what was meant for mankind. They deplored that the nice and difficult test of answering Berkeley had not been undertaken, as was once intended, by Burke, and sighed to think what an admirable display of subtlety and brilliance such a contention would have afforded them, had not politics "turned him from active philosophy aside." There was no jealousy in this. They did not grudge Burke being the first man in the House of Commons, for they admitted that he would have been the first man anywhere.

With all his hatred for the book-man in politics, Burke owed much of his own distinction to that generous richness and breadth of judgment which had been ripened in him by literature and his practice in it. Like some other men in our history, he showed that books are a better preparation for statesmanship than early training in the subordinate posts and among the permanent officials of a public department. There is no copiousness of literary reference in his work, such as over-abounded in our civil and ecclesiastical publicists of the 17th century. Nor can we truly say that there is much, though there is certainly some, of that tact which literature is alleged to confer on those who approach it in a just spirit and with the true gift. The influence of literature on Burke lay partly in the direction of emancipation from the mechanical formulæ of practical politics; partly, in the association which it engendered, in a powerful understanding like his, between politics and the moral forces of the world, and between political maxims and the old and great sentences of morals; partly in drawing him, even when resting his case on prudence and expediency, to appeal to the widest and highest sympathies; partly, and more than all, in opening his thoughts to the many conditions, possibilities, and "varieties of untried being," in human character and situation, and so giving an incomparable flexibility to his methods of political approach.

This flexibility is not to be found in his manner of composition. That derives its immense power from other sources; from passion, intensity, imagination, size, truth, cogency of logical reason. Those who insist on charm, on winningness in style, on subtle harmonies and fine exquisiteness of suggestion, are disappointed in Burke: they even find him stiff and over-coloured. And there are blemishes of this kind. His banter is nearly always ungainly, his wit blunt, as Johnson said, and often unseasonable. As is usual with a man who has not true humour, Burke is also without true pathos. The thought of wrong or misery moved him less to pity for the victim than to anger against the cause. Again, there are some gratuitous and unredeemed vulgarities; some images that make us shudder. But only a literary fop can be detained by specks like these.

The varieties of Burke's literary or rhetorical method are very striking. It is almost incredible that the superb imaginative amplification of the description of Hyder Ali's descent upon the Carnatic should be from the same pen as

the grave, simple, unadorned *Address to the King* (1777), where each sentence falls on the ear with the accent of some golden-tongued oracle of the wise gods. His stride is the stride of a giant, from the sentimental beauty of the picture of Marie Antoinette at Versailles, or the red horror of the tale of Debi Sing in Rungpore, to the learning, positiveness, and cool judicial mastery of the *Report on the Lords' Journals* (1794), which Philip Francis, no mean judge, declared on the whole to be the "most eminent and extraordinary" of all his productions. But even in the coolest and dryest of his pieces, there is the mark of greatness, of grasp, of comprehension. In all its varieties Burke's style is noble, earnest, deep-flowing, because his sentiment was lofty and fervid, and went with sincerity and ardent disciplined travail of judgment. He had the style of his subjects; the amplitude, the weightiness, the laboriousness, the sense, the high flight, the grandeur, proper to a man dealing with imperial themes, with the fortunes of great societies, with the sacredness of law, the freedom of nations, the justice of rulers. Burke will always be read with delight and edification, because in the midst of discussions on the local and the accidental, he scatters apophthegms that take us into the regions of lasting wisdom. In the midst of the torrent of his most strenuous and passionate deliverances, he suddenly rises aloof from his immediate subject, and in all tranquillity reminds us of some permanent relation of things, some enduring truth of human life or human society. We do not hear the organ tones of Milton, for faith and freedom had other notes in the 18th century. There is none of the complacent and wise-browed sagacity of Bacon, for Burke's were days of personal strife and fire and civil division. We are not exhilarated by the cheerfulness, the polish, the fine manners of Bolingbroke, for Burke had an anxious conscience and was earnest and intent that the good should triumph. And yet Burke is among the greatest of those who have wrought marvels in the prose of our English tongue.

Not all the transactions in which Burke was a combatant could furnish an imperial theme. We need scarcely tell over again the story of Wilkes and the Middlesex election. The Rockingham ministry had been succeeded by a composite Government, of which it was intended that Pitt, now made Lord Chatham and Privy Seal, should be the real chief. Chatham's health and mind fell into disorder almost immediately after the ministry had been formed. The duke of Grafton was its nominal head, but party ties had been broken, the political connections of the ministers were dissolved, and, in truth, the king was now at last a king indeed, who not only reigned but governed. The revival of high doctrines of prerogative in the Crown was accompanied by a revival of high doctrines of privilege in the House of Commons, and the ministry was so smitten with weakness and confusion as to be unable to resist the current of arbitrary policy, and not many of them were even willing to resist it. The unconstitutional prosecution of Wilkes was followed by the fatal recourse to new plans for raising taxes in the American colonies. These two points made the rallying ground of the new Whig opposition. Burke helped to smooth matters for a practical union between the Rockingham party and the powerful triumvirate, composed of Chatham, whose understanding had recovered from its late disorder, and of his brothers-in-law, Lord Temple and George Grenville. He was active in urging petitions from the freeholders of the counties, protesting against the unconstitutional invasion of the right of election. And he added a durable masterpiece to our political literature in a pamphlet which he called *Thoughts on the Cause of the Present Discontents* (1770). The immediate object of this excellent piece was to hold up the court scheme of weak, divided, and dependent administrations in the light of its real purpose and design; to describe the distempers which had been engendered in parliament by the growth of royal influence and the faction of the king's friends; to show that the newly-formed Whig party had combined for truly public ends, and was no mere family knot like the Grenvilles and the Bedfords; and, finally, to press for the hearty concurrence both of public men and of the nation at large in combining against "a faction ruling by the private instructions of a court against the general sense of the people." The pamphlet was disliked by Chatham on the one hand, on no reasonable grounds that we can discover; it was denounced by the extreme popular party of the Bill of Rights, on the other hand, for its moderation and conservatism. In truth, there is as strong a vein of conservative feeling in the pamphlet of 1770 as in the more resplendent pamphlet of 1790. "Our constitution," he said, "stands on a nice equipoise, with steep precipices and deep waters upon all sides of it. In removing it from a dangerous leaning towards one side, there may be a risk of oversetting it on the other. Every project of a material change in a government so complicated as ours is a matter full of difficulties; in which a considerate man will not be too ready to decide, a prudent man too ready to undertake, or an honest man too ready to promise." Neither now nor ever had Burke any other real conception of a polity for England than government by the territorial aristocracy in the interests of the nation at large, and especially in the interests of commerce, to the vital importance of which in our economy he was always keenly and wisely alive. The policy of George III., and the support which it found among men who were weary of Whig factions, disturbed this scheme, and therefore Burke denounced both the court policy and the court party with all his heart and all his strength.

Eloquence and good sense, however, were impotent in the face of such forces as were at this time arrayed against a Government at once strong and liberal. The court was confident that a union between Chatham and the Rockinghams was impossible. The union was in fact hindered by the waywardness and the absurd pretences of Chatham, and the want of force in Lord Rockingham. In the nation at large, the late violent ferment had been followed by as remarkable a deadness and vapidity, and Burke himself had to admit a year or two later that any remarkable robbery at Hounslow Heath would make more conversation than all the disturbances of America. The duke of Grafton went out, and Lord North became the head of a Government, which lasted twelve years (1770–1782), and brought about more than all the disasters that Burke had foretold as the inevitable issue of the royal policy. For the first six years of this lamentable period Burke was actively employed in stimulating, informing, and guiding the patrician chiefs of his party. "Indeed, Burke," said the duke of Richmond, "you have more merit than any man in keeping us together." They were well meaning and patriotic men but it was not always easy to get them to prefer politics to fox-hunting. When he reached his lodgings at night after a day in the city or a skirmish in the House of Commons, Burke used to find a note from the duke of Richmond or the marquis of Rockingham, praying him to draw a protest to be entered on the Journals of the Lords, and in fact he drew all the principal protests of his party between 1767 and 1782. The accession of Charles James Fox to the Whig party, which took place at this time, and was so important an event in its history, was mainly due to the teaching and influence of Burke. In the House of Commons his industry was almost excessive. He was taxed with speaking too often, and with being too forward. And he was mortified by a more serious charge than murmurs about superfluity of zeal. Men said and said again that he was Junius. His very proper unwillingness to stoop to

deny an accusation, that would have been so disgraceful if it had been true, made ill-natured and silly people the more convinced that it was not wholly false. And the preposterous charge has never wholly died out. But whatever the London world may have thought of him, Burke's energy and devotion of character impressed the better minds in the country. In 1774 he received the great distinction of being chosen as one of its representatives by Bristol, then the second town in the kingdom.

In the events which ended in the emancipation of the American colonies from the monarchy, Burke's political genius shone with an effulgence that was worthy of the great affairs over which it shed so magnificent an illumination. His speeches are almost the one monument of the struggle on which a lover of English greatness can look back with pride and a sense of worthiness, such as a churchman feels when he reads Bossuet, or an Anglican when he turns over the pages of Taylor or of Hooker. Burke's attitude in these high transactions is really more impressive than Chatham's, because he was far less theatrical than Chatham; and while he was no less nobly passionate for freedom and justice, in his passion was fused the most strenuous political argumentation and sterling reason of state On the other hand he was wholly free from that quality which he ascribed to Lord George Sackville, a man "apt to take a sort of undecided, equivocal, narrow ground, that evades the substantial merits of the question, and puts the whole upon some temporary, local, accidental, or personal consideration." He rose to the full height of that great argument. Burke here and everywhere else displayed the rare art of filling his subject with generalities, and yet never intruding common-places. No publicist who deals as largely in general propositions has ever been as free from truisms; no one has ever treated great themes with so much elevation, and yet been so wholly secured against the pitfalls of emptiness and the vague. And it is instructive to compare the foundation of all his pleas for the colonists with that on which they erected their own theoretic declaration of independence. The American leaders were impregnated with the metaphysical ideas of rights which had come to them from the rising revolutionary school in France. Burke no more adopted the doctrines of Jefferson in 1776 than he adopted the doctrines of Robespierre in 1793. He says nothing about men being born free and equal, and on the other hand he never denies the position of the court and the country at large, that the home legislature, being sovereign, had the right to tax the colonies. What he does say is that the exercise of such a right was not practicable; that if it were practicable, it was inexpedient; and that, even if this had not been inexpedient, yet, after the colonies had taken to arms, to crush their resistance by military force would not be more disastrous to them than it would be unfortunate for the ancient liberties of Great Britain. Into abstract discussion he would not enter. "Show the thing you contend for to be reason; show it to be common sense; show it to be the means of attaining some useful end." "The question with me is not whether you have a right to render your people miserable, but whether it is not your interest to make them happy." There is no difference in social spirit and doctrine between his protests against the maxims of the English common people as to the colonists and his protests against the maxims of the French common people as to the court and the nobles; and it is impossible to find a single principle either asserted or implied in the speeches on the American revolution which was afterwards repudiated in the writings on the Revolution in France.

It is one of the signs of Burke's singular and varied eminence that hardly any two people agree precisely which of his works to mark as the masterpiece. Every speech or tract that he composed on a great subject becomes, as we read it, the rival of every other. But the *Speech on Conciliation* (1775) has, perhaps, been more universally admired than any of his other productions, partly because its maxims are of a simpler and less disputable kind than those which adorn the pieces on France, and partly because it is most strongly characterized by that deep ethical quality which is the prime secret of Burke's great style and literary mastery. In this speech, moreover, and in the only less powerful one of the preceding year upon American taxation, as well as in the *Letter to the Sheriffs of Bristol* in 1777, we see the all-important truth conspicuously illustrated that half of his eloquence always comes of the thoroughness with which he gets up his case. No eminent man has ever done more than Burke to justify the definition of genius as the consummation of the faculty of taking pains. Labour incessant and intense, if it was not the source, was at least an inseparable condition of his power. And magnificent rhetorician though he was, his labour was given less to his diction than to the facts; his heart was less in the form than the matter. It is true that his manuscripts were blotted and smeared, and that he made so many alterations in the proofs that the printer found it worth while to have the whole set up in type afresh. But there is no polish in his style, as in that of Junius for example, though there is something a thousand times better than polish. "Why will you not allow yourself to be persuaded," said Francis after reading the *Reflections*, "that polish is material to preservation?" Burke always accepted the rebuke, and flung himself into vindication of the sense substance, and veracity of what he had written. His writing is magnificent, because he knew so much, thought so comprehensively, and felt so strongly.

The succession of failures in America, culminating in Cornwallis's surrender at York Town in October 1781, wearied the nation, and at length the persistent and powerful attacks of the opposition began to tell. "At this time," wrote Burke, in words of manly self-assertion, thirteen years afterwards, "having a momentary lead (1780–2), so aided and so encouraged, and as a feeble instrument in a mighty hand,—I do not say I saved my country,—I am sure I did my country important service. There were few indeed at that time that did not acknowledge it. It was but one voice, that no man in the kingdom better deserved an honourable provision should be made for him." In the spring of 1782 Lord North resigned. It seemed as if the court system which Burke had been denouncing for a dozen years was now finally broken, and as if the party which he had been the chief instrument in instructing, directing, and keeping together must now inevitably possess power for many years to come. Yet in a few months the whole fabric had fallen, and the Whigs were thrown into opposition for the rest of the century. The story cannot be omitted in the most summary account of Burke's life. Lord Rockingham came into office on the fall of North. Burke was rewarded for services beyond price by being made Paymaster of the Forces, with the rank of a Privy Councillor. He had lost his seat for Bristol two years before, in consequence of his courageous advocacy of a measure of tolerance for the Catholics, and his still more courageous exposure of the enormities of the commercial policy of England towards Ireland. He sat during the rest of his parliamentary life (to 1794) for Malton, a pocket borough first of Lord Rockingham's, then of Lord Fitzwilliam's. Burke's first tenure of office was very brief. He had brought forward in 1780 a comprehensive scheme of economical reform, with the design of limiting the resources of jobbery and corruption which the Crown was able to use to strengthen its own sinister influence in Parliament. Administrative reform was, next

to peace with the colonies, the part of the scheme of the new ministry to which the king most warmly objected. It was carried out with greater moderation than had been foreshadowed in opposition. But at any rate Burke's own office was not spared. While Charles Fox's father was at the pay-office (1765–1778) he realized as the interest of the cash balances which he was allowed to retain in his hands, nearly a quarter of a million of money. When Burke came to this post the salary was settled at £4000 a year. He did not enjoy the income long. In July 1782 Lord Rockingham died; Lord Shelburne took his place; Fox, who inherited from his father a belief in Lord Shelburne's duplicity, which his own experience of him as a colleague during the last three months had made stronger, declined to serve under him. Burke, though he had not encouraged Fox to take this step, still with his usual loyalty followed him out of office. This may have been a proper thing to do if their distrust of Shelburne was incurable, but the next step, coalition with Lord North against him, was not only a political blunder, but a shock to party morality, which brought speedy retribution. Either they had been wrong, and violently wrong, for a dozen years, or else Lord North was the guiltiest political instrument since Strafford. Burke attempted to defend the alliance on the ground of the substantial agreement between Fox and North in public aims. The defence is wholly untenable. The Rockingham Whigs were as substantially in agreement on public affairs with the Shelburne Whigs as they were with Lord North. The movement was one of the worst in the history of English party. It served its immediate purpose, however, for Lord Shelburne found himself (February 24, 1783) too weak to carry on the government, and was succeeded by the members of the coalition, with the duke of Portland for prime minister (April 2, 1783). Burke went back to his old post at the pay-office and was soon engaged in framing and drawing the famous India Bill. This was long supposed to be the work of Fox, who was politically responsible for it. We may be sure that neither he nor Burke would have devised any government for India which they did not honestly believe to be for the advantage both of that country and of England. But it cannot be disguised that Burke had thoroughly persuaded himself that it was indispensable in the interests of English freedom to strengthen the party hostile to the court. As we have already said, dread of the peril to the constitution from the new aims of George III. was the main inspiration of Burke's political action in home affairs for the best part of his political life. The India Bill strengthened the anti-court party by transferring the government of India to seven persons named in the Bill, and neither appointed nor removable by the Crown. In other words, the Bill gave the government to a board chosen directly by the House of Commons; and it had the incidental advantage of conferring on the ministerial party patronage valued at £300,000 a year, which would remain for a fixed term of years out of reach of the king. In a word, judging the India Bill from a party point of view, we see that Burke was now completing the aim of his project of economic reform. That measure had weakened the influence of the Crown by limiting its patronage. The measure for India weakened the influence of the Crown by giving a mass of patronage to the party which the king hated. But this was not to be. The India Bill was thrown out by means of a royal intrigue in the Lords, and the ministers were instantly dismissed (December 18, 1783). Young William Pitt, then only in his twenty-fifth year, had been Chancellor of the Exchequer in Lord Shelburne's short ministry, and had refused to enter the coalition Government from an honourable repugnance to join Lord North. He was now made prime minister. The country in the election of the next year ratified the king's judgment against the Portland combination; and the hopes which Burke had cherished for a political life-time were irretrievably ruined.

The six years that followed the great rout of the orthodox Whigs were years of repose for the country, but it was now that Burke engaged in the most laborious and formidable enterprize of his life, the impeachment of Warren Hastings for high crimes and misdemeanours in his government of India. His interest in that country was of old date. It arose partly from the fact of William Burke's residence there, partly from his friendship with Philip Francis, but most of all, we suspect, from the effect which he observed Indian influence to have in demoralizing the House of Commons. "Take my advice for once in your life," Francis wrote to Shee; "lay aside 40,000 rupees for a seat in Parliament: in this country that alone makes all the difference between somebody and nobody." The relations, moreover, between the East India Company and the Government were of the most important kind, and occupied Burke's closest attention from the beginning of the American war down to his own India Bill and that of Pitt and Dundas. In February 1785 he delivered one of the most famous of all his speeches, that on the nabob of Arcot's debts. The real point of this superb declamation was Burke's conviction that ministers supported the claims of the fraudulent creditors in order to secure the corrupt advantages of a sinister parliamentary interest. His proceedings against Hastings had a deeper spring. The story of Hastings's crimes, as Macaulay says, made the blood of Burke boil in his veins. He had a native abhorrence of cruelty, of injustice, of disorder, of oppression, of tyranny, and all these things in all their degrees marked Hastings's course in India. They were, moreover, concentrated in individual cases, which exercised Burke's passionate imagination to its profoundest depths, and raised it to such a glow of fiery intensity as has never been rivalled in our history. For it endured for fourteen years, and was just as burning and as terrible when Hastings was acquitted in 1795, as in the Select Committee of 1781 when Hastings's enormities were first revealed. "If I were to call for a reward," wrote Burke, "it would be for the services in which for fourteen years, without intermission, I showed the most industry and had the least success, I mean in the affairs of India; they are those on which I value myself the most; most for the importance; most for the labour; most for the judgment; most for constancy and perseverance in the pursuit." Sheridan's speech in the House of Commons upon the charge relative to the Begums of Oude probably excelled anything that Burke achieved, as a dazzling performance abounding in the most surprising literary and rhetorical effects. But neither Sheridan nor Fox was capable of that sustained and overflowing indignation at outraged justice and oppressed humanity, that consuming moral fire, which burst forth again and again from the chief manager of the impeachment, with such scorching might as drove even the cool and intrepid Hastings beyond all self-control, and made him cry out with protests and exclamations like a criminal writhing under the scourge. Burke, no doubt, in the course of that unparalleled trial showed some prejudice; made some minor overstatements of his case; used many intemperances; and suffered himself to be provoked into expressions of heat and impatience by the cabals of the defendant and his party, and the intolerable incompetence of the tribunal. It is one of the inscrutable perplexities of human affairs, that in the logic of practical life, in order to reach conclusions that cover enough for truth, we are constantly driven to premises that cover too much, and that in order to secure their right weight to justice and reason, good men are forced to fling the two-edged sword of passion into the same scale. But these excuses were

mere trifles, and well deserve to be forgiven, when we think that though the offender was in form acquitted, yet Burke succeeded in these fourteen years of laborious effort in laying the foundations once for all of a moral, just, philanthropic, and responsible public opinion in England with reference to India, and in doing so performed perhaps the *most* magnificent service that any statesman has ever had it in his power to render to humanity.

Burke's first decisive step against Hastings was a motion for papers in the spring of 1786; the thanks of the House of Commons to the managers of the impeachment were voted in the summer of 1794. But in those eight years some of the most astonishing events in history had changed the political face of Europe. Burke was more than sixty years old when the states-general met at Versailles in the spring of 1789. He had taken a prominent part on the side of freedom in the revolution which stripped England of her empire in the West. He had taken a prominent part on the side of justice, humanity, and order, in dealing with the revolution which had brought to England new empire in the East. The same vehement passion for freedom, justice, humanity, and order was roused in him at a very early stage of the third great revolution in his history—the revolution which overthrew the old monarchy in France. From the first Burke looked on the events of 1789 with doubt and misgiving. He had been in France in 1773, where he had not only the famous vision of Marie Antoinette at Versailles, "glittering like the morning star, full of life, and splendour, and joy," but had also supped and discussed with some of the destroyers, the encyclopædists, "the sophisters, economists, and calculators." His first speech on his return to England was a warning (March 17, 1773) that the props of good government were beginning to fail under the systematic attacks of unbelievers, and that principles were being propagated that would not leave to civil society any stability. The apprehension never died out in his mind; and when he knew that the principles and abstractions, the un-English dialect and destructive dialectic, of his former acquaintances were predominant in the National Assembly, his suspicion that the movement would end in disastrous miscarriage waxed into certainty.

The scene grew still more sinister in his eyes after the march of the mob from Paris to Versailles in October, and the violent transport of the king and queen from Versailles to Paris. The same hatred of lawlessness and violence which fired him with a divine rage against the Indian malefactors was aroused by the violence and lawlessness of the Parisian insurgents. The same disgust for abstractions and naked doctrines of right that had stirred him against the pretensions of the British Parliament in 1774 and 1776, was revived in as lively a degree by political conceptions which he judged to be identical in the French Assembly of 1789. And this anger and disgust were exasperated by the dread with which certain proceedings in England had inspired him, that the aims, principles, methods, and language which he so misdoubted or abhorred in France were likely to infect the people of Great Britain.

In November 1790 the town, which had long been eagerly expecting a manifesto from Burke's pen, was electrified by the *Reflections on the Revolution in France, and on the proceedings in certain societies in London relative to that event*. The generous Windham made an entry in his diary of his reception of the new book. "What shall be said," he added, "of the state of things, when it is remembered that the writer is a man decried, persecuted, and proscribed; not being much valued even by his own party, and by half the nation considered as little better than an ingenious madman?" But the writer now ceased to be decried, persecuted, and proscribed, and his book was seized as the expression of that new current of opinion in Europe which the more recent events of the Revolution had slowly set flowing. Its vogue was instant and enormous. Eleven editions were exhausted in little more than a year, and there is probably not much exaggeration in the estimate that 30,000 copies were sold before Burke's death seven years afterwards. George III. was extravagantly delighted; Stanislaus of Poland sent Burke words of thanks and high glorification and a gold medal. Catherine of Russia, the friend of Voltaire and the benefactress of Diderot, sent her congratulations to the man who denounced French philosophers as miscreants and wretches. "One wonders," Romilly said by-and-by, "that Burke is not ashamed at such success." Mackintosh replied to him temperately in the *Vindiciæ Gallicæ*, and Tom Paine replied to him less temperately but far more trenchantly and more shrewdly in the *Rights of Man*. Arthur Young, with whom he had corresponded years before on the mysteries of deep ploughing and fattening hogs, added a cogent polemical chapter to that ever admirable work, in which he showed that he knew as much more than Burke about the old system of France as he knew more than Burke about soils and roots. Philip Francis, to whom he had shown the proof-sheets, had tried to dissuade Burke from publishing his performance. The passage about Marie Antoinette, which has since become a stock piece in books of recitation, seemed to Francis a mere piece of foppery; for was she not a Messalina and a jade? "I know nothing of your story of Messalina," answered Burke; "am I obliged to prove judicially the virtues of all those I shall see suffering every kind of wrong and contumely and risk of life, before I endeavour to interest others in their sufferings? . . . Are not high rank, great splendour of descent, great personal elegance, and outward accomplishments, ingredients of moment in forming the interest we take in the misfortunes of men? . . . I tell you again that the recollection of the manner in which I saw the queen of France in 1774, and the contrast between that brilliancy, splendour, and beauty, with the prostrate homage of a nation to her, and the abominable scene of 1789 which I was describing, *did* draw tears from me and wetted my paper. These tears came again into my eyes almost as often as I looked at the description,—they may again. You do not believe this fact, nor that these are my real feelings; but that the whole is affected, or as you express it, downright foppery. My friend, I tell you it is truth; and that it is true and will be truth when you and I are no more; and will exist as long as men with their natural feelings shall exist" (*Corr.* iii. 139).

Burke's conservatism was, as such a passage as this may illustrate, the result partly of strong imaginative associations clustering round the more imposing symbols of social continuity, partly of a sort of corresponding conviction in his reason that there are certain permanent elements of human nature out of which the European order had risen and which that order satisfied, and of whose immense merits, as of its mighty strength, the revolutionary party in France were most fatally ignorant. When Romilly saw Diderot in 1783, the great encyclopædic chief assured him that submission to kings and belief in God would be at an end all over the world in a very few years. When Condorcet described the Tenth Epoch in the long development of human progress, he was sure not only that fulness of light and perfection of happiness would come to the sons of men, but that they were coming with all speed. Only those who know the incredible rashness of the revolutionary doctrine in the mouths of its most powerful professors at that time; only those who know their absorption in ends and their inconsiderateness about means, can feel how profoundly right Burke was in all this part of his contention. Napoleon, who had begun life as a disciple of Rousseau, confirmed the wisdom of the philosophy of

Burke when he came to make the Concordat That measure was in one sense the outcome of a mere sinister expediency, but that such a measure was expedient at all sufficed to prove that Burke's view of the present possibilities of social change was right, and the view of the Rousseauites and too sanguine Perfectibilitarians wrong. As we have seen, Burke's very first piece, the satire on Bolingbroke, sprang from his conviction that merely rationalistic or destructive criticism, applied to the vast complexities of man in the social union, is either mischievous or futile, and mischievous exactly in proportion as it is not futile.

To discuss Burke's writings on the Revolution would be to write first a volume upon the abstract theory of society, and then a second volume on the history of France. But we may make one or two further remarks. One of the most common charges against Burke was that he allowed his imagination and pity to be touched only by the sorrows of kings and queens, and forgot the thousands of oppressed and famine-stricken toilers of the land. "No tears are shed for nations," cried Francis, whose sympathy for the Revolution was as passionate as Burke's execration of it. "When the provinces are scourged to the bone by a mercenary and merciless military power, and every drop of its blood and substance extorted from it by the edicts of a royal council, the case seems very tolerable to those who are not involved in it. When thousands after thousands are dragooned out of their country for the sake of their religion, or sent to row in the galleys for selling salt against law,—when the liberty of every individual is at the mercy of every prostitute, pimp, or parasite that has access to power or any of its basest substitutes,—my mind, I own, is not at once prepared to be satisfied with gentle palliatives for such disorders" (*Francis to Burke*, November 3, 1790). This is a very terse way of putting a crucial objection to Burke's whole view of French affairs in 1789. His answer was tolerably simple. The Revolution, though it had made an end of the Bastille, did not bring the only real practical liberty, that is to say, the liberty which comes with settled courts of justice, administering settled laws, undisturbed by popular fury, independent of everything but law, and with a clear law for their direction. The people, he contended, were no worse off under the old monarchy than they will be in the long run under assemblies that are bound by the necessity of feeding one part of the community at the grievous charge of other parts, as necessitous as those who are so fed; that are obliged to flatter those who have their lives at their disposal by tolerating acts of doubtful influence on commerce and agriculture, and for the sake of precarious relief to sow the seeds of lasting want; that will be driven to be the instruments of the violence of others from a sense of their own weakness, and, by want of authority to assess equal and proportioned charges upon all, will be compelled to lay a strong hand upon the possessions of a part. As against the moderate section of the Constituent Assembly this was just.

One secret of Burke's views of the Revolution was the contempt which he had conceived for the popular leaders in the earlier stages of the movement. In spite of much excellence of intention, much heroism, much energy, it is hardly to be denied that the leaders whom that movement brought to the surface were almost without exception men of the poorest political capacity. Danton, no doubt, was abler than most of the others, yet the timidity or temerity with which he allowed himself to be vanquished by Robespierre showed that even he was not a man of commanding quality. The spectacle of men so rash, and so incapable of controlling the forces which they seemed to have presumptuously summoned, excited in Burke both indignation and contempt. And the leaders of the Constituent who came first on the stage, and hoped to make a revolution with rose-water, and hardly realized any more than Burke did how rotten was the structure which they had undertaken to build up, almost deserved his contempt, even if, as is certainly true, they did not deserve his indignation. It was only by revolutionary methods, which are in their essence and for a time as arbitrary as despotic methods, that the knot could be cut. Burke's vital error was his inability to see that a root and branch revolution was, under the conditions, inevitable. His cardinal position, from which he deduced so many important conclusions, namely, that the parts and organs of the old constitution of France were sound, and only needed moderate invigoration, is absolutely mistaken and untenable. There was not a single chamber in the old fabric that was not crumbling and tottering. The court was frivolous, vacillating, stone deaf and stone blind; the gentry were amiable, but distinctly bent to the very last on holding to their privileges, and they were wholly devoid both of the political experience that only comes of practical responsibility for public affairs, and of the political sagacity that only comes of political experience. The parliaments or tribunals were nests of faction and of the deepest social incompetence. The very sword of the state broke short in the king's hand. If the king or queen could either have had the political genius of Frederick the Great, or could have had the good fortune to find a minister with that genius, and the good sense and good faith to trust and stand by him against mobs of aristocrats and mobs of democrats; if the army had been sound and the states-general had been convoked at Bourges or Tours instead of at Paris, then the type of French monarchy and French society might have been modernized without convulsion. But none of these conditions existed.

When he dealt with the affairs of India, Burke passed over the circumstances of our acquisition of power in that continent. "There is a sacred veil to be drawn over the beginnings of all government," he said. "The first step to empire is revolution, by which power is conferred; the next is good laws, good order, good institutions, to give that power stability." Exactly on this broad principle of political force, revolution was the first step to the assumption by the people of France of their own government. Granted that the Revolution was inevitable and indispensable, how was the nation to make the best of it? And how were surrounding nations to make the best of it? This was the true point of view. But Burke never placed himself at such a point. He never conceded the postulate, because, though he knew France better than any body in England except Arthur Young, he did not know her condition well enough. "Alas!" he said, "they little know how many a weary step is to be taken before they can form themselves into a mass which has a true, political personality." And how true this was, it will perhaps take more than a century fully to show. But then nations like individual men are often driven to travel over a weary road that has been long prepared for them by the far-reaching errors of their forefathers and it was only by the journey of which he wisely forewarned them, that they could hope to arrive at the goal of which he unwisely despaired for them.

Burke's view of French affairs, however consistent with all his former political conceptions, put an end to more than one of his old political friendships. He had never been popular in the House of Commons, and the vehemence, sometimes amounting to fury, which he had shown in the debates on the India Bill, on the regency, on the impeachment of Hastings, had made him unpopular even among men on his own side. In May 1789—that memorable month of May in which the states-general marched in

impressive array to hear a sermon at the church of Nôtre Dame at Versailles—a vote of censure had actually been passed on him in the House of Commons for a too severe expression used against Hastings. Fox, who led the party, and Sheridan, who led Fox, were the intimates of the Prince of Wales; and Burke would have been as much out of place in that circle of gamblers and profligates as Milton would have been out of place in the court of the Restoration. The prince, as somebody said, was like his father in having closets within cabinets and cupboards within closets. When the debates on the regency were at their height we have Burke's word that he was not admitted to the private counsels of the party. Though Fox and he were on friendly terms in society, yet Burke admits that for a considerable period before 1790 there had been between them "distance, coolness, and want of confidence, if not total alienation on his part." The younger Whigs had begun to press for shorter parliaments, for the ballot, for redistribution of political power. Burke had never looked with any favour on these projects. His experience of the sentiment of the populace in the two greatest concerns of his life,—American affairs and Indian affairs,—had not been likely to prepossess him in favour of the popular voice as the voice of superior political wisdom. He did not absolutely object to some remedy in the state of representation (*Corr.* ii. 387), still he vigorously resisted such proposals as the duke of Richmond's in 1780 for manhood suffrage. The general ground was this:—"The machine itself is well enough to answer any good purpose, provided the materials were sound. But what signifies the arrangement of rottenness?"

Bad as the parliaments of George III. were, they contained their full share of eminent and capable men; and, what is more, their very defects were the exact counterparts of what we now look back upon as the prevailing stupidity in the country. What Burke valued was good government. His *Report on the Causes of the Duration of Mr Hastings's Trial* shows how wise and sound were his views of law reform. His *Thoughts on Scarcity* attest his enlightenment on the cardinal necessities of trade and manufacture, and even furnished arguments to Cobden fifty years afterwards. Parliaments were competent to discuss, and willing to pass, all measures for which the average political intelligence of the country was ripe. Burke did not believe that altered machinery was at that time needed to improve the quality of legislation. If wiser legislation followed the great reform of 1832, Burke would have said this was because the political intelligence of the country had improved.

Though averse at all times to taking up parliamentary reform, he thought all such projects downright crimes in the agitation of 1791–2. This was the view taken by Burke, but it was not the view of Fox, nor of Sheridan, nor of Francis, nor of many others of his party, and difference of opinion here was naturally followed by difference of opinion upon affairs in France. Fox, Grey, Windham, Sheridan, Francis, Lord Fitzwilliam, and most of the other Whig leaders, welcomed the Revolution in France. And so did Pitt, too, for some time. "How much the greatest event it is that ever happened in the world," cried Fox, with the exaggeration of a man ready to dance the carmagnole, "and how much the best!" The dissension between a man who felt so passionately as Burke, and a man who spoke so impulsively as Charles Fox, lay in the very nature of things. Between Sheridan and Burke there was an open breach in the House of Commons upon the Revolution so early as February 1790, and Sheridan's influence with Fox was strong. This divergence of opinion destroyed all the elation that Burke might well have felt at his compliments from kings, his gold medals, his twelve editions. But he was too fiercely in earnest in his horror of Jacobinism to allow mere party associations to guide him. In May 1791 the thundercloud burst, and a public rupture between Burke and Fox took place in the House of Commons.

The scene is famous in our parliamentary annals. The minister had introduced a measure for the division of the province of Canada and for the establishment of a local legislature in each division. Fox in the course of debate went out of his way to laud the Revolution, and to sneer at some of the most effective passages in the *Reflections*. Burke was not present, but he announced his determination to reply. On the day when the Quebec Bill was to come on again, Fox called upon Burke, and the pair walked together from Burke's house in Duke Street down to Westminster. The Quebec Bill was recommitted, and Burke at once rose and soon began to talk his usual language against the Revolution, the rights of man, and Jacobinism whether English and French. There was a call to order. Fox, who was as sharp and intolerant in the House as he was amiable out of it, interposed with some words of contemptuous irony. Pitt, Grey, Lord Sheffield, all plunged into confused and angry debate, as to whether the French Revolution was a good thing, and whether the French Revolution, good or bad, had anything to do with the Quebec Bill. At length Fox, in seconding a motion for confining the debate to its proper subject, burst into the fatal question beyond the subject, taxing Burke with inconsistency, and taunting him with having forgotten that ever-admirable saying of his own about the insurgent colonists, that he did not know how to draw an indictment against a whole nation. Burke replied in tones of firm self-repression; complained of the attack that had been made upon him; reviewed Fox's charges of inconsistency; enumerated the points on which they had disagreed, and remarked that such disagreements had never broken their friendship. But whatever the risk of enmity, and however bitter the loss of friendship, he would never cease from the warning to flee from the French constitution. "But there is no loss of friends," said Fox in an eager under tone. "Yes," cried Burke, "there *is* a loss of friends. I know the penalty of my conduct. I have done my duty at the price of my friend—our friendship is at an end." Fox rose, but was so overcome that for some moments he could not speak. At length, his eyes streaming with tears, and in a broken voice, he deplored the breach of a twenty years' friendship on a political question. Burke was inexorable. To him the political question was so vivid, so real, so intense, as to make all personal sentiment no more than dust in the balance. Burke confronted Jacobinism with the relentlessness of a Jacobin. The rupture was never healed, and Fox and he had no relations with one another henceforth beyond such formal interviews as took place in the manager's box in Westminster Hall in connection with the impeachment.

A few months afterwards Burke published the *Appeal from the New to the Old Whigs*, a grave, calm, and most cogent vindication of the perfect consistency of his criticisms upon the English Revolution of 1688 and upon the French Revolution of 1789 with the doctrines of the great Whigs who conducted and afterwards defended in Anne's reign the transfer of the crown from James to William and Mary. The *Appeal* was justly accepted as a satisfactory performance for the purpose with which it was written. Events, however, were doing more than words could do, to confirm the public opinion of Burke's sagacity and foresight. He had always divined by the instinct of hatred that the French moderates must gradually be swept away by the Jacobins, and now it was all coming true. The humiliation of the king and queen after their capture at Varennes; the compulsory acceptance of the constitution; the plain incompetence of the new Legislative Assembly; the growing violence of the Parisian mob, and the ascendency of the

Jacobins at the Common Hall; the fierce day of the 20th of June (1792), when the mob flooded the Tuileries, and the bloodier day of the 10th of August, when the Swiss guard was massacred and the royal family flung into prison; the murders in the prisons in September; the trial and execution of the king in January (1793); the proscription of the Girondins in June, the execution of the queen in October—if we realize the impression likely to be made upon the sober and homely English imagination by such a heightening of horror by horror, we may easily understand how people came to listen to Burke's voice as the voice of inspiration, and to look on his burning anger as the holy fervour of a prophet of the Lord.

Fox still held to his old opinions as stoutly as he could, and condemned and opposed the war which England had declared against the French republic Burke, who was profoundly incapable of the meanness of letting personal estrangement blind his eyes to what was best for the commonwealth, kept hoping against hope that each new trait of excess in France would at length bring the great Whig leader to a better mind He used to declaim by the hour in the conclaves at Burlington House upon the necessity of securing Fox; upon the strength which his genius would lend to the administration in its task of grappling with the sanguinary giant; upon the impossibility, at least, of doing either with him or without him. Fox's most important political friends who had long wavered, at length, to Burke's great satisfaction, went over to the side of the Government. In July 1794, the duke of Portland, Lord Fitzwilliam, Windham, and Grenville took office under Pitt. Fox was left with a minority which was satirically said not to have been more than enough to fill a hackney coach. "That is a calumny," said one of the party, "we should have filled two." The war was prosecuted with the aid of both the great parliamentary parties of the country, and with the approval of the great bulk of the nation. Perhaps the one man in England who in his heart approved of it less than any other was William Pitt. The difference between Pitt and Burke was nearly as great as that between Burke and Fox. Burke would be content with nothing short of a crusade against France, and war to the death with her rulers. "I cannot persuade myself," he said, "that this war bears any the least resemblance to any that has ever existed in the world. I cannot persuade myself that any examples or any reasonings drawn from other wars and other politics are at all applicable to it" (*Corr.* iv. 219). Pitt, on the other hand, as Lord Russell truly says, treated Robespierre and Carnot as he would have treated any other French rulers, whose ambition was to be resisted, and whose interference in the affairs of other nations was to be checked. And he entered upon the matter in the spirit of a man of business, by sending ships to seize some islands belonging to France in the West Indies, so as to make certain of repayment of the expenses of the war.

In the summer of 1794 Burke was struck to the ground by a blow to his deepest affection in life, and he never recovered from it. His whole soul was wrapped up in his only son, of whose abilities he had the most extravagant estimate and hope. All the evidence goes to show that Richard Burke was one of the most presumptuous and empty-headed of human beings. "He is the most impudent and opiniative fellow I ever knew," said Wolfe Tone. Gilbert Elliott, a very different man, gives the same account. "Burke," he says, describing a dinner party at Lord Fitzwilliam's in 1793, "has now got such a train after him as would sink anybody but himself: his son, who is quite *nauseated* by all mankind; his brother who is liked better than his son, but is rather oppressive with animal spirits and brogue; and his cousin, William Burke, who is just returned unexpectedly from India, as much ruined as when he went years ago, and who is a fresh charge on any prospects of power Burke may ever have. Mrs Burke has in her train Miss French [Burke's niece], the most perfect *She Paddy* that ever was caught. Notwithstanding these disadvantages Burke is in himself a sort of power in the state. It is not too much to say that he is a sort of power in Europe, though totally without any of those means or the smallest share in them which give or maintain power in other men." Burke accepted the position of a power in Europe seriously. Though no man was ever more free from anything like the egoism of the intellectual coxcomb, yet he abounded in that active self-confidence and self-assertion which is natural in men who are conscious of great powers, and strenuous in promoting great causes. In the summer of 1791 he despatched his son to Coblentz to give advice to the royalist exiles, then under the direction of Calonne, and to report to Beaconsfield their disposition and prospects. Richard Burke was received with many compliments, but of course nothing came of his mission, and the only impression that remains with the reader of his prolix story is his tale of the two royal brothers, who afterwards became Louis XVIII. and Charles X., meeting after some parting, and embracing one another with many tears on board a boat in the middle of the Rhine, while some of the courtiers raised a cry of "Long live the king"—the king who had a few weeks before been carried back in triumph to his capital with Mayor Pétion in his coach. When we think of the pass to which things had come in Paris by this time, and of the unappeasable ferment that boiled round the court, there is a certain touch of the ludicrous in the notion of poor Richard Burke writing to Louis XVI. a letter of wise advice how to comport himself.

At the end of the same year, with the approval of his father, he started for Ireland as the adviser of the Catholic Association. He made a wretched emissary, and there was no limit to his arrogance, noisiness, and indiscretion. The Irish agitators were glad to give him two thousand guineas and to send him home. The mission is associated with a more important thing, his father's *Letters to Sir Hercules Langrishe*, advocating the admission of the Irish Catholics to the franchise. This short piece abounds richly in maxims of moral and political prudence. And Burke exhibited considerable courage in writing it; for many of its maxims seem to involve a contradiction, first, to the principles on which he withstood the movement in France, and second, to his attitude upon the subject of parliamentary reform. The contradiction is in fact only superficial. Burke was not the man to fall unawares into a trap of this kind. His defence of Catholic relief, and it had been the conviction of a life-time, was very properly founded on propositions which were true of Ireland, and were true neither of France nor of the quality of parliamentary representation in England. Yet Burke threw such breadth and generality over all he wrote that even these propositions, relative as they were, form a short manual of statesmanship.

At the close of the session of 1794 the impeachment of Hastings had come to an end, and Burke bade farewell to Parliament. Richard Burke was elected in his father's place at Malton. The king was bent on making the champion of the old order of Europe a peer. His title was to be Lord Beaconsfield, and it was designed to annex to the title an income for three lives. The patent was being made ready, when all was arrested by the sudden death of the son who was to Burke more than life. The old man's grief was agonizing and inconsolable. "The storm has gone over me," he wrote in words which are well known, but which can hardly be repeated too often for any who have an ear for the cadences of noble and pathetic speech,—"The storm has gone over me, and I lie like one of those old oaks which the late hurricane has scattered about me.

I am stripped of all my honours; I am torn up by the roots and lie prostrate on the earth. . . . I am alone. I have none to meet my enemies in the gate. . . . I live in an inverted order. They who ought to have succeeded me have gone before me. They who should have been to me as posterity are in the place of ancestors."

A pension of £2500 was all that Burke could now be persuaded to accept. The duke of Bedford and Lord Lauderdale made some remarks in Parliament upon this paltry reward to a man who, in conducting a great trial on the public behalf, had worked harder for nearly ten years than any minister in any cabinet of the reign. But it was not yet safe to kick up heels in face of the dying lion. The vileness of such criticism was punished, as it deserved to be, in the *Letter to a Noble Lord* (1796), in which Burke showed the usual art of all his compositions in shaking aside the insignificances of a subject. He turned mere personal defence and retaliation into an occasion for a lofty enforcement of constitutional principles, and this, too, with a relevancy and pertinence of consummate skilfulness. There was to be one more great effort before the end.

In the spring of 1796 Pitt's constant anxiety for peace had become more earnest than ever. He had found out the instability of the coalition and the power of France. Like the thrifty steward he was, he saw with growing concern the waste of the national resources and the strain upon commerce, with a public debt swollen to what then seemed the desperate sum of £400,000,000. Burke at the notion of negotiation flamed out in the *Letters on a Regicide Peace*, in some respects the most splendid of all his compositions. They glow with passion, and yet with all their rapidity is such steadfastness, the fervour of imagination is so skilfully tempered by close and plausible reasoning, and the whole is wrought with such strength and fire, that we hardly know where else to look either in Burke's own writings or elsewhere for such an exhibition of the rhetorical resources of our language. We cannot wonder that the whole nation was stirred to the very depths, or that they strengthened the aversion of the king, of Windham, and other important personages in the Government, against the plans of Pitt. The prudence of their drift must be settled by external considerations. Those who think that the French were likely to show a moderation and practical reasonableness in success, such as they had never shown in the hour of imminent ruin, will find Burke's judgment full of error and mischief. Those, on the contrary, who think that the nation which was on the very eve of surrendering itself to the Napoleonic absolutism was not in a hopeful humour for peace and the European order, will believe that Burke's protests were as perspicacious as they were powerful, and that anything which chilled the energy of the war was as fatal as he declared it to be.

When the third and most impressive of these astonishing productions came into the hands of the public, the writer was no more. Burke died on the 8th of July 1797. Fox, who with all his faults was never wanting in a fine and generous sensibility, proposed that there should be a public funeral, and that the body should lie among the illustrious dead in Westminster Abbey. Burke, however, had left strict injunctions that his burial should be private; and he was laid in the little church at Beaconsfield. It was the year of Campo Formio. So a black whirl and torment of rapine, violence, and fraud was encircling the Western World, as a life went out which, notwithstanding some eccentricities and some aberrations, had made great tides in human destiny very luminous. (J. MO.)

BURKE, Robert O'Hara (1821–1861), one of the great explorers of the continent of Australia, was born in 1821 at St Clerans in Galway, Ireland. He left the Belgian college where he had been educated to enter the military service of Austria, but in 1848 returned to Ireland, and obtained a post in the mounted police. He next went to Australia, and served for some time as police-inspector, first in Melbourne and then in the district of Beechworth, till the outbreak of the Crimean War induced him to return to Europe to take part in the campaign. Peace was restored, however, before he arrived, and he accordingly went back to Australia and resumed his connection with the police force. In 1860 he was appointed one of the leaders of a Government exploring expedition, and in this capacity had the honour of being one of the first Europeans to traverse the continent from south to north. A short account of the enterprise—so brilliantly successful in its achievements and so disastrous in its termination—is given in the article Australia, vol. iii. p. 106; and fuller details will be found in the *Journal of the Royal Geographical Society* for 1862. The remains of the explorer were interred by Howitt's relief party in 28° 20′ S. lat. and 141° E. long.

BURLAMAQUI, Jean Jacques (1694–1748), a celebrated writer on natural law, was born at Geneva on the 24th June 1694. He received a careful education, and while passing through his university course devoted himself with such success to the study of ethics and law of nature, that at the age of twenty-five he was designated honorary professor. Before taking possession of his chair he travelled through France and England, and made the acquaintance of the most eminent writers of the period. On his return he began his lectures, and soon gained a wide reputation, from the simplicity of his style and the precision of his views. He continued to lecture for fifteen years, when he was compelled to resign from ill-health. His fellow-citizens at once elected him a member of the council of state, and he gained as high a reputation for his practical sagacity as he had for his theoretical knowledge. He died at Geneva on the 3d April 1748. His works were *Principes du Droit Naturel*, 1747, and *Principes du Droit Politique*, 1751. These have passed through many editions, and were very extensively used as text-books. The most convenient collected edition is that by Dupin, in 5 vols., 1820. Burlamaqui's style is simple and clear, and his arrangement of the material good. His fundamental principle may be described as rational utilitarianism, and it in many ways resembles that of Cumberland.

BURLINGTON, a city and port of entry of the United States, capital of Chittenden county, in Vermont, 38 miles N.W. of Montpelier, in 44° 27′ N. lat., and 73° 10′ W. long. It has a fine situation on the eastern shore of Lake Champlain, and is laid out with great regularity around a central square. Its principal buildings are the Vermont University (which occupies the summit of the slope on which the city is built), the Vermont Episcopal Institute, the court-houses, a jail, a custom-house, and a marine-hospital. The university was founded in 1791, and was endowed by the State with 29,000 acres of land,—to which in 1865 were added 150,000 acres of national grant by the incorporation of the agricultural college. There is a medical school attached. Burlington carries on an extensive trade in lumber, and has the most important share in the shipping traffic of the lake. Its harbour is defended by a breakwater, and a lighthouse was erected at the mouth of the bay in 1862. To the north of the Onion River, but united to Burlington by a bridge, lies the flourishing village of Winooski, with factories and mills. The history of Burlington only dates from 1783; its first church from 1795, and its incorporation as a city from 1864. Population in 1870, 14,387.

BURLINGTON, a city and port of entry of the United States in Burlington county, New Jersey, 18 miles N.E. of Philadelphia, on the Delaware, in 40° 5′ N. lat. and 73°

10′ W. long. It is well built, has an abundant supply of water, and forms a favourite summer resort for the inhabitants of Philadelphia. Its educational institutions are of considerable importance, and comprise an Episcopal college, founded in 1846; St Mary's Hall, also under Episcopalian management; two large boarding schools; and a number of public schools, which are well endowed. There is also a town-hall and a valuable library. Though it has greatly declined with the rise of Philadelphia, Burlington still maintains a respectable shipping trade; in 1871 it had 131 vessels with a registered tonnage of 12,525. The first settlement of the city dates from 1667, and was principally due to a number of Quakers. New Beverly, as the place was originally called, grew rapidly in importance, and was the seat of the Government of New Jersey till 1790. It had a large trade with the West Indies, and was raised to the rank of a bishopric, Queen Anne endowing the church with an extensive estate. Population in 1870, 5817.
